The foregoing features of the patent situation, however, affect practical electrical workers only indirectly. The most serious feature to them is the ease with which worthless patents may be obtained—if one has the necessary cash. This is not the fault of the governmental patent system, any more than the ease with which the unsophisticated can be fleeced by promoters and unscrupulous brokers is the fault of the legal system of a State. Patent attorneys, as a class, are among the most rigidly honorable of professional men, but the list includes also black sheep who do not hesitate to urge a client to take out a patent for an "invention" that they know absolutely to be not worth a solitary dollar on an honest basis. In view of this well-known fact, together with the condition mentioned in the beginning of the preceding paragraph, it behooves the practical worker beset with new ideas to submit those ideas to the critical examination of some one better qualified than he is to judge their merits before rushing off to a patent mill and sacrificing hard-earned money. But if the struggling inventor *will* rely on his own judgment and is determined to have a patent at all hazards, he should at least steer clear of the patent attorneys who boast of never having a claim rejected or guarantee to secure a patent regardless of the character of the invention; no conscientious attorney can claim any such ability.

The Exhaust Pressure of a Gas Engine.

Almost all of the earlier text books on the gas engine explained the high pressure of the exhaust gases on the ground that the necessity for high compression pressures made it impractical to expand the burning gases below the ruling exhaust pressures, which were then about 30 to 40 pounds above atmospheric pressure. That high compression is necessary to high efficiency is, of course, well recognized, and it is also perfectly well known that the higher the compression pressure, the higher will be the exhaust pressure, other conditions being unchanged. Practical gas engine designers, however, have long ago learned that the requirement of high compression pressure does not necessarily entail high exhaust pressure, because it is not at all necessary, academically, to maintain any particular ratio between the two. A given compression pressure can be obtained with a certain cylinder clearance and a throttled admission that would be obtained with a larger clearance and perfectly free admission, and the exhaust pressure would be much lower in the first case than in the second; but the output of the engine would also be lower. The question of exhaust pressure, therefore, is determined largely by the cost of manufacture, although other considerations enter also. If the weight of the engine per unit of output at a given piston speed could be made anything, regardless of cost, it would be a relatively simple matter to get the exhaust pressure down to a few pounds above the atmosphere. This is clearly indicated, aside from any theoretical consideration, by the changes in the exhaust pressure of a throttling gas engine operating under widely varying loads.

THE CONSTRUCTION OF A TWO-PHASE SYNCHRONIZER.

BY PAUL C. PERCY.

The accompanying drawings and description relate to a two-phase synchronism indicator of the "revolving light" type, similar to the apparatus described in the last number of this paper for three-phase work. In the present case, there are two transformers, as before, but one of these is a two-phase transformer; four incandescent lamps are required instead of three. Such an outfit may be constructed with extremely limited facilities in the way of machinery and tools; the greatest care must be exercised, however, in applying and maintaining the insulation of the transformers.

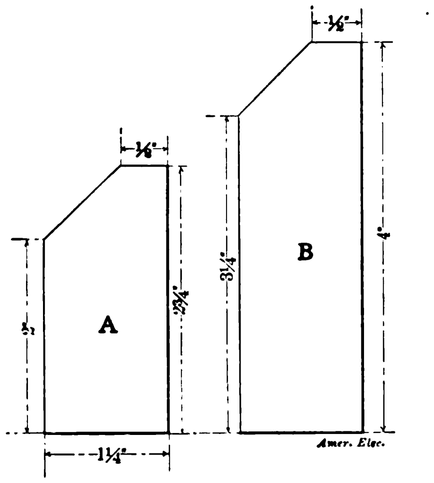

FIG. 1.

The single-phase transformer is built up of rectangular strips of sheet steel each having one corner cut off, as indicated in Fig. 1; there must be two sizes of these strips, as the engraving shows, and of the dimensions specified in the sketch. The thickness of the sheet steel may be 25 mils; this would be too thick for ordinary transformer work, but as these transformers are in circuit only a very short time the increased core loss due to the thick sheets is of no importance.

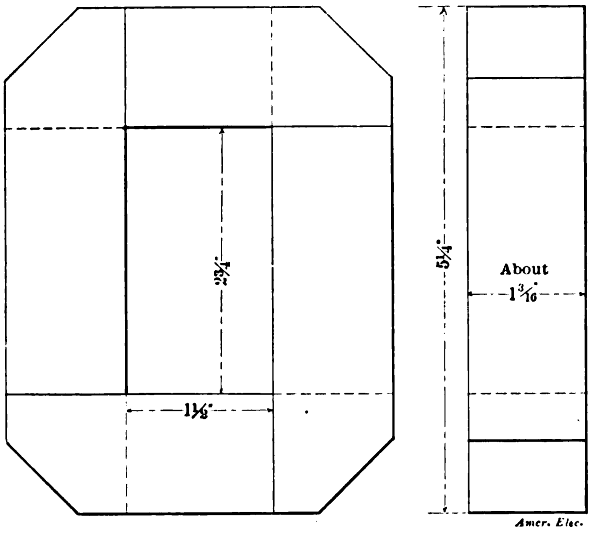

FIG. 2.—COMPLETE CORE OF SINGLE-PHASE TRANSFORMER.

There will be required 80 strips of each size shown by Fig. 1, and these are to be built up to form a core of the shape and dimensions shown in Fig. 2. The core is 40 sheets thick and these 40 sheets should compress to about 1 3-16 inches, as indicated by the dimension stated on the edge view of the core. The strips must be staggered, so as to break joints, the first layer being put down as shown by Fig. 3, the second layer as shown by Fig. 4, the third layer like the first, and so on.

Before the core can be built up, the coils must be wound, taped and baked. The coils are wound in fibre bobbins, the heads of which are made of 1/8-inch hard fibre of the shape and size shown by Fig. 5. Two of these heads are fastened to the tube of the bobbin, one at each end, by means of thick shellac varnish. The tube consists of a sheet of 1-16-inch fibre 2 3/4 inches wide and 5 1/4 inches long, bent into tubular form so as to fit in the square openings in the heads. The bobbin must be mounted on a square wooden mandrel and the heads backed up by blocks tacked on the sides of the mandrel, so that the wire will not press the heads off the ends of the tube.

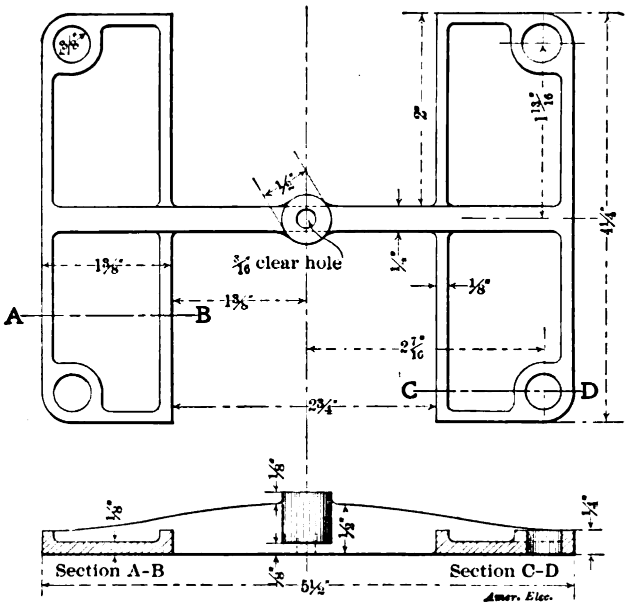

FIG. 7.—CLAMPING PLATE; SINGLE-PHASE TRANSFORMER.

The secondary coil is wound on the bobbin first. It consists of 3 layers of No. 20 double-cotton-covered magnet wire in each bobbin (there are two, one on each leg of the core) with 60 turns in each layer: 180 turns in each coil. After winding this coil, it must be covered with six layers of oiled linen 0.01 inch thick, wrapped in one continuous strip the full width of the bobbin between heads (2 1/2 inches). Then four pieces of hard fibre 1-16 inch thick and of the shape and size shown by Fig. 6 must be glued to the inner face of each head so that when the primary wire is wound on top of the secondary the wires cannot pull down between the head and the edges of the oiled linen.

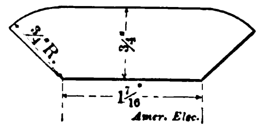

FIG. 6.

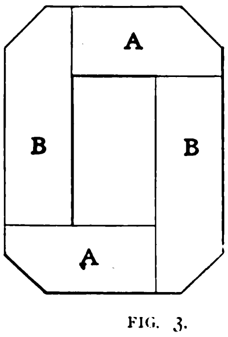

FIG. 3.

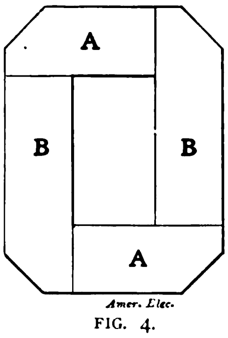

FIG. 4.

The primary winding in each bobbin consists of 8275 turns of No. 36 double-silk-covered wire, the silk covering being 2 mils thick; that is to say, the diameter of the wire measured over the insulation is 4 mils greater than the bare diameter. After winding on the first four layers of the primary, these should be covered with a thickness of the 0.01-in. oiled linen; a layer of this should be put in on top of each four layers of wire through the winding; six strips will therefore be required for this purpose.

The outside of the complete coil should be covered with six layers of oiled linen and a protecting layer or two of heavy duck, the outer layer of this being heavily varnished. The two primary coils are to be connected in series so that if direct current were passed through them they would both magnetize the core in the same direction as to the complete magnetic circuit. The two secondary coils are also connected in series, and in agreement with each other.

After the core-plates are assembled, with the coils in place, of course, they are to be clamped tightly together by means of two brass plates of the shape and dimensions shown by Fig. 7, and five steel rods 3-16 inch in diameter, threaded at both ends; the clamping plates are to be drawn together by means of nuts on the ends of the rods. The plates must be insulated from the core by means of hard fibre facings 1/8

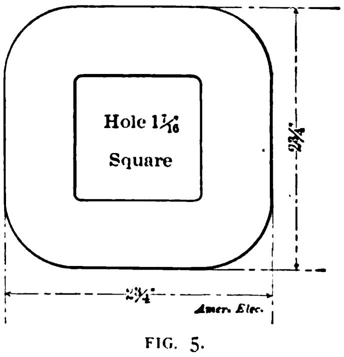

FIG. 5.

inch thick, the full size of the plate outlines. The rods in the four corner holes are insulated from the clamping plates by means of fibre bushings, one of which is shown in Fig. 8; the central bolt need not be insulated.

The two-phase transformer core is made up of sheet steel strips of four sizes; the shapes and dimensions of these are given in Fig. 9. The complete core, without the coils, is shown in Fig. 10; it is built up in somewhat the same manner as the core of the single-phase transformer. The first layer is put down as shown in Fig. 11, the second layer as in Fig. 12, the third layer like the first, and so on. The complete core must be 40 sheets thick.

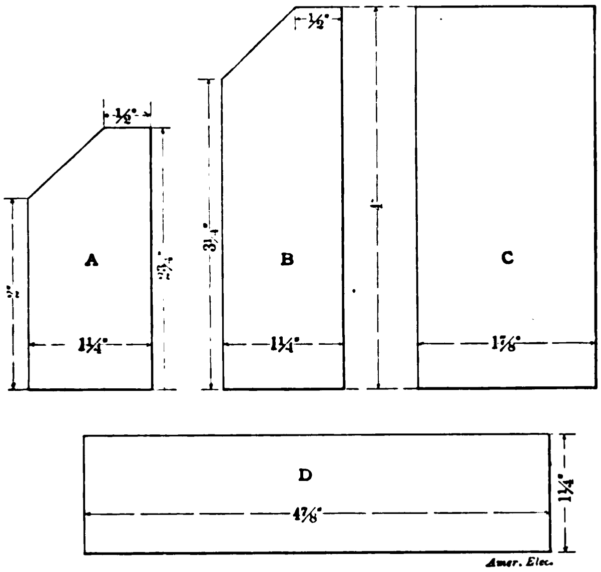

FIG. 9.—CORE STRIPS.

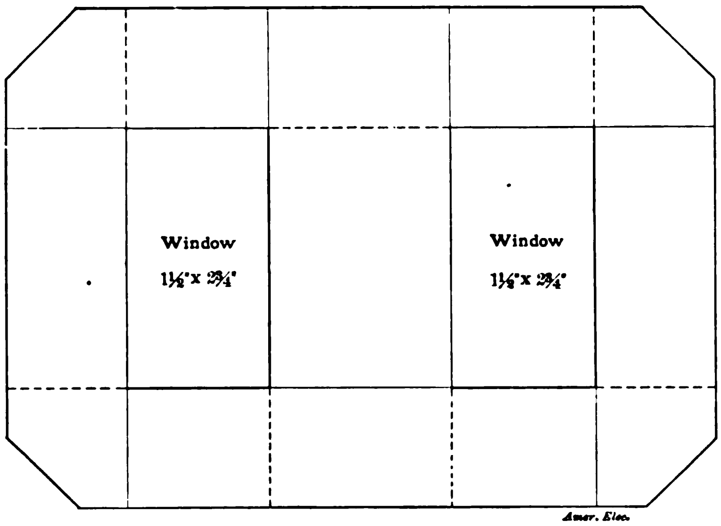

FIG. 10.—TWO-PHASE TRANSFORMER CORE.

This transformer has two distinct sets of coils, one set located on each of the outside legs, *B*, *B*, Figs. 11 and 12. The bobbins are of exactly the same size and construction as those described for the single-phase transformer. The secondary coil on each leg consists of 720 turns of No. 20 double cotton-covered wire, which will make about 12 layers. A tap must be brought out from the middle of each secondary coil; that is to say, after 360 turns have been wound a loop should be carried through a hole in one of the heads of the fibre bobbin and the winding continued without cutting the wire. The object of this middle tap will appear later on. Each secondary coil must be covered with six layers of 0.01-inch oiled linen and four fibre cheek pieces glued to the inner face of each bobbin, as in the case of the single-phase transformer.

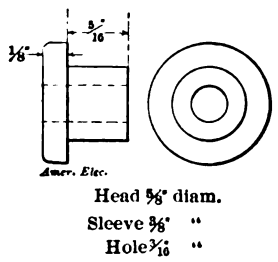

FIG. 8.—TIE-ROD INSULATOR.

Each of the two primary coils consists of 16,550 turns of No. 36 double silk-covered wire. A layer of 0.01-inch oiled linen must be inserted after each third layer of the primary winding, and each complete primary coil protected on the outside by a wrapping of six layers of oiled linen and one or two layers of heavy duck, the outside layer being heavily varnished.

The core strips are compressed by means of two brass clamping plates of the shape and dimensions shown by Fig. 13, and six ¼-inch steel rods with nuts and washers at both ends. The rods must be prevented from metallic contact with the clamping plates by means of insulating sleeves, as in the case of the single-phase transformer; the dimensions of the sleeve are as stated in Fig. 14.

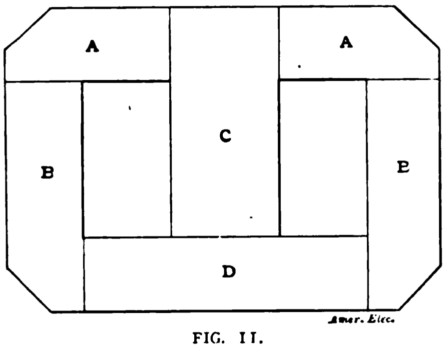

FIG. 11.

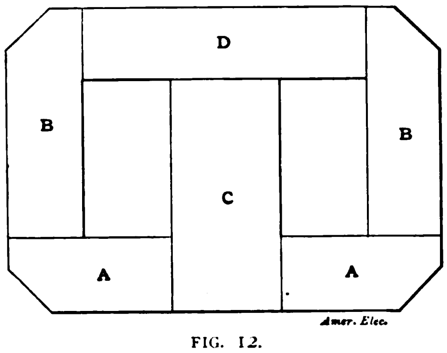

FIG. 12.

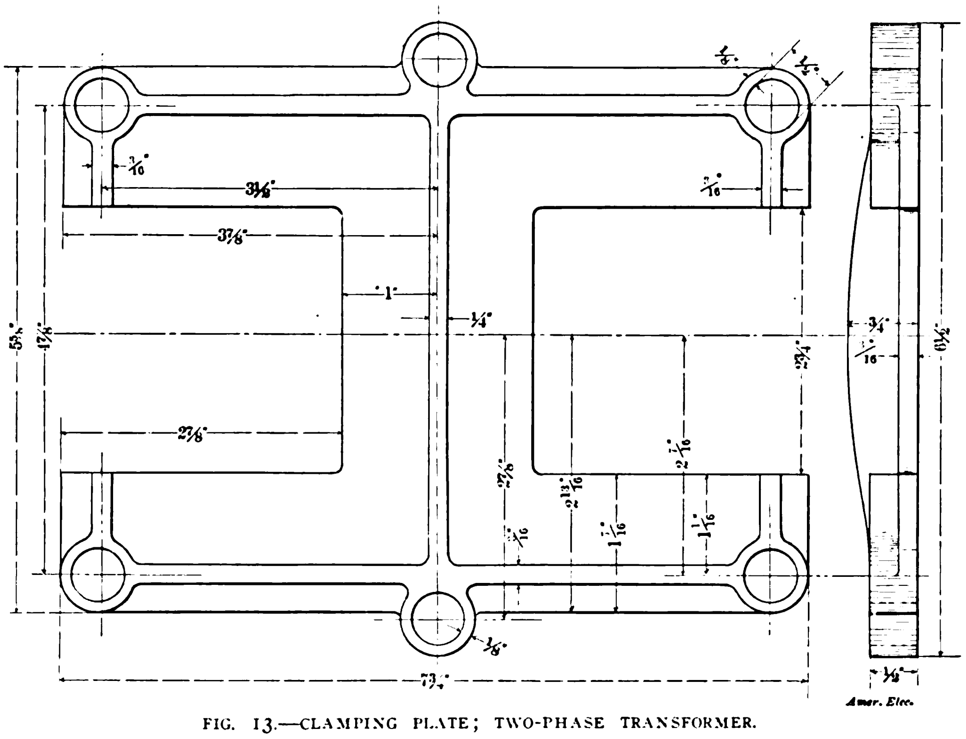

FIG. 13.—CLAMPING PLATE; TWO-PHASE TRANSFORMER.

The connections of the transformers and lamps are shown by Fig. 15. The primary winding of the single-phase transformer must be connected to phase *A* of the bus-bars through a double-pole switch. One terminal of the secondary winding is connected to the neutral point of the lamp circuit which is X-connected, and the other terminal is connected to both of the middle taps of the secondary windings on the two-phase transformer. The free terminals of the two-phase secondaries are connected to the free terminals of the four lamps, as shown in the diagram, and the primary windings of the two-phase transformer are connected through the usual plugs and sockets to the main switch of the incoming generator. If the connections are properly made with respect to the phase relations of the various coils, the lamps will glow in succession as the phases of the incoming generator successively agree with and oppose phase *A* of the system; this will give the effect of a revolving light, the speed of which will be proportional to the difference between the speed of the incoming generator and that of the machines already in circuit, and the direction clockwise. As the incoming generator approaches synchronism, the speed of the "revolving light" will decrease, and when exact synchronism is attained, the top lamp (*a*) of the group will glow steadily and the others will remain dark.

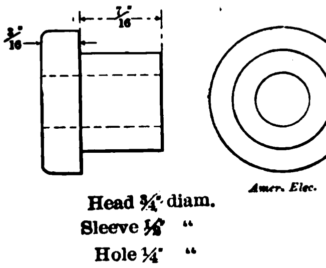

FIG. 14.—TIE-ROD INSULATOR.

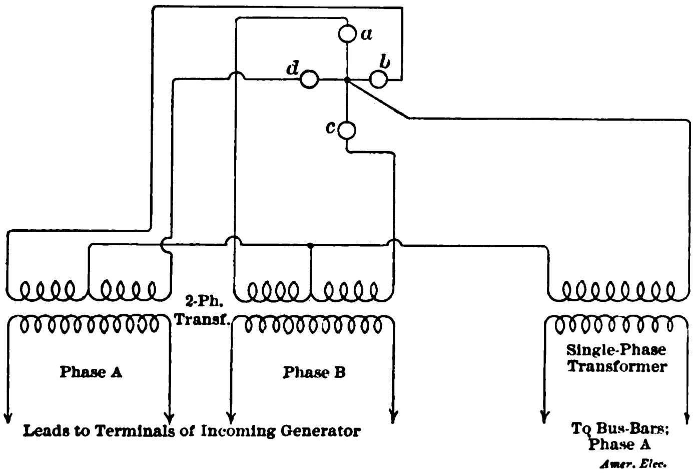

FIG. 15.—DIAGRAM OF CONNECTIONS.

It should be remembered that the steady glowing of either of the other lamps alone indicates identical speeds at the generators, but not coincidence of phases; if the lamp *b* glow steadily, it indicates that the generators are running at the same speed, but that phase *B* of the incoming machine is in step with the phase *A* of the system, and the machine must, of course, not be thrown in.

The lamps should be rated at 100 volts and of low efficiency—say 64 watts consumption. Both of the transformers are designed for a primary e.m.f. of 2300 volts, and the two-phase transformer for 100 volts per complete secondary coil (50 volts between the taps and free terminals); the single-phase secondary should give 50 volts. All of the secondary voltages should be measured, however, and lamps chosen which are of at least twice the voltage of the single-phase secondary, and preferably a volt or two higher.

It is as well to repeat the warning given in the beginning of this article to the effect that the transformer windings must be most carefully handled and insulated in view of the high primary voltage. It is also essential that the rods which draw the clamping plates together be reliably insulated from the plates and from the core; it will be found a good plan to wrap them with a couple of layers of tape after the core is assembled.

◆

Gas for Power—A report from U. S. Consul Mahin, Nottingham, England, says: A large undertaking is now being developed some 30 miles southwest of this city, where material is abundant and industries to consume the gas are numerous. A company, incorporated with a capital of $1,000,000 proposes to supply gas to a territory covering 120 square miles, generated at a central station near the middle of this area and at several other stations to be placed at convenient points. It is stated that the gas will be transmitted long distances through pipe mains laid underground without depositing any tar. The purified gas, after being compressed in horizonatl compressors driven by a steam engine with Corliss gear, enters the trunk mains at about 7 pounds pressure per square inch. At present it is intended to take the gas about 6 miles from the central station, which is capable of producing daily about 40,000,000 cubic feet of gas. The population of the entire territory of 120 square miles, to be eventually supplied with gas, is 640,000. The stack costs from 60 cents to $1.75 per ton, dependent upon distance from a coal pit. The price of the gas to the consumer varies from 2d. to 4d. (4 to 8 cents) per 1000 cubic feet. This is from one-seventh to one-fifteenth the price of other gas in this section. The process altogether is claimed to be by far the cheapest way of making coal gas known at present.

ENGINE ROOM MANAGEMENT.

BY WALTER W. EDWARDS.

Assuming that fires have been lighted under the boilers and that about 20 pounds of steam is showing on the gauges, the engineer in charge of a steam plant should, at this juncture, leave his chief fireman in charge of the fireroom while he turns his undivided attention to the machinery in the engine room. If there has been no steam in the boilers for a few days, the boiler stop valves will be shut, and it is the best practice to open these valves while the steam pressure in the boilers is still low. If the practice is followed of waiting until the full working pressure on the boilers is reached before opening the valves, there is a great deal of unnecessary strain brought on the main steam pipes because of the greater difference in temperature between the pipe and the steam than there would be between the pipe and low pressure steam. The unequal expansion due to this difference in temperature is always excessive, and as the strain of the high pressure is also brought to bear at the same time, there is much more danger of rupture than would be the case if steam had been admitted when the pressure was low.

Of course, when the full pressure already exists on the boilers there is nothing to do but to admit the high pressure steam. In any case, all the drains on the main steam line should be opened first, and then the main stop valve barely eased off its seat so that a little steam will blow through the line and out at the drains. By doing this carefully, the entire pipe can be warmed up to the temperature of the steam without having any pressure on it at all. By following this method only strains due to expansion are set up in the steam pipe, and these are applied so gradually that the danger of a rupture or of causing the joints to leak is reduced to almost nothing. When the line of pipe is thoroughly warmed up, the drains may be closed one at a time and the pressure will gradually rise until equal to the boiler pressure. The main stop valves on the boilers then should be opened wide.

It may seem at first thought that directions for opening or closing a valve would be unnecessary, but an engineer of experience around steam plants knows to his sorrow that such is not the case. A valve, whether it is large or small, should be opened slowly until the desired amount of opening is obtained. If it is to be wide open, the valve stem should be turned until the valve cannot be opened any wider; then it should be turned back about one quarter of a turn and left there. Under no circumstances should it be jammed wide open; if it is, the expansion that takes place when the valve becomes hot often makes it very hard to turn the valve stem back again, and because of this, an oiler or fireman may conclude that the valve is not open at all, and put his pocket monkey wrench on the valve wheel and give it a jerk. The natural result is that the valve stem is twisted more and more each time until some day it breaks. A little thing like a valve stem twisted off does not bother our would-be engineer at all, because he knows that he can still open and close the valve by means of a six-inch Stilson wrench which he immediately proceeds to get. A small Stilson is as easily carried as a small monkey wrench, so he thinks. While on this subject, a word of protest against using a wrench to open and close valves may not be amiss. If the valves of a plant are kept in proper condition, there is no excuse for the practice of carrying a wrench in the hip pocket for use on valve stems or wheels. The only advantage that it offers is that if the hand wheel on the stem should be hot, the danger of burning the hand is obviated, but if a little waste is carried in the pocket even this excuse fails. In a well-regulated plant the monkey wrench is left on the tool bench where it belongs.

The question of whether steam shall be left on the main steam pipe all night or not is one that has provoked much discussion at one time or another. Each way has its advantages and disadvantages so that a decision must be a choice or compromise between them. If steam is left on the pipe, a considerable quantity of steam is condensed during the night, and therefore more heat taken from the boilers. This in itself is of small consequence as the boiler fires are banked at night so that the difference in the amount of coal burned would be very trifling, but unless very efficient means of draining the steam line is provided, the water of condensation stands in the pipe with a full head of steam on it, and this is certain to cause leaks and eventually the blowing out of gaskets between the flanges of pipe joints.

The reason a line of steam piping will leak when filled with water under boiler pressure and will hold tight when subjected to the same pressure without the water, is to be found in the fact that the water will fall in temperature and yet have its pressure maintained by the steam in the boiler. As the water in the pipe cools, the pipe contracts and this opens leaks that do not exist when the pipe is expanded. The contraction of the pipe lengthwise reduces the grip that the flanges have on the gaskets between them, and the pressure forces the water out or ruptures the gaskets between the bolt holes of the flanges. With steam the case is wholly different. The temperture of saturated steam depends on its pressure, and as the temperature falls the pressure also must fall, so that when the steam line has cooled and contracted there is no pressure on it, and consequently it does not leak. If there is efficient means of drainage and the steam line has been given a proper incline so that the water runs to the drains, this objection to leaving steam on the pipe over night no longer holds good.

Another disadvantage of leaving the steam on an engine supply pipe and allowing it to fill with water, as shown in Fig. 1, is the very great danger that exists when the pipe is drained in the morning by means of the small drain under the throttle. The lower part of the pipe is filled with cold water while the upper part is filled with steam having a temperature of 300° or 400°. This means that at the surface of the water in the pipe there is a very great difference in temperature within a length of less than an inch and as the water is drained out, the various parts of the cold pipe pass almost instantly from a moderate temperature to the high temperature of the steam. The effect on the pipe of such treatment can well be compared to the effect that would be produced if a plug of steel having a larger diameter than that of the pipe were forced through the latter. Every time it is done this action is repeated, so that it is little wonder such treatment often results in the rupture of the pipe line and loss of life.

Both of these disadvantages may be overcome by automatically draining the pipe through an efficient steam trap, and with this provision, leaving the steam on the line at all times has the very great advantage that the racking due to warming up is avoided. There is also less labor involved if the steam is left on, as climbing up on the boilers to handle large valves is always a hot, disagreeable duty.

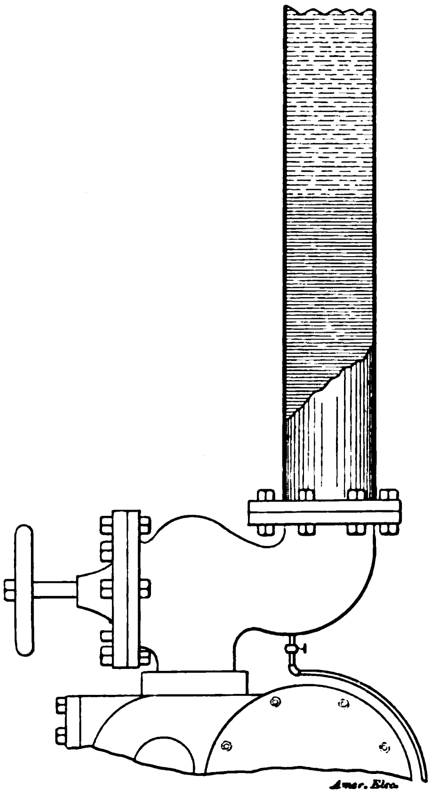

FIG. 1.

When full pressure steam is up to the throttle and the engineer has made sure that all water of condensation has been removed, he should next turn his attention to the engine itself. The cylinder drains should be looked at so as to make sure that they were opened when the engine was stopped. It is always customary to fit a water service to marine engines so that cold water may be circulated around all bearings, which are cored out for this purpose. This practice is being adopted more or less in the larger sizes of stationary engines, and where this is done water should be turned on some time before the engine is started so as to get all the bearings as cool as possible. The oil cups should next be looked after and started to feeding. If there is a condenser attached, all the water valves should be inspected to see that they are open.

If it is possible, the circulating water should be started first and then the air-pump, so as to have a good vacuum before the main engine is started. If a steam jacket is fitted to the low-pressure cylinder, steam should be turned on and the reducing valve set so as to give about 10 pounds pressure on the jacket. The trap on the jacket drain should be inspected so as to be sure that it discharges properly. After all these precautions have been taken, the throttle valve should be opened just enough to allow steam to enter the cylinder, but not enough to cause the engine to turn. Warming up in this way makes it certain that the cylinder will not be cracked by a sudden rush of steam against cold metal. When the engine is thoroughly warmed up, the throttle may be opened wider and the engine allowed to turn slowly. The drains should be kept open throughout the whole process of warming, and should not be closed until the engine is fully up to speed.

After the engine is running, the oil feeds should be cut down so as to give each bearing the amount of oil that experience has shown that it needs. The oiler or the engineer on duty, if there is no oiler, should regularly feel of each bearing or joint where it is possible that heat may be developed by friction. The crank-pins and cross-heads may be felt by the hand with a little practice, as well as bearings that are stationary. The hand or finger should be extended toward the bearing very slowly until the moving part just touches the fingers as it passes. In doing this, care should be taken and such a part of the revolution chosen so that the moving parts will be moving away from the fingers an instant after contact or an accident may result. This knack of "feeling" an engine is easily acquired, and is not nearly so dangerous as it may seem.

During the running of the engine there are two evils against which the engineer must always be on guard. One is priming in the boilers, and the other is hot bearings on the engine. Neither of these troubles gives much warning of its approach, and it is consequently imperative that the engineer shall at all times be alert and watchful. Priming usually makes its presence known by a slapping sound in the cylinder, which is produced by the piston striking the water and throwing it against the cylinder heads. As soon as this sound is heard, the cylinder drains should be opened and a hurried inspection made of the separator to see if it is working all right. If there is considerable water in the glass on the separator, the by-pass on the trap through which it drains should be opened wide.

The speed of the engine should not be reduced except as a last resort, as this means the advertising of the difficulty to the entire establishment, or in the case of an electric light central station, to the entire city. When these precautions have been taken in the engine room, the engineer should visit the boilers and order the firemen to cover the fires of the priming boiler with fresh fuel. Meanwhile, the water level in the gauge glasses should be noted, and if any of them show high water, the bottom blow should be opened and the water brought down to its proper level. These precautions will, in almost every case, stop the priming, but if they do not, the stop valve on the offending boiler should be partially closed so as to wire draw the steam from that boiler and thus dry it. Dirty water may cause priming, and if this cause is suspected, the bottom blow should be freely used. When the priming has been stopped by some or all of these remedies, the bypass on the separator trap may be closed, and also the cylinder drains.

Hot bearings may result from a number of causes, such as lack of oil, grit or dirt of some sort, badly fitted brasses, poor adjustment of brasses or a bearing too small for its work. A hot bearing caused by a lack of oil is in every case the direct result of carelessness on the part of the attendant. It is no excuse to say that the oil pipes from the cups became clogged with dirt; that is what the attendant is paid to prevent, and if he does not, he is not doing his duty. When the heating is caused by grit in the oil there is more excuse for a hot bearing, but careful watching will usually enable the engineer to catch it in time, and by a liberal supply of clean oil the dirt can usually be washed away. Badly fitted brasses can cause heating by concentrating the pressure of the journal on an insufficient bearing surface, thus causing excessive friction at one point. As the area of the bearing surface may be reduced by poor workmanship in fitting, by the brasses being out of line, or by the bearing having been originally of too small a size, it follows that any of these may cause hot bearings. The remedy is to fit the brass properly, line up the engine, or have larger brasses made, as the case may be.

When brasses are keyed up too tightly after making repairs, the friction is, of course, excessive and the bearing is very quickly heated. Besides heating quickly from this cause, the time at which it occurs is just after the engine is started, and hence the engineer and oiler are very apt to have their attention called elsewhere, and therefore cannot concentrate it on the engine. If a liberal supply of oil will not stop the heating, recourse must be had to other means. Flowers of sulphur, or graphite may be mixed with the oil and fed to the bearing, or a little soft soap or soapy water will reduce the heat; if these fail, the engine must be stopped and the brasses loosened. When using soapy water it is well to have the water heated some because cold water may crack the brasses if they are very hot. Cold water will cause the outside of the brass to contract and compress the inner parts, so that when the inner parts are also cooled, the brass grips the journal and will always cause heating until it is refitted. When a bearing is cooled by the use of water, it should be immediately flooded with oil as soon as the water is shut off, as the water will undoubtedly wash all the oil out of the bearing.

Incessant vigilance is essential to successful engine management; a careful attention to duty when on watch, a thorough knowledge of the business and a neat, well-kept engine room are characteristics that every engineer should strive to acquire to the highest degree.

TESTING RECORDING WATTMETERS.

BY GEO. T. HANCHETT.

The recording wattmeter is hardly an instrument of precision; it is considered commercially accurate when reading within 2 per cent. Its error varies with its load, the general tendency being to run slow on light loads and slow on heavy loads. This is due to the peculiar way in which the friction of the instrument affects its accuracy. For instance, if the frictional load of the instrument demands a torque equivalent to a certain number of watts, say 30, and the instrument be set to be correct on only one load, on low loads the frictional error, which is fairly constant, will be a larger percentage of the torque of the instrument, and above this point the relation will be reversed. Such instruments are generally equipped with a starting coil, which is intended to just compensate for the frictional load. This starting coil is of fine wire connected in series with the armature, and its field influences the latter. With the coil connected as stated, the torque of the armature, due to the starting coil, becomes proportional to the square of the applied voltage. Therefore, it is evident that if there is any departure from the voltage at which the instrument is intended to run, the torque due to the starting coil will become greater or less than the friction torque which it is intended to balance.

As it is impossible to have constant voltage, and also impossible to set the starting coil for absolutely correct compensation, the ordinary method of testing a wattmeter on a constant load and checking it with a voltmeter and ammeter is not satisfactory. From the consumer's point of view the only really satisfactory test is one made over a complete cycle of 24 hours, covering all the varying loads which are employed in practice on that particular instrument. To do this with a voltmeter and ammeter, taking periodic readings, is tedious and expensive work, and a better method is to use a second recording wattmeter, which is known to be correct, and install it in series with the first one. If this meter is calibrated in the laboratory, both before and after the test and while recording a number of different loads, its readings can be relied upon when proper corrections are applied. The actual work of testing a consumer's wattmeter is therefore largely eliminated, for the only thing necessary to do on the ground is to cut the standard meter in circuit, read both meters, and 24 hours later read and remove the standard instrument. It is not even necessary to know the elapsed time precisely.

The potential coil of the standard instrument should, of course, be connected back of the instrument to be tested, in order to prevent any flow of current in the standard instrument from being registered on the meter to be tested and thereby causing the reading to be in error. In doing this there is, of course, a slight error due to the fact that the potential coils of the standard instrument are not connected to the same terminal of the instrument to be tested. For closer accuracy, therefore, it is better to connect the potential winding of the standard meter to the same point as the potential winding of the meter to be tested, and knowing the resistance of the former winding and (in this case) the elapsed time, a proper correction can be applied.

The recording wattmeter as usually built is not a very desirable or convenient instrument for connecting in a service circuit. For testing apparatus, the writer has found it convenient to adapt standard meters to the purpose, and two forms which have been found useful are shown in the accompanying illustration. The meters themselves are ordinary instruments bought on the market; but their cases are removed, and the mechanisms are installed in wooden cases equipped with three adjustable legs by means of which the instruments may be leveled.

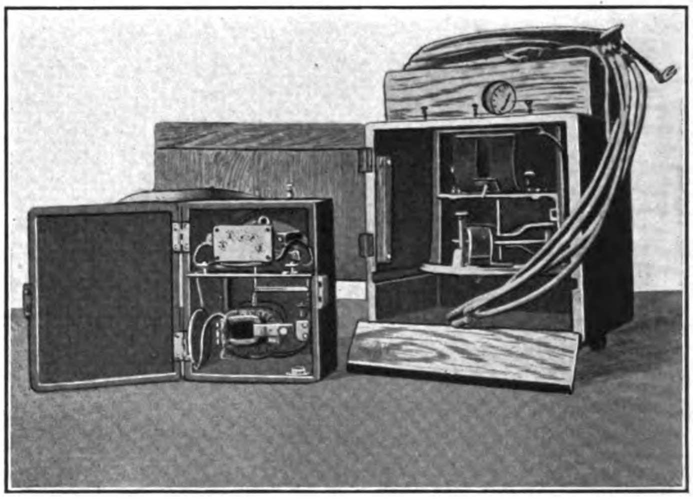

FIG. 1.—PORTABLE WATTMETERS FOR TESTING PURPOSES.

The larger instrument is equipped with four leads and terminals, one lead going to each series coil terminal. This enables one to connect the series coils in series or in multiple with each other, or on the three-wire plan. By building the boxes a little larger there is room for these leads underneath the instrument itself. The revolving disc of the instrument is raised or lowered by means of a spring and a screw which shows in the foreground; upon slacking off this screw the spring lifts the disc and the spindle of the instrument is thereby raised from its jewel, thereby enabling the instrument to stand transportation.

The first dial is equipped with a long delicate pointer, and a large dial divided into 100 parts in order that it may be read more closely is substituted for the regular dial. A small bullseye in the top of the box makes it convenient to read this dial and the one next to it. The instrument is equipped with two potential coils, for 240 and 120 volts respectively. Three binding posts on the top of the case make it easy for either the one or the other to be connected in circuit. It will be noted that the case has two doors; the upper door can be locked, thereby shielding the instrument from interference, when the lower door is opened to permit the leads to be led off to any convenient point. Each of the series coils of this instrument has a capacity of 50 amperes, so that when they are connected in multiple the meter will measure a load taking 100 amperes. This with the combination of the shunt coils gives the instrument a wide range of possibilities.

The smaller instrument shown in the engraving is connected on the same plan and installed in an ordinary portable instrument box. This instrument is not equipped with leads, however; the terminals of the two series coils are carried to four binding posts on the back of the case and the potential coil terminals are brought out on the top. A small level is screwed to the floor of the box, thereby enabling the user to properly adjust the meter with reference to the vertical before a test is made. Both of these outfits are "home-made" as far as the installation of the meters in their boxes is concerned, and the addition of leads, screws and potential coils. They have proven very serviceable for the work for which they were intended, and have saved a great deal of valuable time; it is because of their advantages in these respects that the writer recommends the arrangement for general work.

A wattmeter test of the kind mentioned herein has a value which the ordinary voltmeter and ammeter test has not. In the first place, it tests the entire instrument and will detect the possibility of a wrong recording mechanism being installed in the instrument to be tested, or the use of a wrong constant, which the rotation does not do. It will also detect any tendency of the instrument to stick. It often happens that a correctly indicating recording wattmeter will stick, due to some very slight obstruction, and will start up again after a jar has removed the obstruction.

An instrument can be modified into the form described at an expense not exceeding $10 in addition to the cost of the instrument itself, and it is useful not only for testing other meters, but for any work where watt-hour consumption is involved, such as life tests on lamps and the like.

In testing meters which measure the input of elevator motors or other machinery where the power fluctuates rapidly, an instrument of this kind is the only satisfactory apparatus which will integrate the fluctuations and give a correct check upon the meter which is used for commercially measuring the load.

In three-wire testing the use of such an instrument obviates the necessity for two ammeters, or at least two shunts and periodic connection. For all of these reasons the instrument has appeared to the writer to be worth while in many cases, and he has ventured to illustrate and describe it in the hope that others may find it so.

PLUG AND SOCKET CONNECTORS FOR ELECTRICAL TESTING ROOMS.

BY T. C. EMERSON.

Ordinary screw binding posts and common insulated wire are not at all satisfactory for making test connections. Wires after being tightened under screw binding posts a few times become compressed, bent out of shape and nicked and are apt to break off. The break may occur in some circuit, such as the field connections of a shunt-wound motor, where results could be very serious. There is also a tendency on the part of test men to set up the binding screws too tight, using plyers as a lever and frequently twisting the screws off. Moreover, ordinary binding posts when subjected to the vibrations of a running machine will usually work loose.

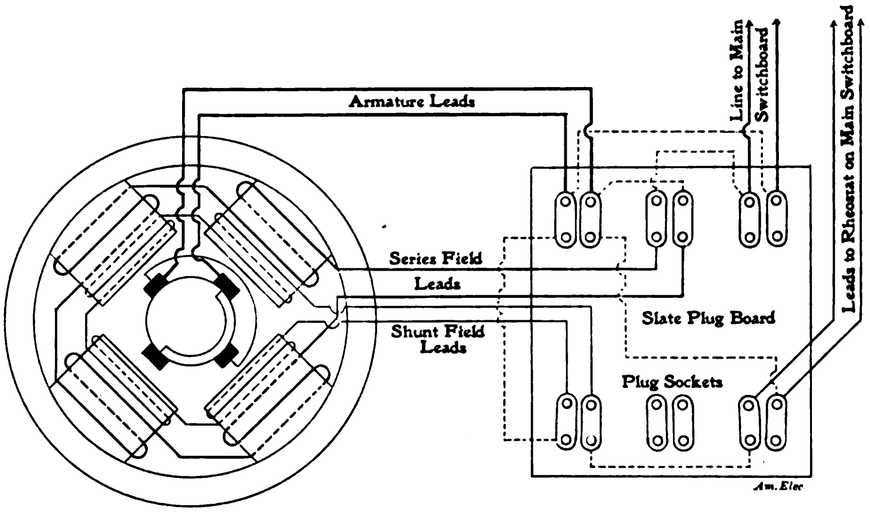

FIG. 2.—DIAGRAM OF CONNECTIONS.

The method adopted for connecting up apparatus in the electrical laboratory at Pratt Institute, Brooklyn, N. Y., has been found a very satisfactory one. Here the terminals from the different parts of the apparatus, switchboard instruments or rheostats are brought to brass sockets mounted on slate slabs. Brass split plugs, which make reliable contact in the sockets and fit firmly enough not to be easily displaced attached to flexible cables, are provided for connecting the sockets. The cables are of various lengths. Some have plugs on both ends and some have a plug on one end only and a short piece of about No. 6 copper wire soldered to the other end; this wire terminal will enter readily into the binding posts of measuring instruments and rheostats.

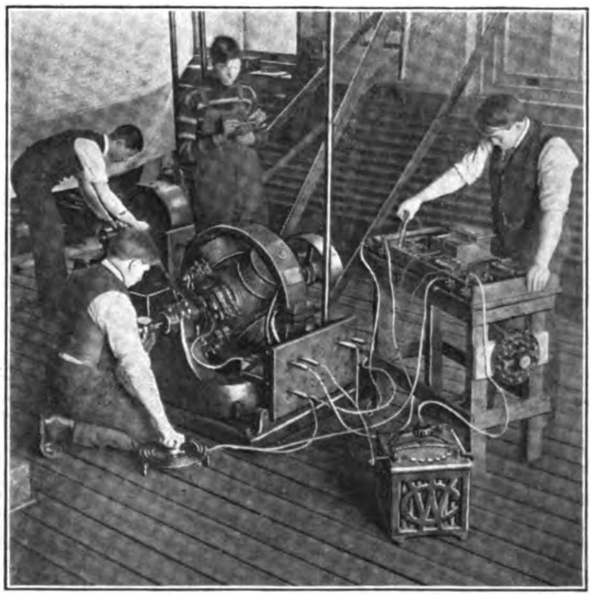

FIG. 1.—TESTING MULTIPOLAR MOTOR.

Fig. 1 shows students making a test of a multipolar machine running as a motor, and illustrates the application of the method under discussion. As a load the motor drives the dynamo in the background, which furnishes current to a lamp bank or water rheostats. A diagram of connections of the machine and the plugs and socket switchboard attached to it is shown in Fig. 2. In this diagram it will be noted that the leads of the series field winding terminate at a pair of sockets, as do the leads from the shunt field winding and the leads from the armature. Near the upper right-hand corner of the plug and socket switchboard are two sockets which connect to leads running to the main switchboard. These may be used to take current from or supply current to other apparatus. Near the lower right-hand corner of the slab are two sockets which are connected with a rheostat on the main switchboard (not shown). Obviously, it is possible by using the proper sockets and cables, with their connecting plugs, to connect the machine for shunt, compound, series or separate excitation, and instruments, resistance or rheostats may be connected in any desired circuit. The dotted lines indicate the plug and cable connections when the machine is to be tested as a compound-wound dynamo delivering current to the leads which extend to the main switchboard. The measuring instruments that would have to be included in some of the circuits, if the machine were actually under test, are not shown. A rheostat mounted permanently on a distant switchboard is connected to the lower right-hand pair of sockets for controlling the field current.

Fig. 3 is a view of another portion of the same laboratory. Not all of the machines shown are equipped according to the method described, but it is probable that in time all apparatus will be uniformly arranged in this respect. In the upper part of this engraving, on the gallery, is shown a plug and socket switchboard to which leads extend from the lamp bank shown behind it and from other parts of the laboratory. The wiring is so arranged that current generated in another part of the laboratory can, by the insertion of a few plugs, be brought to this switchboard. At this point it is available for use on the testing floor. Below the transformers, which are installed without cases, is shown another plug and socket switchboard. The different coils in the transformers are all connected by leads to sockets in the board beneath them, and any desired connections can be arranged by properly inserting the plugs of the connecting cables which have regular socket plugs on both ends. The transformer coils may be connected in series or in multiple, and by means of the same boards the transformers themselves may be connected in either series or multiple.

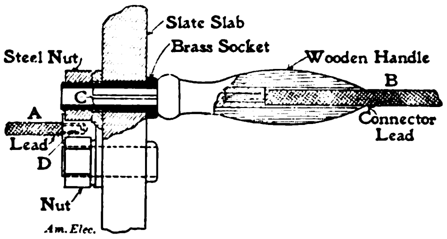

FIG. 4.—SECTIONAL VIEW OF PLUG.

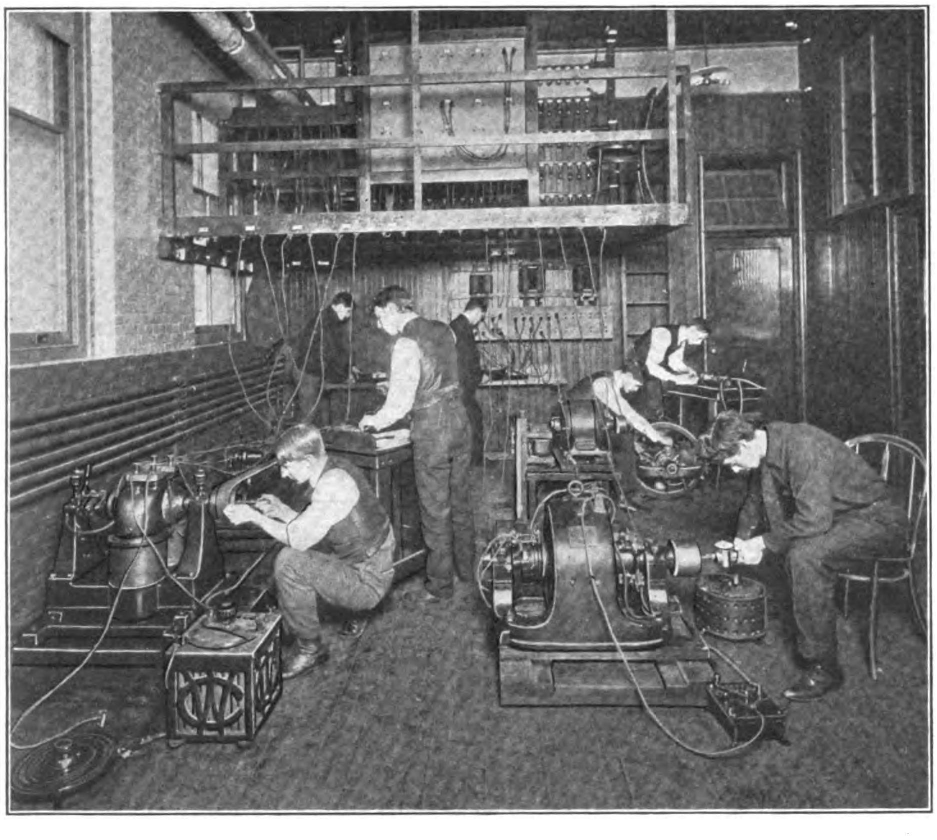

FIG. 3.—ELECTRICAL TESTING LABORATORY AT PRATT INSTITUTE.

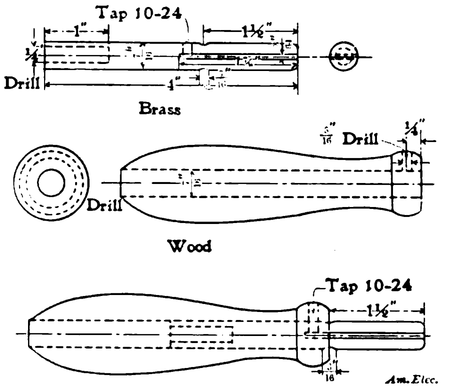
Fig. 4 shows a partial section of a standard plug inserted in a socket which is mounted in a slate slab, with the wire leading to the socket and the flexible cable leading from the plug. The wire marked *A* is soldered into the hole in the socket. To do this, the wire is first scraped and tinned, of course, and the socket casting is taken from the slate board and held in such a position that the hole *D*, prepared to receive the wire, is vertical. The casting is heated with a blow torch and the hole filled with solder. The wire is thrust in and the whole quickly cooled with a piece of soaking wet waste. The cable *B* is connected in the same manner to the plug rod. Dimensioned detail drawings of all the parts are shown in Figs. 5 and 6.



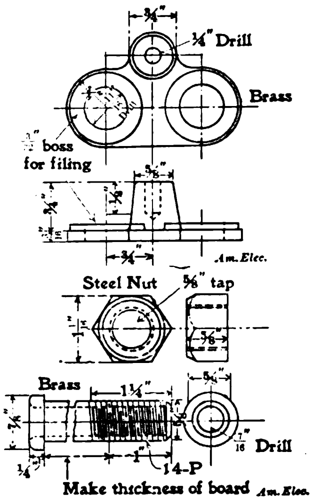


FIG. 5.—DETAILS OF PLUG AND SOCKET.—FIG. 6.

When it is desired to connect a voltmeter across two plugs, No. 18 flexible cord, having heavy insulation, may be used for voltmeter leads. The ends can be placed in the socket and the plug thrust in. There is enough elasticity in the plugs, because of the slot shown at *c* in Fig. 4, to allow this. The wires will be held firmly and will serve to hold the plugs in the sockets even more firmly.

At Pratt Institute the construction of the plugs and sockets and the smaller of the slate boards is made a part of the regular course of the electrical student; the machine work on the brass parts is done by students in the machine shop. The wooden handles are purchased, with brass ferules on them, as they can be obtained more economically in that way than by making them in the Institute wood shop. They are ordinary file handles and the 7/16-in. hole is bored through them in the shop. It will be noted that the plug proper is simply a piece of 7/16-in. brass rod slotted in one end, with a hole drilled in the other end and two small screw holes drilled in the slotted end. Flexible conductors, composed of many strands of fine wire, well insulated and braid covered, suitable for connecting the pairs of plugs, can be purchased from any of the electrical supply houses.

◆

SOME EFFICIENT METHODS OF MANAGING TELEPHONE INSPECTION DEPARTMENTS.

BY CHAS. H. COAR.

The expeditious correction of faulty line or instrument operations in a telephone exchange should be considered just as important as the acquisition of subscribers, and in consequence the inspection department should be regarded as a vital part of the exchange. However, in many exchanges equipped with up-to-date facilities one may find methods being practiced in the inspection department which are not at all in keeping with the remainder of the exchange.

Upon investigation not a great many exchanges will be found in which records of the individual lines are kept, from which it is possible to learn whether a line is absorbing or paying capital. Inefficient management of the inspection department is certain to cause a needless expenditure of funds sooner or later, to say nothing of the results that poor service effect in a community. But it is not the intention of the writer to discuss this effect or the apparatus directly involved in the testing; it is more to the point just now to sum up some of the qualifications necessary for a wire chief or chief inspector and also the inspectors or repairmen.

The chief inspector should be thoroughly acquainted with testing instruments and methods. He should understand telephone construction in all its branches. He should be well enough acquainted with details of construction, testing and repairing to enable him to judge a day's work. He should be able to explain the causes, reasons and remedies for faulty operations. He should be able to examine all applicants for positions under his jurisdiction in such a manner that only competent persons will be employed. He should be willing to inform his employes to the best of his ability on all matters which would tend to make their work easier or more intelligible to them.

Inspectors or repairmen may be divided into two classes. In the first class there would be such men as are capable of locating and repairing trouble whether it be in the outside construction, the inside construction or the instrument itself. In the second class there would be such persons as are capable of locating and repairing trouble occurring in the interior work or instrument. To be a competent workman in the first class, one should have had experience in construction work and the installation of instruments, while one experienced only in the installation of instruments should be eligible for the second class.

Many inspectors have a haphazard manner of doing their work; a great many of them cannot diagram or explain the circuits of a bell they have repaired for years; they do not realize the paramount importance of a so-called insignificant fuse, and they consequently dispense with fuses many times when it is easier to insert a piece of wire. It is frequently the case that wires are displaced from proper positions and left so by their unintelligent search for trouble or eagerness to finish a case. They hardly deem it necessary to solder a joint. These and other items of neglect cause in time a needless expenditure of capital. In many instances such conditions are due to the chief inspector, who has information given him with the intention that it be posted or otherwise given to the employes under his supervision in order that they may become more proficient. This is very noticeable when blueprints are made for the inspection department, which should be hung on the walls or placed where they would be easily accessible to the employes, but which on the contrary are often placed under lock and key for the benefit of a favored few.

Every company having an inspection department will find it very much to its interest to adopt the issuance of bulletins, or other methods, by which concise information can from time to time be furnished to the employes concerning the apparatus, circuits, etc., they have to deal with. Text books, of course, cover general rules and principles very well, but they do not contain much detailed information regarding the apparatus involved in any particular system, therefore the provision of such information would be very beneficial; it not only enables the men to do better work but it also creates a feeling of satisfaction and interest in their work. If information of this description is furnished to the employes it should become part of their duty to acquaint themselves with it.

A very successful method of obtaining good results from inspectors consists of establishing districts in the exchange territory and assigning a district to each man; in this manner an employe can be held more strictly accountable for the work he is doing, and furthermore, the inspector is able to accomplish more in the same time from the fact that he will become familiar with the conditions, locations and needs of the lines in his territory more than he would if he had no special district but was assigned a case here or there as the trouble required.

By arranging the exchange territory in this manner, men having the ability to repair and maintain the lines in districts containing trees, etc., can be assigned to districts where such conditions exist, and men having ability to repair and maintain building wires in business districts can be assigned to such districts. Results are obtained in this manner which are otherwise impossible. For example, if an inspector whose time has been devoted mostly to residence districts be sent to repair a line in a business district, after getting his line location he is usually lost, as he needs a step-ladder, he requires the services of the janitor, or he wishes to get on the roof, and numerous other things all of which take extra time for one not acquainted; the same sort of condition exists in case an inspector from the business district is sent to a residence district where he has trees, etc., to contend with.

In order to facilitate the repairing of telephone lines, complete position records should be maintained of each individual line, so that any line information, such as its pole position, cable conductor, class of service, and address or addresses of the subscribers, can be readily obtained.

A cable record should have space allotted for the following items:

1. Cable number or letter.
2. Route of cable (underground or aerial).
3. Numbers of the terminal poles or boxes the cable feeds.
4. Designation of such poles or boxes as are in multiple with each other.
5. Drop number of line; what class of service the line is, and the number of the cable conductors, preferably arranged opposite each other.

A card record of this description may be made to provide space for one, two or four hundred conductors, and it should be constructed of such material as will allow a considerable number of erasures without becoming unfit; records of this description are usually made in lead pencil on account of the many necessary changes occurring in them, but this is a poor policy.

Pole diagrams or records should conform with the kind of pole they represent, either a distributing pole having circular frames from which the different lines radiate, or the usual lead pole, and space should be allotted for the following items:

1. Number or letter of pole.
2. Location of pole.
3. Number of cable feeding pole.
4. Number of cable conductors.
5. Pin locations; drop number on these locations and class of service of these drops or lines.

It is customary to diagram lead poles facing the direction the lead runs by starting with the left end pin on the top arm and counting to the right on each arm. Whatever method is used, the inspectors should be thoroughly acquainted with it.

The lines records used in the inspection department are preferably in the form of index cards arranged in numerical sequence, with space provided on each card for the following items:

1. Drop number.
2. Pole number.
3. Arm......... Pin.........
4. Number of cable.
5. Number of the cable conductors.
6. Class of service.
7. Address and calls of subscriber.

A card 3½ ins. x 5 ins. will contain all these items and still have available space for five subscribers' names and addresses.

Having described a card system for keeping records of the lines, it will possibly be in order to outline a method of keeping record of the trouble occurring on these lines, and as it is customary in the larger exchanges for a clerk to receive the trouble complaints, after which they are tested and assigned to the inspectors if necessary, a check or slip upon which the clerk may record a report as he receives it will be useful. A report check having space provided for the following items is convenient:

1. Drop number.
2. Date.
3. Pole, arm and pin.
4. Class of service.
5. Time reported.
6. Reported by.
7. Tested.
8. Addresses.
9. Time assigned.
10. Time O.K.
11. Trouble found.
12. Inspector's name.

By ruling a blank sheet of paper in divisions in such a way that a division is provided for each 100 lines in the exchanges, one can tell at a glance if any line is reported out of order. For instance, if subscriber's line No. 1214 was out of order, 14 would be put in the 1200 division on the check sheet. This is a very convenient way of knowing if a line is reported or not, and as such information is often requested by a subscriber or a company official this sheet should not be neglected.

There remains one more check form, namely, the slip which is given the inspector, and in connection with this check it might be well to mention that the slips should be made of good paper, as they are handled or carried about considerably.

The inspector's slip should have space provided on its face for the following data:

1. Drop number.
2. Date.
3. Pole, arm and pin.
4. Class of service.
5. Tested.
6. Addresses.
7. Time reported.
8. Time started.
9. Time O. K.
10. Signature.

On the back the following items should be noted:

1. Trouble found.
2. Remarks.

Assuming that the exchange territory is divided into districts and that each district inspector has a pigeon-hole at the clerk's desk in which the clerk places the line check reports, it will be advantageous to follow a report throughout its customary course.

(*a*) Trouble is received by the clerk, who records it on a report check, noting the time and by whom it was reported.

(*b*) The person doing the testing takes the report check and tests the line, recording the results on the check.

(*c*) If the line is in trouble, a clerk records the line positions, addresses, etc., in the spaces provided and assigns the check to the pigeon-hole representing the district the line is in.

(*d*) The line is given an inspector who fills out the inspection slip with the necessary data.

(*e*) The inspector clears and reports the line O.K. to the trouble clerk, stating what the trouble was.

(*f*) The clerk places the finished report in a pigeon-hole provided for it.

When the inspectors return to the office, the inspector's slips may be compared with the report checks if it be deemed necessary, after which the slips may be placed in bundles suitably marked for reference.

The information contained on the finished report checks can then be placed in a suitable record book, or the report checks can be assigned to pigeon-holes which are intended to hold the finished reports of a designated number of lines. At the end of each month the individual cases of any line may be bound together and stored away for reference. By arranging the check sheets in daily rotation and filing them, one can readily ascertain by referring to them at what date any particular line was out of order, after which any other desired information may be obtained from the record book or report checks.

As the maintenance of toll lines and stations is usually conducted from the inspector's office, it might be well to outline a trouble slip which will be useful in recording the necessary data regarding toll line trouble. A report slip having a similar form to the one outlined herein will have space provided for the principal items mentioned in toll line repairs as follows:

The inspectors should be instructed to note under "Remarks" on the trouble slips all faulty conditions of the lines in their respective districts that they are unable to repair alone, in order that such repairs as require a crew may be made without delay. During stormy weather lines having defective insulation may be traced and the defective spots located, after which they should be repaired at the first opportunity.

Slack wire, loose pins and brackets, twisted arms, insulators off, wires not tied, joints not soldered and all other such conditions which not only present an unsightly apparance but make trouble should be promptly repaired. The inspector's grip should contain with the other accessories some polish and a rag for cleaning dirty instruments, as there is nothing more discouraging to a prospective subscriber than a dirty or grimy instrument. Inspectors should also have impressed upon their minds the necessity of looking for loose contacts, wiping the rust collection off the receiver magnets and diaphragms, displacing bent diaphragms, trying the transmitter and receiver cords for cut outs, retacking loose wire, and such other things as seem to need attention whenever one is sent to repair a telephone; such work may prevent a faulty operation at some future time and consequently a subscriber's complaint. During the time the inspectors have no reported trouble to repair they can inspect the wires and telephones in their districts, but while thus employed they should keep in touch with the office in order to receive any trouble orders.

Trouble occurring in the cables or cable terminals can best be remedied by men employed in the cable department, and for this reason the inspectors should not go further than the line pin or cable terminal if the trouble is towards the office. After such trouble has been corrected by the cable department, the usual course can be followed. When an inspector has a line assigned to him on which there is trouble, his report should state explicitly whether he cleared the trouble or whether it disappeared of its own accord, in order that the proper precautions may be taken for its location. The writer once employed an inspector to whom he assigned a case of trouble which had bothered the subscriber off and on with a scraping noise during conversation. As it seemed impossible to apply a test to this line when the trouble was occurring, the inspector had orders to inspect the line and instrument thoroughly, and after spending nearly half a day he reported back that he had found a piece of hay baling wire swinging in contact with one side of the line and a guy wire. Believing that this trouble had been cleared, it was recorded, but the next day it was faulty again. Another inspector was assigned to the case and he found and cleared the trouble, which was in the lightning arrester. Learning this, a clear line was assigned the first inspector, who was told that the line had a similar case of trouble. After another half day spent in rest or otherwise, the bale-wire story came in again. But it was his last report with that company, and the general effect this occurrence produced among the men was good.

In conclusion, the writer wishes to impress upon the reader's mind the practicability of systematizing the work of the inspection department, and also state that the adoption of some system similar to the one outlined herein will produce good results, as has been demonstrated in exchanges where no particular pains had been taken in the management of this important department.

PELTON WATER-WHEEL COMPANY'S TESTING ROOM.

BY GEO. J. HENRY, JR.

In designing buckets for tangential water-wheels, there are so many elements to be taken into consideration none of which can be predetermined with any degree of accuracy by any ordinary mathematical process, and all of which are so entirely interdependent that a wrong assumption in regard to any of them produces the most erratic results. Investigators applying the rule of common sense only to bucket shapes have usually ignored some of the most important considerations, and as an operating water-wheel from which any measurements are taken is made up of a number of different parts and any measurements that may be taken from it involve a number of other losses than those of the buckets only, some more reliable method of design has become necessary.

It has been the policy of the Pelton Water-Wheel Company, of San Francisco, always to design a water-wheel for the particular conditions under which it is to operate, invariably making such changes in the buckets as well as all of the other parts of the wheel it builds as will bring about a maximum efficiency. The losses going to make up the total loss in any given water-wheel installation are many in number, and the elimination or reduction of any part results in some improvement. The necessity for the accurate determination of bucket losses as separated from those of windage, journal friction, nozzle and stream losses, made it necessary to devise apparatus of an entirely different nature from anything heretofore used for this purpose.

The use of the prony brake on small model wheels included losses of the windage and journal friction and of the nozzle and stream, all of which were so large compared to the bucket losses in a well-designed wheel that very little reliability could be placed upon it. The following method was therefore devised by the writer for eliminating these losses. The apparatus, which is illustrated in Fig. 1, is installed in a room especially fitted up for the purpose in the Pelton Water-wheel Company's factory at San Francisco.

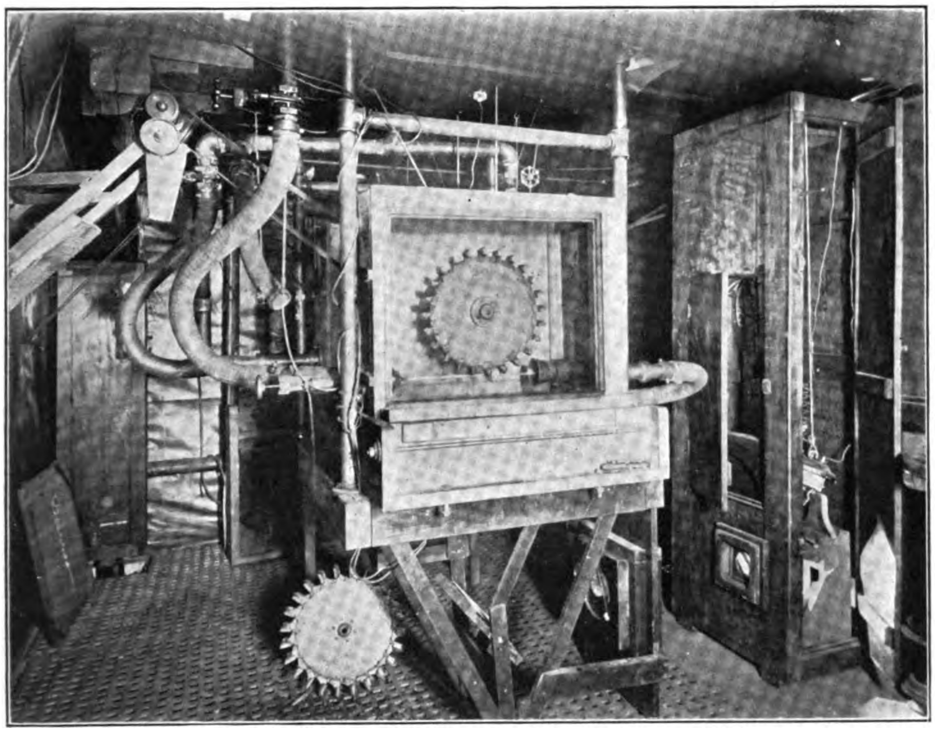

FIG. 1.—PELTON WATER-WHEEL COMPANY'S TESTING ROOM.

A constant head of water of about 50 feet is obtained by a pump delivering an excessive amount of water to a tank on the roof. This tank is provided with a separate overflow pipe, and some water is constantly overflowing. Two separate pipe lines are taken from this tank to the wheels to be tested, one pipe being used to supply each wheel. The general arrangement is shown in Fig. 2. It is obvious that by using a throttling device in the pipe, the head or water pressure at the nozzle outlet may be varied from zero up to the maximum obtainable from the tank, less the friction losses, and maintained absolutely constant. A suitable shaft carried in ball bearings and fitted on one end with a driving wheel is arranged to be rotated by a stream of water from one of the pipes; mounted on the opposite end of the same shaft, in its casing and exactly in position to receive the water properly, is a second wheel fitted with the buckets to be tested. This second wheel and casing are shown in the foreground of Fig. 1. The model wheels are made in any size up to 18 inches in diameter.

Now, by driving the first wheel at any speed at which a measurement is to be taken, and adjusting the water from the first nozzle so as to just carry the wheel at this speed, the power to overcome all of the windage and journal friction of the second wheel is supplied by the first wheel. A prony brake nicely balanced on knife edges is mounted in position on the shaft between the two wheels, a jet of water from the second pipe line is turned on the second wheel, and the prony brake is adjusted until the shaft is running at the same speed as before; the brake is then absorbing the exact amount of power developed by the buckets, independent of the journal friction and windage. It is obvious that measurements may thus be taken at any speed desired and a series of measurements made that will give the efficiency curve for any shape of bucket desired, including nozzle losses.

To separate the nozzle losses, it is necessary to obtain the coefficient of discharge from the nozzle. In the particular apparatus built by the writer and illustrated herewith, each of the nozzles is provided with a mercury column pressure gauge on which readings may be obtained with great accuracy. The pressure is taken from a series of holes 1-16 inch in diameter, drilled completely around the nozzle body at a point just before the contraction of the stream begins, the axes of these holes being normal to the stream axis. These holes open into an annular chamber formed about the outside of the nozzle and connected to the above mentioned mercury pressure gauge. A pendulum, beating seconds accurately and provided with the necessary electrical contacts, is arranged in connection with a suitable timing apparatus to admit the stream issuing from any nozzle tip for an exact number of seconds (independent of the personal error), this stream being caught in a suitable receptacle and weighed. The diameter of the nozzle having previously been calipered exactly, one can readily determine the coefficient of discharge for the nozzle and make the necessary correction in the wheel efficiency curve above mentioned. As a check on the coefficient of discharge, a calibrated sump tank is used in which the discharge from any given nozzle may be caught for a long period of time.

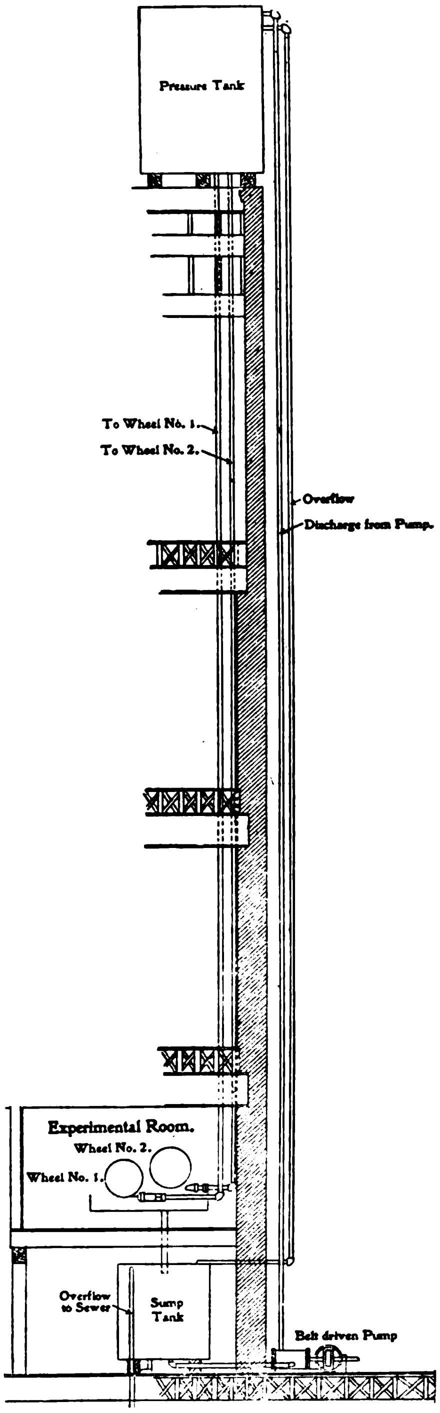

FIG. 2.—ARRANGEMENT OF APPARATUS.

This method of investigation, while giving the actual results obtained, was not sufficiently satisfactory in indicating how corrections or improvements in bucket design could be made, and it was therefore desired to introduce some method to discover the cause of certain irregularities in the bucket-efficiency curve. The measurement of the impulse pressure against the bucket when the wheel is stationary did not give any idea of what would actually occur when the wheel was rotating, and the high velocity at which it was necessary to rotate the wheel in order to approximate operating conditions made it impossible to determine visually what was taking place on the individual bucket surface.

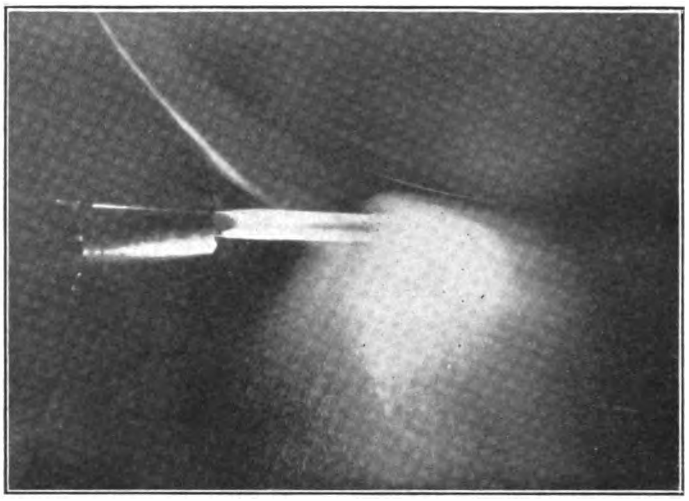

FIG. 3.—WATER DISCHARGE FROM BUCKETS.

A special shutter was therefore arranged, rotating in front of an arc lamp and admitting from the arc flashes of light in synchronism with the passage of the buckets. In other words, the entire rotating wheel is arranged to be illuminated by a flash from the arc lamp at the instant of time that each bucket passed a given point. The result of this to the eye is a stationary image of the wheel with the water being removed on traversing and discharged from the bucket surface exactly as it occurs in practice. It also eliminates from the vision everything that occurs on the bucket at any other instant of time. By displacing the position of the image and slightly moving the lamp, the condition of water impulse flow and discharge may be examined for a consecutive series of positions, and any crowding of water over any portion of the bucket surface, or any spattering that might occur due to the wrong angle of the entering lip, or any incorrect discharge angle, or discharge against the back of the bucket next following, can readily be observed and the changes in bucket surface to make the necessary correction deduced. Not only are the causes of known losses readily discovered by this means, but methods of improvements in bucket shapes become apparent by this method of investigation. In Fig. 1 the arc lamp and shutter case are shown at the right, and the 45-degree mirror by which the light is thrown on the buckets through the glass bottom of the wheel case may be noticed below the wheel.

This apparatus is in constant use by the Pelton Water-wheel Company for the determination of bucket shapes, and has resulted in obtaining much more reliable constants for use in the design of water-wheels than can be obtained by any other method thus far made known. It is adapted for use with any type of nozzle, and furthermore, the nozzle may be adjusted vertically. When the photograph of Fig. 1 was taken, a needle nozzle was used.

Some interesting photographs have been taken by this apparatus which show the effect of the stream on the buckets. Fig. 3, for example, was taken with the wheel revolving and shows the water being discharged from the buckets at almost zero velocity. Fig. 4 is an instantaneous view taken of the test wheel with the aid of the shutter when the wheel was running at high efficiency. It shows the discharge from the sides of the buckets to be parallel with the entering jet. The photograph also indicates that the front of the Pelton bucket enters the stream without shock or disturbance of any kind and that all of the energy is removed from the water by the shape of bucket being tested.

By the aid of the test wheels, the company has been able to design its buckets and wheels so as to give the highest efficiency, and the efficiency as experimentally determined in the test room, it is said, comes within 1 per cent. of the operating efficiency of the completed wheel after installation. The test apparatus is patented by the writer.

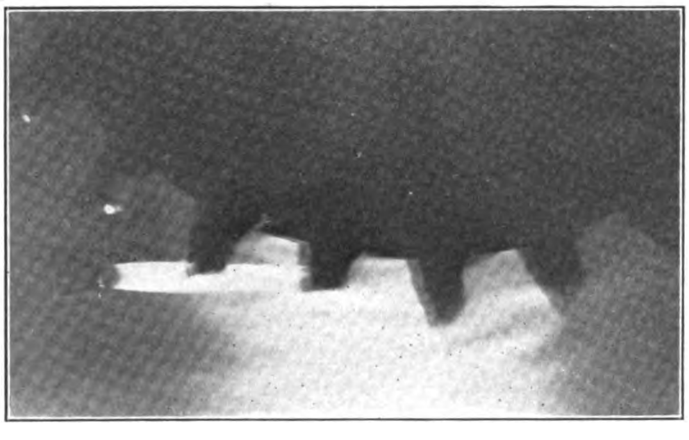

FIG. 4.—INSTANTANEOUS VIEW OF TEST WHEEL.

THE WIRING OF EXPOSED STEEL FRAME BUILDINGS.

BY ARTHUR B. WEEKS.

The accompanying sketches and the following notes as to ways in which wires are secured to steel beams and girders describe a favorite method of construction. In the wiring of steel buildings of the mill or machine-shop type, the wires are strung high up among the steel work; often porcelain knobs are merely tied to girders with soft iron wire, and the insulated line wires secured to them throughout the building. It may be that one circuit is for arc and another for incandescent lamps, with still another for motors. Fig. 1 shows a method of securing large conductors. Large knobs or cleats can be fastened directly to the top timber, which is virtually a cross-arm, or malleable iron or oak pins can be used, with screw glass insulators. Smaller wires can also be tied to the timber, if required. The cross-arm is selected according to the needed strength. The bolts for fastening may be either carriage or machine bolts and need not be larger than ½ inch.

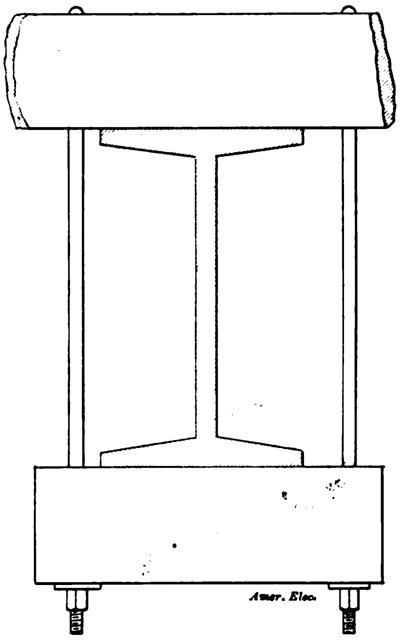

FIG. 1.

For similar work among smaller girders, the construction shown in Fig. 2 does very nicely. Should this method be followed for incandescent lighting, and individual cut-outs be used, they can be located on the cross-arm and the lamp cord dropped through a porcelain tube at the end of the arm. A better plan than using individual fused rosettes away up among the rafters is to control each circuit by a switch, and fuse it. In this case the wire for the drop lights must be of the same size as for the remain-

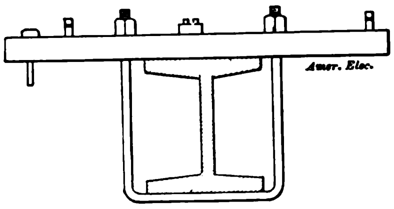

FIG. 2.

der of the circuit, which is ordinarily No. 14 B. & S.; if in a dry room and there is considerable drop, the hanging wires should be twisted. Cleats or porcelain insulators may be used to secure the horizontal wires, but the insulators are generally preferred in such cases. Two tubes will be required with this method, although a cleat could be used at the edge and side of the cross-arm to drop from.

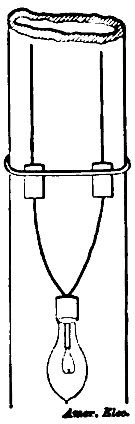

FIG. 3.

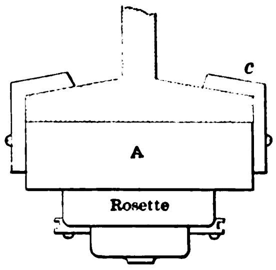

FIG. 4.

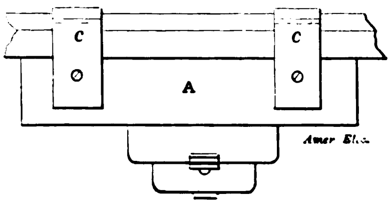

FIG. 5.

Should there be considerable moisture in the room, from leaky roofs, steam or damaged pipes, a method similar to that indicated in Fig. 3 is convenient, especially if the drop light is to light a lubricator or gauge. The insulators are tied by iron wire to the pipe, and the wires are let down through the insulators. Not enough care is used ordinarily in running light and power wires through damp rooms, especially in the vicinity of moving cables, tie rods, etc. Sometimes slack gets into wires which are run too close to elevator cables, and possibly the dampness of the place assists in the final open circuit. This open circuit is not always discovered by mere inspection for the insulation may remain nearly enough intact to retain the wires in place; so if the circuit is a long one, the best method of locating the trouble is to use a test lamp across the circuit until the break is found. Sometimes also weather-proof wire is used in localities so damp and so impregnated with steam that the insulating qualities of the best weather-proof covering will eventually be destroyed. For such places a good rubber core wire should always be used. Too often wires are run in places which are in the direct path of oilers, inspectors and others, with the result that they are soon pulled down upon the iron work, or torn entirely from their supports.

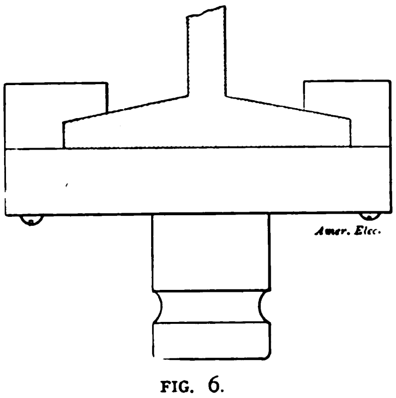

FIG. 6.

When cutting the cross-arms, they must be made long enough so that the wires will clear all tie rods, and the supports must be located close enough together to prevent sagging; if the spans are too long the wires may sag into contact with the iron work between the supports. By the proper spacing of the wires, many porcelain tubes can be eliminated. Some buildings, such as blast furnaces, for example, let in the rain or snow so that the liability to grounds or short-circuits always exists if the wiring is not properly done. Circuits in some such buildings have been found fused on one "leg" only. Common sense is a good thing to use in these cases, for not even the Underwriters' Rules can be a guide in every case. The National Code says: "Switches must not be single-pole when the circuits which they control supply devices which require over 660 watts of energy." This is all right in many cases, but what wireman has not found it advisable in places to use a double-pole switch for less than 600 watts?

Figs. 4 and 5 show a method of supporting lighting circuits along the under surfaces of I-beams. The wood support, *A*, is cut the desired length to take the rosette and cleat, and of a width the same as the face of the beam. The iron clamps, *c*, *c*, are 1 inch wide and ⅛ inch thick. They can be bent cold, and the wood support is held by them through wood screws. No screws are required elsewhere, of course. This plan is used throughout many factories of skeleton steel construction for supporting large power wires. For example, if the wires are 300,000 c. m. and the system is 440-volt, two-phase, the wood supports would be cut the width of the I-beam, and not only long enough for present needs but with allowance also for future circuits; the clamping irons would be 1 in. x ¼ in. with No. 12 wood screws, 1½ ins long. The porcelain single wire cleats should be spaced so that the wires are 4 inches apart. The I-beams will probably be about twelve feet apart, so that when properly pulled up, there will be no appreciable sag in the wires between supports.

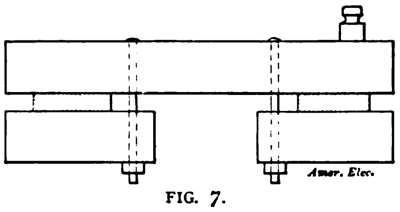

FIG. 7.

The method shown in Fig. 6 is sometimes used, but when it is used greater conveniences are usually at hand for cutting the wood to the proper bevel than are required for getting out the iron clamps. Fig. 7 shows a plan which is best employed in certain locations. The porcelain insulators are fastened in the usual way on top of the cross-arm, which is ordinarily 2 ins. x 4 ins. in cross-section.

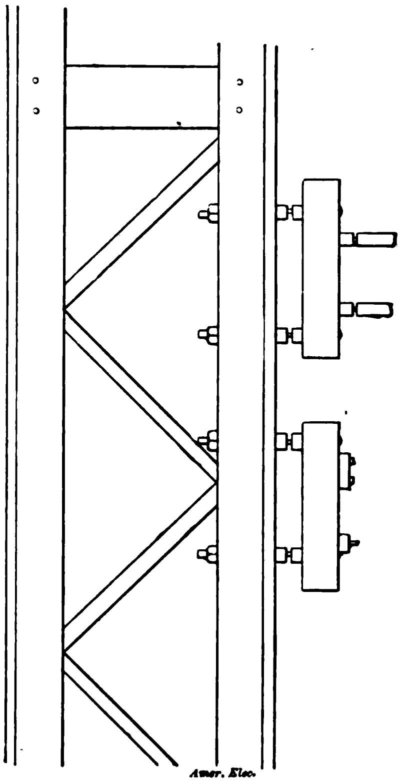

FIG. 8.

Where the wires are to be run along the side of a steel building, the arrangement shown in Fig. 8 is very good. The bolts pass through the space between the angle irons. If the building is not subject to dampness, there is no necessity for insulators between the wooden supports and the steel work. One of the supports may carry the fuse-block and switch, and the other the porcelain insulators for the line-wires. If there is more than ordinary heat in the vicinity of this line, slow-burning weather-proof wire should be used.

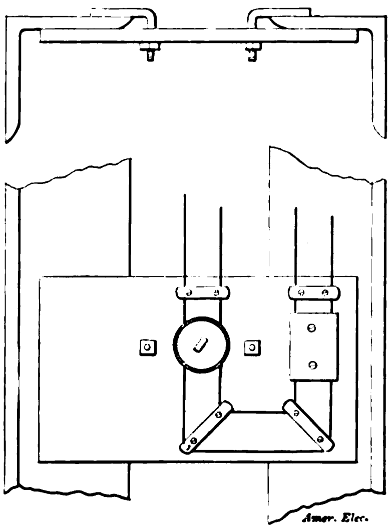

FIG. 9.

If it is desired to place a switch and cut-out for a lamp circuit within reach of the floor in a high steel building, a board can be fastened as shown in Fig. 9. Two ⅜-in. bolts are bent as shown in the upper sketch, and holes to take the bolts with a driving fit are drilled through the board. The wires may be fastened to insulators between the board and their upper connections in the way which best suits the case. Often four porcelain insulators can be tied separately to an iron brace and spaced properly side by side so that the wires can be run through the insulators. This is a quicker way than any others, and the effect is very neat.

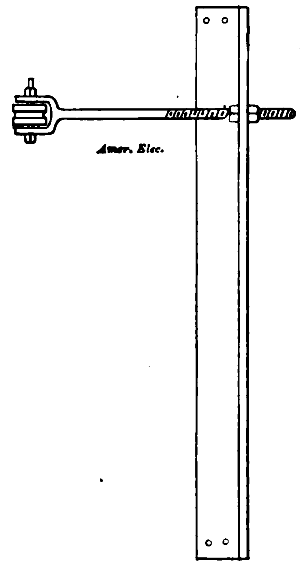

FIG. 10.

In some places, in channel iron columns, for example, blocks of wood can be driven in place with a hammer, so that no other mounting is necessary for a switch and fuse-block.

Fig. 10 shows one method of taking up slack in the bare trolley wires of a traveling crane. Any blacksmith can make the bolts, and the wire is tied to a porcelain insulator of the ordinary type shown. Turn-buckles are frequently used for this purpose and Brooklyn strain insulators are also employed. Usually four to six of these trolley wires are secured to the same angle iron, properly spaced, of course. There is one disadvantage when bolts are used as shown in Fig. 10 if they are exposed, as they frequently are, to the weather; after long standing the bolt becomes so rusty that it will twist off before the nuts move.

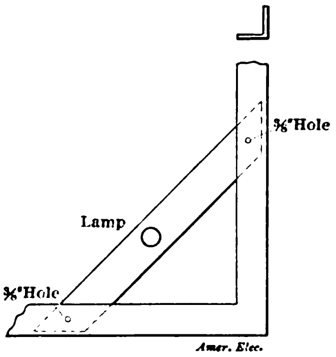

FIG. 11.

Fig. 11 shows a method of mounting an incandescent lamp to light the top of a blast furnace. A hand punch was used to make the ⅜-in. holes, and a piece of 2-in. x 4-in. scantling was placed across the corner as shown. A Newguard lamp was used and mounted on the scantling by means of a ½-in. crow-foot. Circular loom was used through the holes drilled in the scantling. The lamp had the customary rubber washes between the outer globe and its base to exclude moisture. There are times when no lamps or wires can withstand the flame and heat in such a location, so it is only a case of putting them up again should they be burned away. The wires are brought up to the top of the furnace along the most accessible route, and the one least liable to excessive heat. Porcelain insulators are tied to the steel work and the light wires are fastened to them, as already mentioned.

Sometimes it is necessary to punch holes through the corrugated sides of steel buildings to get a tie for insulators. In this manner, wires can be carried from one building to another without passing through intermediate buildings at all. In going from building to building in this manner, precautions should be taken against winter weather by having all wires very substantial, so that they can withstand the weight of accumulated and falling ice.

Lessons in Practical Electricity

ALTERNATING-CURRENT CIRCUITS.

The two parallel wires of alternating-current constant-potential circuits not only constitute a condenser (of very small capacity) but are of an inductive character, like the coil of an electromagnet, but in much smaller degree. This is due to the fact that the magnetic lines of force which encircle each wire when a current is passing (see Fig. 1) expand and collapse from and toward the center of the wire as the rapidly alternating current rises from zero to maximum and falls to zero again; in thus expanding and collapsing, the magnetic lines "cut" the conductor and induce an e.m.f. in it. If the wires of a given two-wire circuit are very close together, the magnetic circles produced by each wire encircle both of the wires and neutralize each other; if the distance between the two wires is a few inches, some of the magnetic lines from each wire encircle the other wire, as indicated in Fig. 2, and the inductive effect is partially neutralized, but not entirely. Therefore, the farther apart the two wires are located, the worse will be the inductive effect.

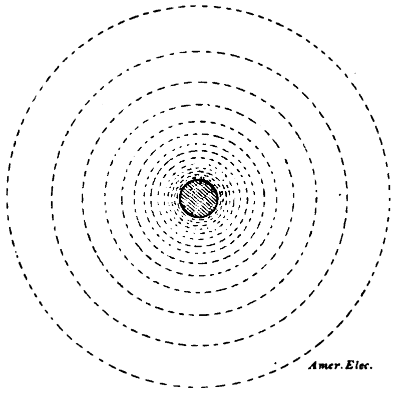

FIG. 1.

The e.m.f. thus induced in the line-wires opposes the e.m.f. which is applied to the circuit to force current through it, but not directly. The relation between the e.m.f. which overcomes the resistance of the wires and the inductive or reactive e.m.f. induced in them is exactly the same as that between two mechanical forces applied to a common object from directions at right angles to each other; the resultant of these two e.m.f.'s is the e.m.f. actually applied to the circuit. Fig. 3 illustrates this point. The horizontal line represents the e.m.f. expended in overcoming the ordinary resistance of the circuit wires; the vertical line indicates the reactive e.m.f. induced in the wires by the magnetic flux, as just explained. If these two lines are drawn to scale so that their relative lengths are the same as the relative volts that they represent, the diagonal line will represent, to the same scale, the volts that must be applied to the circuit in order to force through a current of such value as to cause the line resistance to use up the volts indicated by the horizontal line. For example, if the current is 10 amperes and the resistance of the two wires is two ohms, the "resistance e.m.f." or e.m.f. required to overcome the line resistance, will be 20 volts. Then if the reactive e.m.f. induced in the wires is 15 volts, the impressed e.m.f. necessary to force 10 amperes through the line will be

$$E_z = \sqrt{E_r^2 + E_x^2} = 25 \text{ volts.}$$

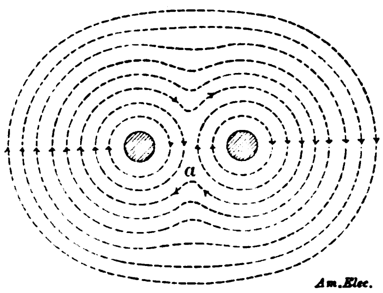

FIG. 2.

The circuit being inductive, the current in it will lag behind the applied e.m.f. in rising and falling, as explained in a previous lesson.

If the circuit supplies a group of incandescent lamps (which are non-inductive, of course) both the load and the circuit wires must be considered in ascertaining how much applied e.m.f. will be needed, but the total e.m.f. will not be the simple sum of the volts at the lamps and the impedance volts in the line. The volts required by the lamps must be added to the volts required by the resistance of the line, and a new triangle of forces constructed. Thus, if

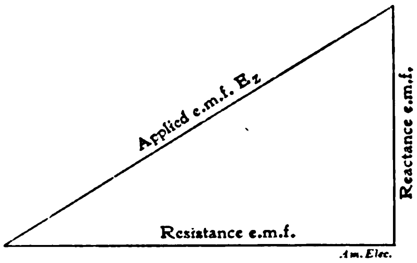

FIG. 3.

there are 20 lamps in the group, requiring 110 volts, the lamp current will be practically 10 amperes and the resistance volts of the line will be 20, as before; the horizontal line of the diagram, therefore, would be drawn to represent 110 + 20 = 130 volts.

TABLE I.

Power Factors and Inductance Factors.

Power Factor p	Inductance Factor q	Power Factor p	Inductance Factor q
.70	.7142	.85	.5267
.71	.7042	.86	.5103
.72	.6940	.87	.4930
.73	.6835	.88	.4750
.74	.6726	.89	.4560
.75	.6614	.90	.4360
.76	.6500	.91	.4147
.77	.6380	.92	.3920
.78	.6258	.93	.3675
.79	.6131	.94	.3410
.80	.6000	.95	.3123
.81	.5864	.96	.2800
.82	.5724	.97	.2430
.83	.5578	.98	.1990
.84	.5426	.99	.1410

The vertical line would remain as before, and the resultant diagonal would be as shown in Fig. 4; this would indicate an applied e.m.f. of

$$E_z = \sqrt{(E + E_r)^2 + E_x^2} = 130.86 \text{ volts.}$$

When the load is inductive, its resistance e.m.f. must be added to that of the line-wires and its reactive e.m.f. added to that of the wires; the sums of these will be the resistance e.m.f. and the reactive e.m.f. of the system as a whole, and the required applied e.m.f. is obtained from these two, as in the cases just explained.

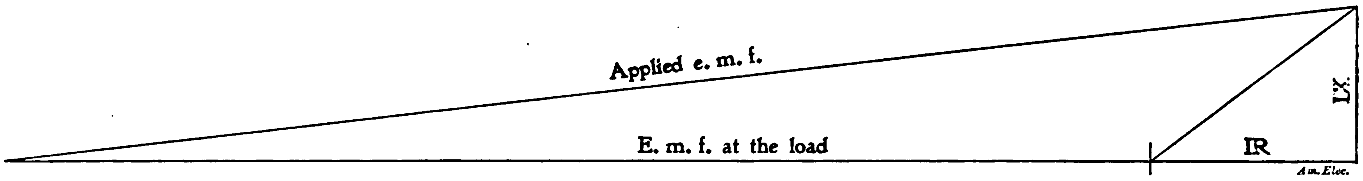

FIG. 4.

The resistance e.m.f. of an inductive piece of apparatus is ascertained by multiplying its rated e.m.f. by its power factor (see last month's Lesson), which is always specified by the manufacturer of the apparatus. The reactive e.m.f. is obtained by multiplying the rated e.m.f. by the "inductance factor" of the apparatus; the inductance factor depends on the power factor, being the sine of the angle of which the power factor is the cosine. (The student should take pains to avoid any notion of angles in currents and e.m.f.'s; angular functions are used in alternating-current mathematics as a matter of convenience, but there are no angles between actual e.m.f.'s and currents.) Table I herewith gives a list of inductance factors corresponding to different power factors.

The "resistance e.m.f." of a line is merely the resistance in ohms multiplied by the current that flows; the reactive e.m.f. is obtained by multiplying the line reactance by the current, but the reactance is not easily ascertained. Table II gives the inductive reactance of two parallel wires each 1000 feet long, at different distances apart and at the two frequencies mostly used in this country.*

From the foregoing, it follows that the e.m.f. required at the "starting end" of a two-wire line supplying a given load at the other end is

TABLE II.—Reactance of two parallel Copper Wires each 1000 Feet Long.

Wire Sizes.	Distance apart of the wires 3 ins.	6 ins.	9 ins.	12 ins.	18 ins.	
00	.1402	.1720	.1907	.2039	.2226	At 60 cycles.

8	.4182	.4889	.5304	.5598	.6012	
10	.4418	.5127	.5540	.5834	.6249	
12	.4655	.5363	.5777	.6071	.6485	

$$E = \sqrt{(E p + I R)^2 + (E q + I X_l)^2},$$

in which E is the e.m.f. at the load; p, its power factor; q, its inductance factor; I, the current it requires; R, the resistance of the circuit wires, and Xl, the reactance of the wires. The effective "drop" in the line wires is the difference between the applied e.m.f., Ez, and the e.m.f. E, at the load.

The capacity or condensance of a short line is so small as to be practically negligible, but on long lines it becomes a serious feature. Since the two wires act as the plates of a condenser, the farther apart they are, the less will be the condensance of the line; but since the inductance of the line increases as the distance between the wires is increased, it is not practicable to bring the condensance down to a negligible point by merely separating the line wires to great distances. It sometimes occurs that the condensive or capacity reactance (see last month's Lesson) equals the inductive reactance of the line; when this is true, the line is said to be in a condition of "resonance," and in that condition the current follows Ohm's law and the "drop" in the line is simply the product of line resistance and current.

Letters on Practical Subjects

Some Things We Need.

To the Editor, American Electrician:

Manufacturers of electrical supplies are generally quick to see and even to anticipate the need for various devices used by electrical contractors. There seems to be one very great deficiency, however, which we feel especially in Chicago, and I think likely has been felt elsewhere. This is in regard to ceiling rosettes for drop cords. The rules of the Electrical Inspection Department of Chicago, which are the same as the National Code, with a few additions, require drop cords to be soldered directly to the wires at a ceiling outlet. When the electrical contractor has to put in a drop cord with concealed work in this city, he finds that he must adopt some make-shift because of the lack of any porcelain ceiling rosette adapted to enclose a soldered joint. What is known as a self-tying seal button is all right for open work, but if used on concealed work, the taped joints must be left exposed, which makes the job so unsightly that it is not allowable in ordinary residence or office wiring. An ordinary fusible porcelain rosette can be used by breaking out the partition on the base and tucking away the soldered joint in the small space within the rosette. This, however, is a make-shift, as the wires are crowded and the rosette was never intended to take a soldered joint. Another way out of the difficulty which has sometimes been used is to put a keyless socket or receptacle on the ceiling and to attach the drop cord to it by means of an extension plug. This, however, is purely a make-shift and it is difficult to see why, if a drop cord is to be permitted on an extension plug, with binding posts on the plug, it is not equally permissible to connect the drop cord into the binding posts of a fuseless rosette in the first place and do away with the plug and socket. The one really workman-like solution of the question seems to be to purchase a small fixture canopy with a wooden ceiling block which will just fit the canopy and to which the edge of the canopy can be fastened by screws. The canopy allows plenty of room to conceal a soldered joint between the cord and wire, and the wooden block insulates the whole thing from the ceiling. But why should we be obliged to do this for lack of the right kind of porcelain rosette? Why cannot manufacturers make a two-piece porcelain rosette without binding screws and with plenty of room to conceal the soldered joint? Such a rosette should consist of two pieces, a simple flat disc of porcelain for a base, and a cap with room in it for a joint and a knot in the cord. The rosette could be fastened to the ceiling by a pair of wood screws going through both pieces. This would make a simple, neat and substantial job. There may be some such rosette on the market somewhere, but if there is, it is not in evidence in manufacturers' catalogues or in Chicago supply stores, where of all places it should be kept on sale.

---

* The formula is $2 \pi f L = X$; and $L = 1400 \times$ *length in feet* $\times (0.10857 + \log \frac{d}{r}) \div 10{,}000{,}000{,}000$; d = distance apart; r = radius of wire cross-section.

Another little device which ought to find an extensive sale if once users of electric light were shown its convenience, is a small clamp with socket attachment whereby an incandescent lamp could be clamped on each side of the mirror of an ordinary dresser. A pair of lamps could be easily clamped on each side of the mirror of each dresser and attached to existing fixtures or wall receptacles by means of extension cords and plugs. The arrangement would be almost ideal. At present if a man wants a light on each side of a mirror he must either put in two wall brackets or put some extra woodwork on the dresser on which to mount sockets.

Chicago, Ill. C. R. James.

A Problem in Motor Connections.

To the Editor, American Electrician:—

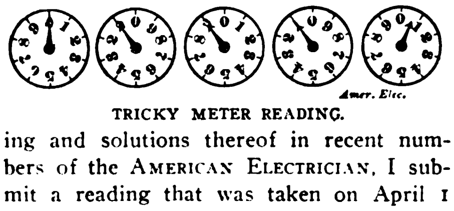
I have two series-wound motors, each wound for 110 volts and operated reversing. Two circuits are available for supplying the motors, one during one part of each day and the other during another part, so that the motors have to be shifted from one circuit to the other; one of the circuits supplies current at 110 volts and the other at 220 volts (not three-wire). The problem is to provide connections and switches between the two motors and the two circuits so that the motors may be operated on either circuit. When on the 220-volt circuit they must, of course, be connected in series with each other, and in parallel on the 110-volt circuit. It must be remembered that both motors are reversing machines. The wiring and switches must, of course, involve the most economical use of material, and be thoroughly practical; no specially designed switches which must be made to order can be used. I should like very much to have readers of the American Electrician suggest solutions of this problem.

Brookline, Mass. E. S. Lincoln.

Another Tricky Meter Reading.

To the Editor, American Electrician:—

Noticing Mr. Ryder's tricky meter reading and solutions thereof in recent numbers of the American Electrician, I submit a reading that was taken on April 1 which is not bad as a subject for consideration.



TRICKY METER READING.

Macon, Mo. Chas. Bennett.

[Solutions of Mr. Lincoln's problem and Mr. Bennett's meter reading intended for publication in the July number must reach this office not later than June 18. No solutions will be published in the August number. Readers desiring to submit solutions for criticism but not for publication are cordially invited to do so.—Editor.]

Voltage Disturbances from Paralleling Dynamos.

To the Editor, American Electrician:—

I noticed in your April number a letter from Mr. Ernest F. Hartwell in which he states that he has trouble from voltage fluctuations when connecting a generator to the bus-bar in parelle1 with operating machines. He did not say whether his generators were compound-wound or not, but I presume they are; from his description of his trouble, I also presume that each generator is controlled by a single triple-pole switch. If this is true, there is no wonder that the voltage fluctuates when machines are thrown into circuit. In order to avoid this and other disadvantages incident to the use of a single switch for all three terminals of a compound-wound generator, I have for many years followed the practice of using three single-pole switches for each generator, one in the positive lead, one in the negative, and the other in the equalizer lead. When a machine is to be thrown in, the positive and equalizer switches are thrown in first (the series winding is on the machine) and the machine is adjusted to the voltaage of the busbars by means of the shunt-field rheostat. Its series field being already parallel with the series windings on the active generators, there is no disturbance whatever when the third (negative) switch is closed to put the machine in parallel with its mates. The rheostat has to be readjusted slightly after the machine is connected in, but there is no disturbance of the bus-bar voltage. I suggest that Mr. Hartwell try this method of connecting up.

Fred P. De Wilde.
Butte, Mont.

[Mr. De Wilde's letter was received just as last month's issue was going to press, so that it could not be inserted in that number. The method he describes is quite widely used, except that the equalizer lead and the main lead on that side of the machine are connected to a double-pole switch instead of two single-pole switches; the results are exactly the same.—Editor.]

Wiring for Bells in Parallel.

To the Editor, American Electrician:—

I enclose three diagrams of bell connections for eight 5-in. vibrating bells located on eight floors and rung simultaneously from the ground floor. One friend contends that the proper way to connect the bells is in pairs, as shown in Fig. 1, ringing them one pair at a time. Another says that Fig. 2 is the best way to arrange the circuits in order to economize in material, insure reliable ringing and entail the least amount of trouble in signaling; the extra feed wire is to equalize the voltage at the bells and prevent the bells nearest to the battery from taking most of the current, and the use of a single push-button reduces the trouble of ringing to a single operation. The writer favors the simple method shown in Fig. 3. Which of the three is the best way to connect up? I should like to have expressions of opinion from you and readers of the American Electrician.

Chicago, Ill. R. B. Burton.

[Theoretically, Fig. 2 is preferable, but if the main line-wires are of sufficient cross-section and the bell magnets of sufficiently high resistance, Fig. 3 will give entirely satisfactory results. It might be advisable to connect the batteries in series-parallel to avoid drawing excessive current from the cells, but with high-resistance bell magnets this would not be necessary.—Editor.]

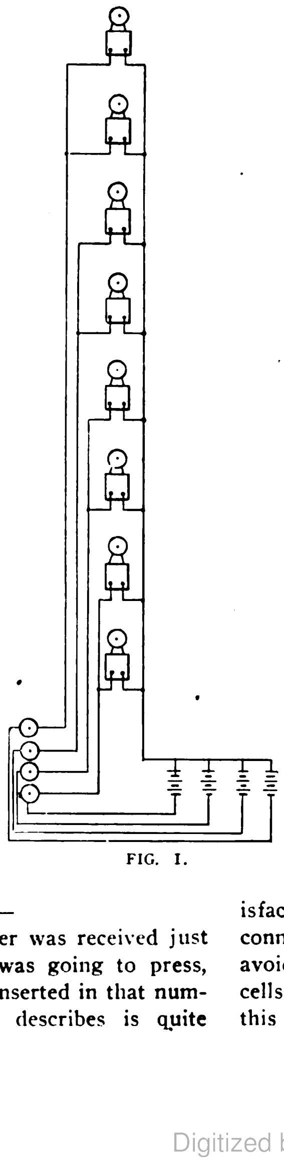


FIG. 1.

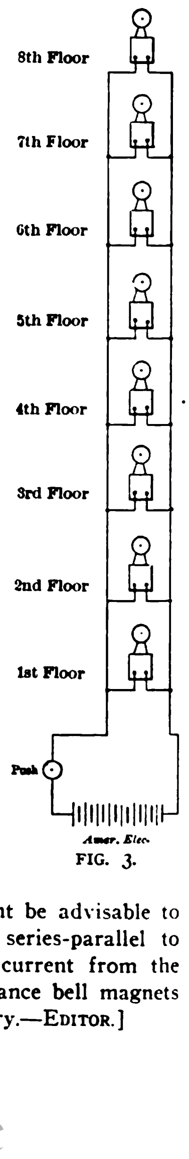

FIG. 3.

Queries and Answers

IMPORTANT.—No attention will be given to any inquiry which does not give the full name and address of the inquirer.

What brand of steel is best suited for the permanent magnets in telephone apparatus and magneto generators? A. D.

Tungsten steel. Chrome steel is also good.

Where can I get the castings for the voltmeter or ammeter described in the December, 1903, number? D. S.

Probably from J. C. Brocksmith, 488 Douglass Boulevard, Chicago.

Is not paraffine injurious to copper wire, or can the paraffine be made free from acid? (2) Please give data for a 6-in. spark coil. O. S.

No; it is free from acids. (2) We have no data for such a coil. "Electrical Designs" contains data for a 6-in. induction coil, if that is what is meant. The price is $2.

How can the power factor of an alternating-current multiple arc lamp be controlled in the construction of the magnets and choke coil? A. A. J.

The higher the resistance of the windings in comparison with their inductance, the better will be the power factor, but the lower will be the efficiency of the lamp; a compromise between the two is necessary.

What is the easiest practical way to change a 500-volt 15-h.p. 4-pole motor, with a two-path winding and two sets of brushes, so that it will work on a 220-volt circuit? J. E. McH.

Disconnect one armature coil and "dead-end" its terminals; bridge together two of the commutator bars at the point where one of the terminals of the discarded coil was connected, and connect up the remaining coils lap fashion. Add two more sets of brushes and connect the field winding in series-parallel.

How should the armature coils be wound and connected in a 12-pole, 12-coil alternator, the coils being of the pan-cake type? The machine is not compound-wound. G. A. B.

The coils may be all wound alike and the connections should be such that if direct current were sent through the armature it would circulate in opposite directions in any two neighboring coils. The coils may be all in series or connected in two parallel groups of six coils in series, according to the voltage desired.

Is it practical to operate ordinary telephone outfits on a grounded line 3000 feet long, with an intermediate station 750 feet from one end of the line, using dry batteries; if so, how many cells of battery should be used? (2) What size and kind of wire should be used? A. L. S.

Yes. Use the simple bridging sets, with a talking battery of two cells at each station, and magneto signalling apparatus. If battery signalling is essential, four or five cells and a push-button may be substituted for the magneto generator at each station. (2) No. 12 galvanized iron telegraph wire will answer, but No. 14 copper would be much better.

I have built a small motor with a gramme ring armature, but fail to get any results. The field magnet is strong, but the armature shows no magnetism when connected up to the circuit. What is the trouble? (2) Can dry batteries be used to supply three 6-c.p. incandescent lamps satisfactorily? W. H. R.

If your armature winding is connected to the commutator properly the trouble may be that the coils are not all wound in the same direction; they should all be exactly alike and the starting end of each coil should be connected to the final end of the next coil and to a commutator segment. (2) No; the battery renewals will be excessive.

How many turns of No. 30 magnet wire will be required for the voltmeter described in the December number to give full scale deflection at 10 volts? (2) How many turns and what size of wire will be necessary to wind the instrument as an ammeter giving full scale deflection at 5 amperes? (3) Will a water rheostat with round plates 8 ins. in diameter and 7 ins. apart have enough resistance to take up 70 volts with 5 amperes passing? H. M.

No. 30 wire cannot be used for such a low voltage; use No. 20 wire and put in as many turns as the bobbin will hold. (2) 130 turns of No. 12 wire. (3) Yes, but it will be much better not to limit the maximum distance between plates to 7 inches; 10 or 12 inches would be better for general use.

A three-wire circuit shows abnormal drop when the load comes on, so that the proper e.m.f cannot be maintained at the center of distribution, though the generators are strengthened to more than 20% above the rated voltage; what is the probable cause? (2) Why are automatic speed regulators not used on automobile engines? H. C. K.

The circuit wires are very much too small for the load or else one of your generators has reversed and the neutral wire is carrying a current equal to the sum of the currents in the outside wires. An ammeter in the neutral wire will show whether or not the latter is the case. (2) Because it is desired to operate the motors at widely different speeds; the change gears only give two or three speeds, intermediate gradations being obtained by varying the speed of the motor.

How can I figure the horse-power in the cylinder of an engine driving a dynamo which supplies 26 arc lamps requiring 50 volts each and 20 lamps requiring 75 volts each? All of the lamps take 6½ amperes. (2) How many amperes are equal to one horse-power? R. J. M.

You can't, unless you know the mechanical efficiency of the engine and the commercial efficiency of the dynamo. The dynamo will be supplying approximately $26 \times 50 \times 6\frac{1}{2} + 20 \times 75 \times 6\frac{1}{2} = 18{,}200$ watts, which are equal to about 24.3 horse-power; to this must be added the mechanical losses in the engine and all of the losses in the dynamo in order to ascertain how much horse-power is being developed in the engine cylinder. (2) Horse-power cannot be expressed in terms of amperes; multiplying amperes by volts will give the watts in a direct-current circuit, and dividing the watts by 746 gives the horse-power.

If the engine and generator of a direct-connected set reach full load simultaneously, how much overload can be given the generator without overloading the engine to a dangerous extent? (2) If the overload limit of the engine be exceeded, what will happen? (3) What range of cut-off does the ordinary automatic shaft governor give the valve? (4) If an engine having such a governor be designed for 350 r.p.m., how can the speed be reduced to 300 r.p.m.? E. B.

The question resolves simply into "What is the overload capacity of a dynamo, and what that of an engine?" The answer can only be given by the manufacturers of the dynamo and engine. (2) Either something will give way or the engine will slow down; usually the latter. (3) From zero to half stroke, on a single-eccentric engine and to about 0.7 of the stroke on a double-eccentric engine. In practice, the cut-off of a double-eccentric engine is rarely later than 0.65 of the stroke. (4) By reducing the tension of the governor spring or springs; if the weights are adjustable on their arms, they should be moved a trifle toward the free ends of the arms.

Two 125-volt 150-kw. direct-current generators operated on a three-wire system (one on each side of the neutral) give trouble from excessive voltage at full load; when the load reaches about 80% of full load, all of the rheostat is in circuit. The commutator and the bearing at the commutator end get extremely hot. What remedies would you suggest? The two machines are driven in tandem from a single driving pulley, and one of them runs hotter than the other regardless of the division of the load. F. M. L.

Adjust the shunt strips at the terminals of the series field windings until the machines compound properly without the manipulation of the rheostats; the strips must be shortened, so as to shunt more current away from the windings. The commutator heating may be partly due to the bearing, but is largely due either to too heavy tension at the brush springs or to insufficient contact area at the brush faces. The heating of the bearing may be due to roughness in the sleeve, improper operation of the oil rings, or insufficient clearance between the shaft diameter and the sleeve bore; the actual cause can be determined only by careful inspection.

How is the reading of a recording ampere-hour meter reduced to watt-hours? (2) What is a "constant" and how is it ascertained? (3) Is there any difference between frictional, dynamic and voltaic electricity? (4) Can the discharge of a condenser or a Leyden jar be measured while it is occurring? C. W. F.

Multiply the reading by the voltage of the circuit. (2) A constant is a factor or a number representing two or more factors which do not change; it is also a ratio between different systems of units. Thus, in a long formula containing several factors which always have the same values, these factors may be represented by a "constant" and the formula thereby simplified. Again, a dimensional formula expressed in metric measure may be made to express the same relations in English measure by inserting a "constant" which covers the ratios between the metric units and the English units. (3) Not qualitatively. The chief differences are in the magnitude of the voltage and current; static electricity is always at enormous potentials and the current of a static charge or discharge is extremely small compared with voltaic and dynamic electricity. The two latter differ chiefly in the magnitude of their voltages, but not so greatly as both differ from frictional or static electricity. (4) No; it occurs too quickly to be measured directly.

HIGH-VOLTAGE OIL SWITCHES.

The high-voltage switches made by the Stanley Electric Manufacturing Company of Pittsfield, Mass., are designed to break the circuit simultaneously at several points, so as to distribute the resulting disturbance over a considerable area. For potentials above 6600 the various contacts are arranged in the same horizontal plane so that the disturbances resulting from the arc are distributed rather than concentrated. This also has the advantage that the arc tends to flare upwards, increasing its length and thereby securing a longer break.

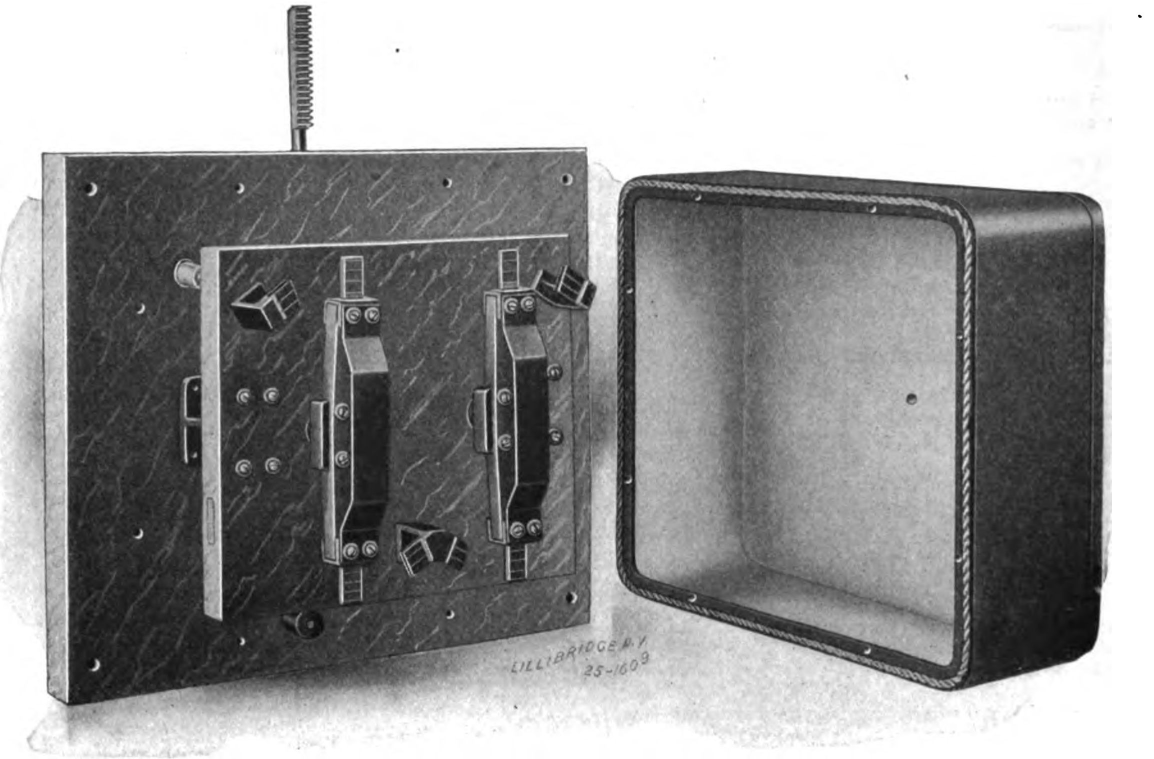

FIG. 1.—ONE POLE AND TANK OF 15,000 VOLT OIL SWITCH.

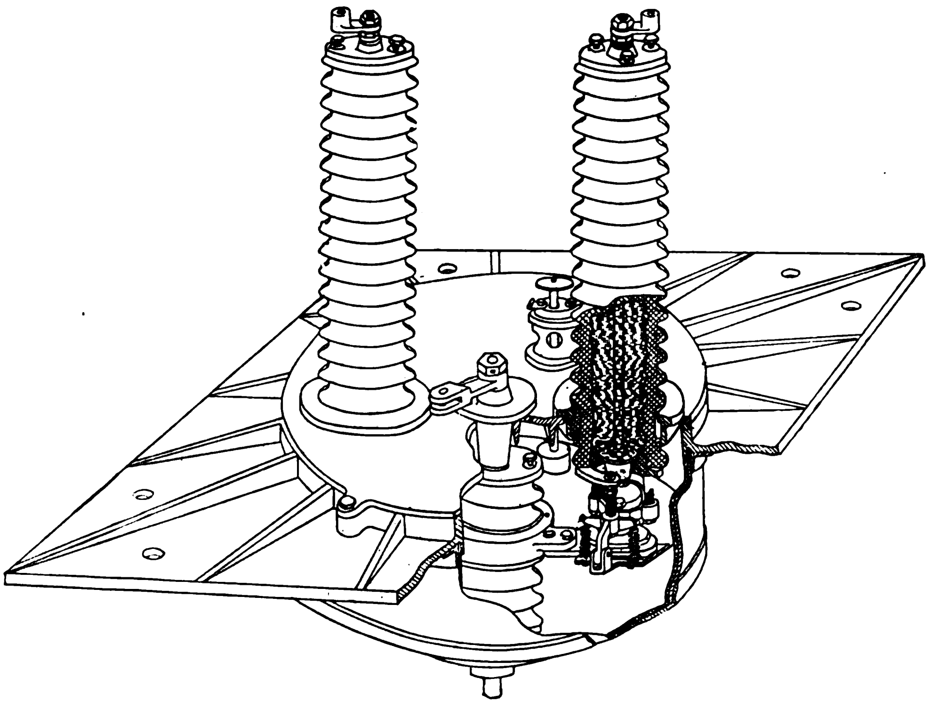

FIG. 2.—60,000-VOLT OIL SWITCH.

The contacts are located comparatively near the surface of the oil, so that the escaping gases are readily dissipated. These principles of construction are embodied in the new 300-ampere 60,000-volt switch recently brought out by the company. Fig. 2 gives a good idea of the construction of the switch. Each pole consists of, first, a cast iron top or mounting plate, on which are mounted the top terminal contact insulators, a bearing of liberal length for the driving shaft, and a combined gas vent and automatic oil level indicator; and, secondly, a tank filled with oil in which are immersed the contacts suitably insulated. The insulators are of porcelain made in the form of corrugated cylinders. The center insulator carrying the contact blades is entirely immersed in oil. The two terminal insulators are partly filled with and have their lower ends immersed in oil. These two insulators are held in position by means of hollow clamp rings which are fastened to the insulators with set-screws and cement. The contact blades are fastened to the central insulator in a similar fashion.

Fig. 3 shows the details of a contact. The contact arms are of hard-drawn flat copper strips. Each fixed contact is forced downward by three coiled springs which are carried on the studs on which the fixed contacts slide, and which are screwed on the bottom of the insulator. These fixed contacts, as well as the blades, have ground surfaces. On closing the switch, each contact blade slides under the corresponding fixed contact, and, owing to the arrangement of the springs, a self-aligned contact results.

The shape and position of the shunt or arc-rupturing contacts are said to be such as to prevent any possibility of the arc being taken by the main contacts. These auxiliary contacts are readily replaceable. In the illustration, the oil level indicator can be seen on the left of the insulator, the construction of which is exposed. Should

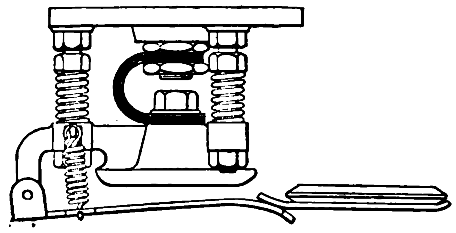

FIG. 3.—DETAILS OF CONTACT.

the oil leak out, or, for any other reason, recede below a safe level, the indicator closes the pilot circuit and warns the attendant by ringing a bell or lighting a lamp, as may be desired.

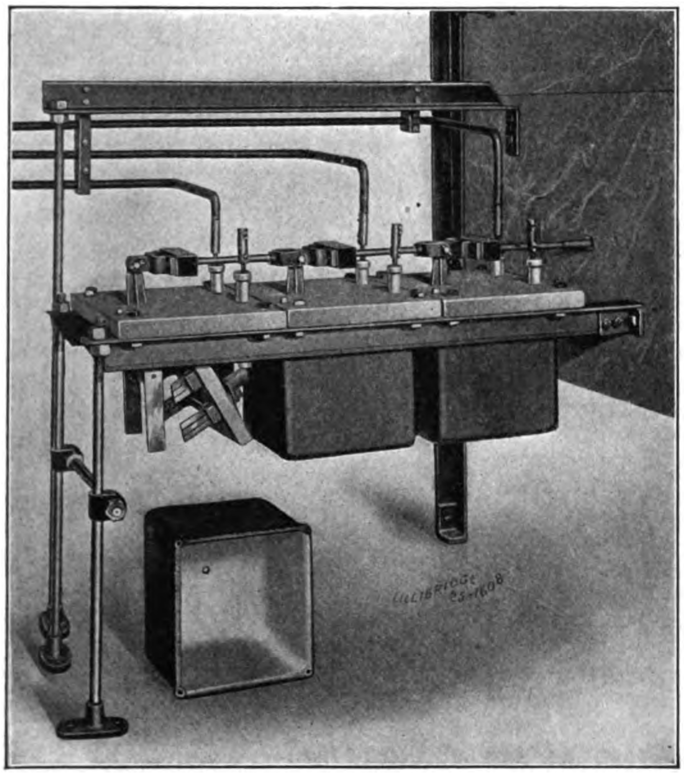

FIG. 4.—6600-VOLT THREE-POLE OIL SWITCH.

Each switch is tested and, in installing, the iron top and tanks are grounded, making it safe for the operator to handle the controlling device. The three-pole switch is made up of three of the units connected by rods, and the crank on each operating shaft is connected to either a motor, magnet or hand operated controlling device. The operation of either of these devices may be controlled by plain overload, time relay overload or reversed current relays. Each pole of the switch may be mounted in either a soapstone or brick compartment or upon iron framework.

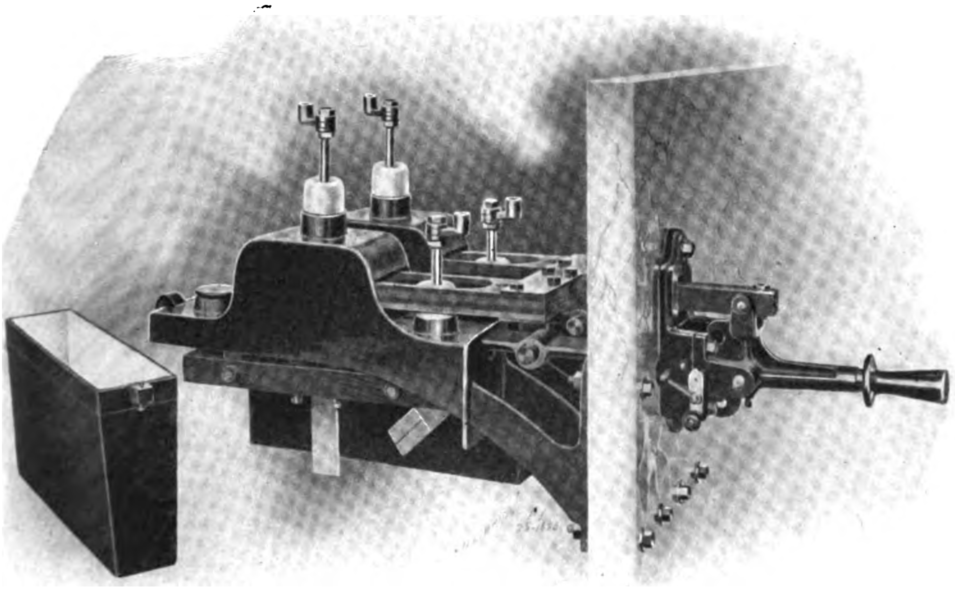

FIG. 5.—TWO-POLE TYPE "E" OIL SWITCH.

Fig. 1 shows one pole with tank of a 15,000-volt switch. As the contacts are arranged in series, it is evident that the circuit is broken simultaneously at four places, thus distributing the disturbance, as already noted. By connecting the two contact arms in parallel the switch has twice the carrying capacity, with half the breaking distance, and thus becomes suitable for currents of 200 amperes at 7500 volts. This type can also be used for 75 amperes at 20,000 volts, by changing the insulation carrying the leads.

This switch is also made double throw, another set of contacts being placed diametrically opposite those shown in the illustration. The tanks may be mounted either one above the other or in tandem, as may be preferred, or may be placed directly behind the board, or wherever convenient, and operated from the switchboard by means of connecting rods. This switch may, if desired, be equipped with circuit breaker attachment.

Fig. 4 shows a three-pole oil-switch for voltages up to 6600, and for currents up to 100 amperes. Each pole is in a separate tank and the tanks are mounted in a strong framework. The switch is made with circuit-breaker attachment, if so desired, and either single or double throw. One tank can be used as a double-pole switch with a capacity of 100 amperes at 2400 volts, by connecting one blade to each pole. By connecting the blades in parallel, instead of in series, the switch may be used for 200 amperes at 4000 volts. It is thus evident that this type of switch is readily adapted to meet a wide range of conditions.

Fig. 5 shows a type "E" oil switch, which is designed for installations of not over 3500 volts. It is made either single or double throw and for any number of poles desired. The normal three-phase capacity of the switch is 400 kilowatts and the emergency three-phase capacity is 1200 kilawatts.

The switch can be furnished with automatic, overload opening device. When so furnished, the handle for closing the switch is not connected rigidly to the parts making contact, but is latched thereto, the arrangement being such that it is impossible to close the switch when there is an overload or short circuit on the line. When these switches are furnished with this overload feature, series transformers are also supplied, but one being necessary for either a single-pole or two-pole switch and two for either a three-pole or four-pole switch. As in the company's switches for higher voltages, there is a separate tank for each pole.

◆

ELECTRICAL EXHIBITORS AT THE ST. LOUIS EXPOSITION.

The rapid advancement made in every line of invention since the Chicago Exposition provides a field of marvels for exhibition at St. Louis which will be at once remarkable and interesting. Following is a list of electrical exhibitors at the exposition, furnished by Prof. W. E. Goldsborough, chief of the department of electricity. The exhibitors from foreign countries, it will be noted, are not included:

Adams-Bagnall Electric Company, Cleveland; A. S. Aloe, St. Louis; American Carbon & Battery Company, St. Louis; American Circular Loom Company, Chelsea, Mass; American Electric Fuse Company, Chicago; American Electrical Heater Company, Detroit; American Electrical Novelty & Manufacturing Company, New York; American School of Correspondence, Chicago; American Telephone & Telegraph Company, Boston; the American Watchman's Time Detector Company, New York; American Watchman's Time Detector Company, Cleveland; Bion J. Arnold, Chicago; Association of Edison Illuminating Companies, Chicago; Martin Armstrong, St. Louis; Atlanta Utility Works, East Point, Ga.; the Automatic Electric Company, Chicago; Automatic Fire Alarm Company, New York City; Argentine Republic.

Baird Manufacturing Company, Chicago; Carl Bajohr, St. Louis; Bario Vacuum Company, New York; M. V. Barlow, Chicago; W. M. Bashlin, Warren, Pa.; Mrs. Alexander Baumgart, New York City; Benjamin Electric Manufacturing Company, Chicago; The Bristol Company, Waterbury, Conn.; The Browning Company, Milwaukee; The Bryant Electric Company, Bridgeport, Conn.; Bullock Electric Manufacturing Company, Cincinnati; Burdette-Rowntree Manufacturing Company, Chicago; Burnham-Williams & Co., Philadelphia.

H. B. Camp Company, Chicago; Carbondale Machine Company, Carbondale; Cassidy & Son Manufacturing Company, New York; Carman Projector & Specialty Company, Chicago; Central Telephone & Electric Company, St. Louis; Chicago Fuse Wire & Manufacturing Company, Chicago; Colonial Sign Company, Akron, Ohio; Chicago X-Ray Company, Chicago; James Clark, Jr., & Co., Louisville; A. Frederick Collins, New York; Commercial Electric Company, Indianapolis; Controller Company of America, St. Louis; Cooper Hewitt Electric Company, New York; Crocker-Wheeler Company, Ampere, N. J.

The Dayton Autoelectric Company, New York City; De Forest Wireless Telegraph Company, New York; Patrick B. Delany, South Orange, N. J.; The Dayton Electrical Manufacturing Company, Dayton, Ohio; Dialt Motor Company, Philadelphia; Dicke Tool Company, Downers' Grove, Ill.; Dodd & Struthers, Des Moines, Iowa; S. R. Dresser, Bradford, Pa.

Economical Electric Lamp Company, New York; Thomas A. Edison, Orange, N. J.; Electra Water Purifier Company, St. Louis; Electric Circulator Company, Chicago; Electric Contract Company, New York; Electric Controller & Supply Company, Cleveland, Ohio; Electric Railway Equipment Company, Cincinnati; Electric Storage Battery Company, Philadelphia; Eureka Tempered Copper Works, North East, Pa.

Faller Automatic Telephone Exchange Company, New York; Federal Electric Company, Chicago; C. J. Field, New York; Fort Wayne Electric Works, Fort Wayne, Ind.; France.

Germany; The Gardner Electric Drill & Machinery Company, Cleveland; General Electric Company, Schenectady, N. Y.; Gervais Manufacturing Company, Edgewater, N. J.; G. M. Gest, Cincinnati; W. E. Goldsborough, Lafayette, Ind.; Gould Coupler Company, New York; Gould Storage Battery Company, Depew, N. Y.; Gray National Telautograph Company, New York; Gray Telephone Pay Station Company, Hartford, Conn.; A. Grothwell, San Francisco, Cal.

C. F. Hall, Chicago; Robert E. Haward, Kansas City, Mo.; The Heinze Electric Company, Lowell, Mass.; Hellesens, Enke & V. Ludvigsen, Copenhagen, Denmark; Hinton & Tarkington, Hot Springs, Ark.; Holmes, Booth & Haydens Company, New York; Holophane Glass Company, New York; C. W. Hunt, West New Brighton, New York; Miller Reese Hutchison, New York City; Hutchison Acoustic Company, New York.

Italy; Indiana Novelty Company, Muncie, Ind.; International Acheson Graphite Company, Niagara Falls, N. Y.; J. Van Inwagen, Momence, Ill.

The Jackson Electric Drill & Supply Company, Denver, Colo.: The Jandus Electric Company, Cleveland.

Charles Kaestner & Co., Chicago; Kellogg Switchboard & Supply Company, Chicago; Kester Electrical Manufacturing Company, Chicago; Keystone Electrical Instrument Company, Philadelphia; The Kny-Scheerer Company, New York; H. E. King, Chicago; D. A. Kusel Telephone & Electric Manufacturing Company, St. Louis.

The Leclanche Battery Company, New York; Lincoln Electric Company, Cleveland; Lionel Manufacturing Company, New York; Locke Insulator Manufacturing Company, Victor, N. Y.

Mexico; McGraw Publishing Company, New York; McRoy Clay Works, Chicago; Marshall-Sanders Company, Boston; W. E. Matthews & Brother, St. Louis; The Miller Anchor Company, Norwalk, Ohio; Mystic Electric Gas Lighter Company, New York; Moloney Electric Company, St. Louis.

National Carbon Company, Cleveland; National Battery Company, New York; National Cash Register Company, Dayton, Ohio; National Electric Company, Milwaukee, Wis.; Nernst Lamp Company, Pittsburg; National Clock Works, St. Louis; Northern Electrical Manufacturing Company, Madison, Wis.; Norton Emery Wheel Company, Worcester, Mass.; Nungesser Electric Battery Company, Cleveland.

The Organ Power Company, Hartford, Conn.

Pawling & Harnischfeger, Milwaukee, Wis.; The Peerless Electric Company, Warren, Ohio; Perkins Electric Switch Manufacturing Company, Bridgeport, Conn.; The Phelps Company, Detroit, Mich.; Walter P. Phillips, Bridgeport, Conn.: Pittsburg Blue Print Company, Pittsburg; Pneumatic Signal Company, Rochester, N. Y.; Postal Telegraph Cable Company, St. Louis; Printing Telegraph News Company, St. Louis; Prometheus Electric Company, New York City; Produce Research Laboratory, Lafayette, Ind.; Portugal.

Queen & Co., Philadelphia; F. Herrero y Ruix, Albacete, Spain.

Reynolds Electric Flasher Manufacturing Company, Chicago; The Robbins & Myers Company, Springfield, Ohio; Chicago Röntgen X-Ray Laboratory, Chicago; Roth Brothers & Co., Inc., Chicago.

St. Louis Brass Manufacturing Company, St. Louis; the Safety Insulated Wire & Cable Company, New York; Sawyer-Man Electric Company, New York; W. Scheidel & Co., Chicago; M. Shearer, Akron, Ohio; Shedd Electric & Manufacturing Company, New York; Standard Underground Cable Company, Pittsburg; Standard Water Purifying Company, Cleveland; Sterling Electric Company, New York; Sterling Electric Motor Company, Dayton, Ohio; S. W. Stratton, Washington, D. C.; William F. Stilz & Co., Philadelphia; Sumter Telephone Manufacturing Company, Sumter, S. C.

Telephone Hygienic Company, Los Angeles, Cal.; C. H. Thordarson, Chicago; C. J. Toerring Company, Philadelphia; Triumph Electric Company, Cincinnati, Ohio.

Underwriters' Laboratories, Chicago; U. S. Incandescent Lamp Company, St. Louis; United States Electric Signal Company, West Newton, Mass.

E. C. Van Nort Electric Company, St. Louis.

Wagner Electric Manufacturing Company, St. Louis; R. V. Wagner & Co., Chicago; Waite & Bartlett, New York; Warren Ball-Bearing Fixture Company, New York; Warren Electric & Specialty Company, Warren, Ohio; Warren Electric Manufacturing Company, Sandusky, Ohio; B. F. Wasson, Clinton, Ill.; Western Electric Company, Chicago; Wesco Supply Company, St. Louis; *Western Electrician*, Chicago; Western Union Telegraph Company, St. Louis; Weston Electrical Instrument Company, Newark, N. J.; Westinghouse Electric & Manufacturing Company, Pittsburg; Wheel Truing Brake Shoe Company, Detroit, Mich.; Windsor & Kenfield Publishing Company, Chicago; Wireless Railway Company, Philadelphia; Westinghouse Traction Brake Company, New York; The Wyckoff Pipe & Creosoting Company, Stamford, Conn.

Charles E. Yetman, New York.

A NEW MOTOR-DRIVEN PUMP.

Fig. 1 herewith illustrates an extremely compact and effective combination of duplex pump and electric motor which is being marketed by Charles S. Pease, New York. The pump is of special design, for which Mr. M. W. Hall is responsible. The plungers are driven from two large crankpins on opposite ends of the pump shaft; mounted on the center of this shaft is a worm wheel which meshes with a worm on the end of the motor shaft. All of this gearing is enclosed in the lower casing of the pump structure and submerged in oil, so that no lubrication from the outside is required. The construction of the pump proper is very unusual, and one of the strong features of the combination; it is not practicable to describe this construction adequately without illustrations of the details, and these are unfortunately not available now on account of the patent status. These little pumping outfits are admirably adapted for supplying water tanks on office buildings, hotels, residences and apartment houses; they are said to be entirely noiseless, and since no external application of lubrication is necessary and the switch controlling the motor is of the usual automatic-float type, the motor and pump will run for months without any attention. Any of the standard motors are supplied, according to the preference of the purchaser.

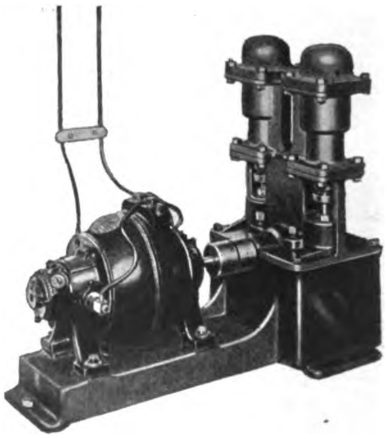

FIG. 1.—MOTOR-DRIVEN PUMP.

New Apparatus and Appliances

ELECTRICIAN'S TOOL CHESTS.

Fig. 1 herewith shows a steel tool chest for electricians manufactured by William Vanderman, of Willimantic, Conn. The chests are made of cold-rolled 3/16-in. sheet steel with malleable iron corner pieces and hard wood braces. They are fitted with heavy wrought iron hinges and hasp, and the cover is so arranged as to be held open by a support from the back of the chest. Each chest is furnished with a brass lock and two keys, and bolts to screw down the cover at the front corners. The chests are painted, well proportioned and ornamental in design. They are made in six styles and four sizes to each style.

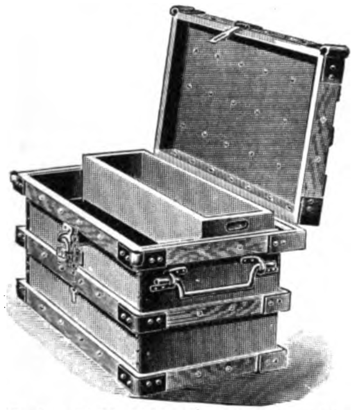

FIG. 1.—ELECTRICIAN'S TOOL CHEST.

A NEW TESTING SET.

Machado & Roller, the selling agents of the Whitney Electric Instrument Company, are marketing a new form of testing set, of which an illustration is presented herewith. It is of the decade pattern in which the drawbacks incident to the great number of plugs necessitated by the old Post Office form of construction are eliminated, there being but four plugs in the rheostat itself. It will be noticed that the use of reversing blocks in the bridge arms has been done away with by adding an extra coil to each arm. This expedient eliminates two plugs and makes the operation of the set more easy to understand. The keys are of a novel form which can be operated independently or like the conventional combination key, whichever is desired. Five large dry cells are built into the containing case and a flexible cord with plug is arranged so that any number of them can be used at will. An ingenious modification of the ordinary construction of decade and post office sets is used to shift the internal connections from those employed in making ordinary resistance measurements and the Murray test to the connections for the Varley test, so that the two "X" posts common to every bridge are the ones to which the outside line is always attached no matter what test is being made thereon. A pair of binding posts to which an external galvanometer of the reflecting form may be attached for very sensitive work is also provided and by shifting one plug, either this external galvanometer or the one that is built into the set is brought into play. Another pair of posts permits the use of an external source of electro-motive force where this is desired. Instead of following the conventional procedure of marking the ratio arm blocks "A" and "B," they are stamped "Divide by" and "Multiply by" respectively, the connections being such that, when a plug is inserted in the gap between the "divide by" block and any one of the four circular blocks opposite thereto, the readings as indicated by the position of the plugs in the rheostat are to be divided by the number stamped on the circular block to get the correct reading. Similarly, the resistance plugged in in the rheostat is to be multiplied by the number indicated by the position of the plug in the "multiply by" ratio arm block. The plug blocks for changing over the loop and galvanometer connections are marked with similar clearness so that practically anyone can use the bridge without chance of confusion. The actual diagram of connections is as shown by the line cut herewith. An accuracy of adjustment of a tenth of one per cent throughout is claimed, and it is also stated that the galvanometer is sufficiently sensitive to give a marked deflection with a tenth of a per cent resistance variation when working with full battery power on a resistance of moderate value. The galvanometer is not affected by external fields and can be used with the set in any position.

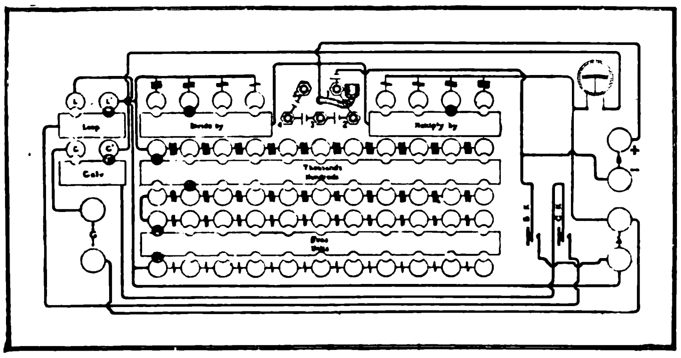

FIG. 2.—DIAGRAM OF CONNECTIONS.

ELECTRICALLY OPERATED WHISTLES.

Fig. 4 herewith shows a solenoid attachment brought out by the Electrical Appliance Company, of Cincinnati, Ohio, by means of which a steam or other kind of whistle may be operated from a distance by simply pushing a button, or by a clock which automatically makes the contacts at the desired times. The device is said to operate any whistle up to 3 ins. in diameter which is under a pressure of 150 pounds, or when provided with larger valve will operate a 6-in. whistle under the same pressure. Where the available current is alternating, a Churcher rectifier is supplied with the outfit.

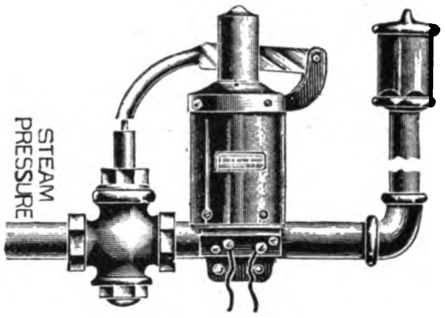

FIG. 4.—ELECTRICALLY OPERATED WHISTLE.

P-K ATTACHMENT PLUGS.

Figs. 5 and 6 show two of a line of P-K attachment plugs for 1904 which cover both the brass cap and porcelain types. The new "Pushin" type shown by Fig. 5 operates on an entirely new principle, as it is inserted and attached by simply pushing it into the socket, without any twisting of the cord. The two side springs, formed in ex-

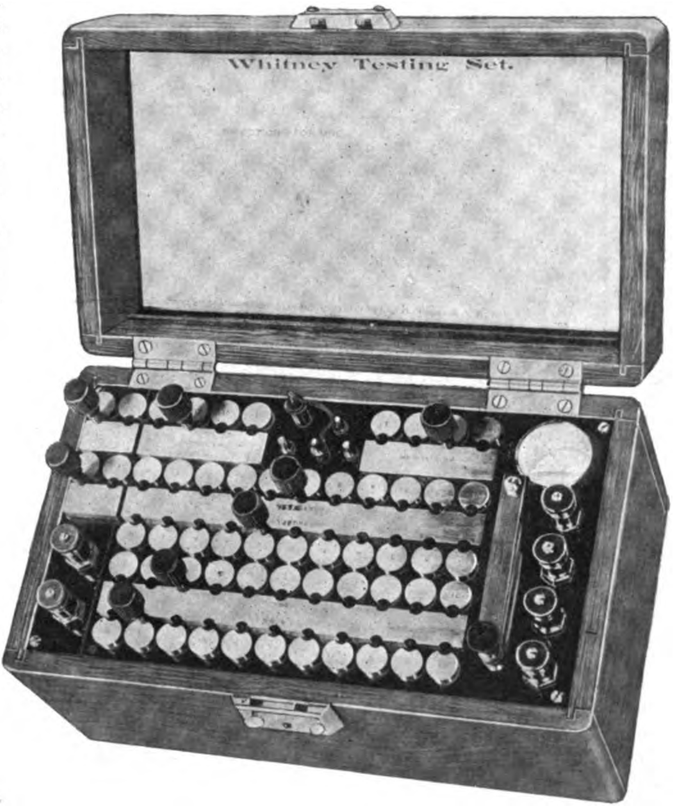

FIG. 3.—WHITNEY TESTING SET.

act shape to fit the Edison screw shell, securely hold the plug in place, while a third spring at the end completes the circuit. These springs are all of special phosphor-bronze. The No. 430, shown by Fig. 6, is the standard "P-K" attachment plug and is made for Edison, T-H and Westinghouse bases. The brass caps are fiber lined with fiber-bushing already in place in the cord opening. These caps are securely held by two side screws which enter recesses in the porcelain base. All styles of "P-K" attachment plugs have cord-openings at least 3/32" in diameter, so they are easily wired with reinforced show window cord. The plugs are made by the H. T. Paiste Company, of Philadelphia.

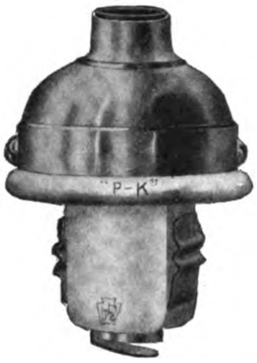

FIG. 5.—"PUSHIN" PLUG.

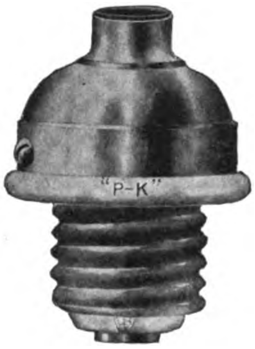

FIG. 6.—"P-K" ATTACHMENT PLUG.

ANDRAE O. K. DISTRIBUTION BOX.

Fig. 7 herewith shows a patented junction box brought out by the Julius Andrae & Sons Company, of Milwaukee, Wis., which is claimed to be at once a switchboard, testing board and junction box. The box is of cast metal and the front side has a removable cover with brass bolts and screw connections, and is provided with a rubber gasket to keep out the moisture. The bottom of the box has two or more tapped openings for screw threaded brass nipples, engaged by the cables, and these brass nipples and cables are united by soldering joints. Looking into the box is seen an insulating base of hard rubber, and by means of screws this insulating base is fastened to a ledge projecting from the sides and ends of the box. The insulating base is provided with brass contacts mounted on hard rubber ribs, to which wires leading from the cables are attached, being first put through small individual openings, bringing same to the front; each connection, therefore, is in plain view and work can be performed with rapidity. An insulating compound is poured into the rear of the box—back of the diaphragm, through an opening provided on top of the box, and when completely filled the opening is closed by a screw plug. Each box is provided with two goose necks, which can be attached whenever necessary under the front of the box, through which wires are brought out to the pole or elsewhere after which these goose necks are filled with an insulating compound. The device affords an easy and quick access to each conductor of a cable for connecting, disconnecting, cross-connecting and testing. It also allows the quick locating and cutting out of any defective portion of a system.

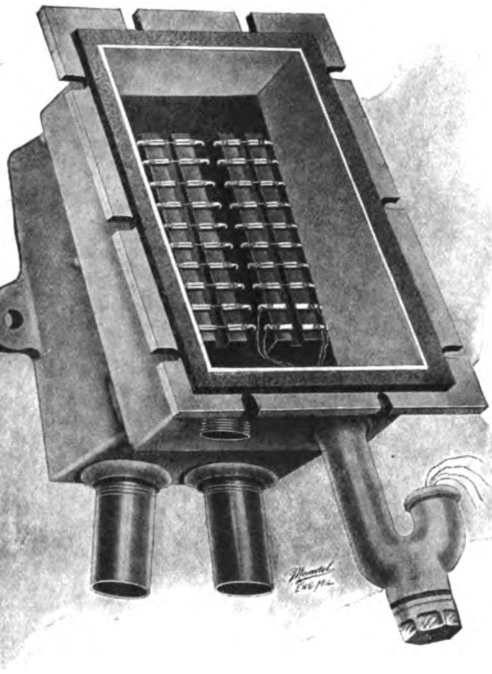

FIG. 7.—UNDERGROUND DISTRIBUTION BOX.

MOTOR-DRIVEN BUFFING LATHES AND DRY GRINDERS.

In order to supply the demand for effective electric motor-driven buffing lathes and dry grinders a line of these have been placed on the market by the Bridgeport Safety Emery Wheel Company and the Crocker-Wheeler Company. It is a complete line of motor-driven tools of this class of extremely neat and effective construction. Instead of extending an ordinary motor spindle and making a base to fit the motor, the emery wheel builder supplies shafts upon which the Crocker-Wheeler Company mount their armatures. The shaft is larger and stronger than necessary for an ordinary motor shaft and supported by unusually long bearings to secure rigidity against the vibration to which these tools are subject. The design of the motor is slightly modified to make the two a harmonious unit in every particular. Machines of this class must of course be fully inclosed, and the problem of cooling by air is a serious one. This has been solved by having the lower half of the motor open directly into the base casting. The air contained in the inside of the base is thus added to the quantity that circulates around the inside of the motor, and enables it to run much cooler than an ordinary fully inclosed motor of the same size and capacity. By this means of inclosure from five to eight times as much cooling air is said to be available as in ordinary fully inclosed motors of equal power, the base also giving an in-

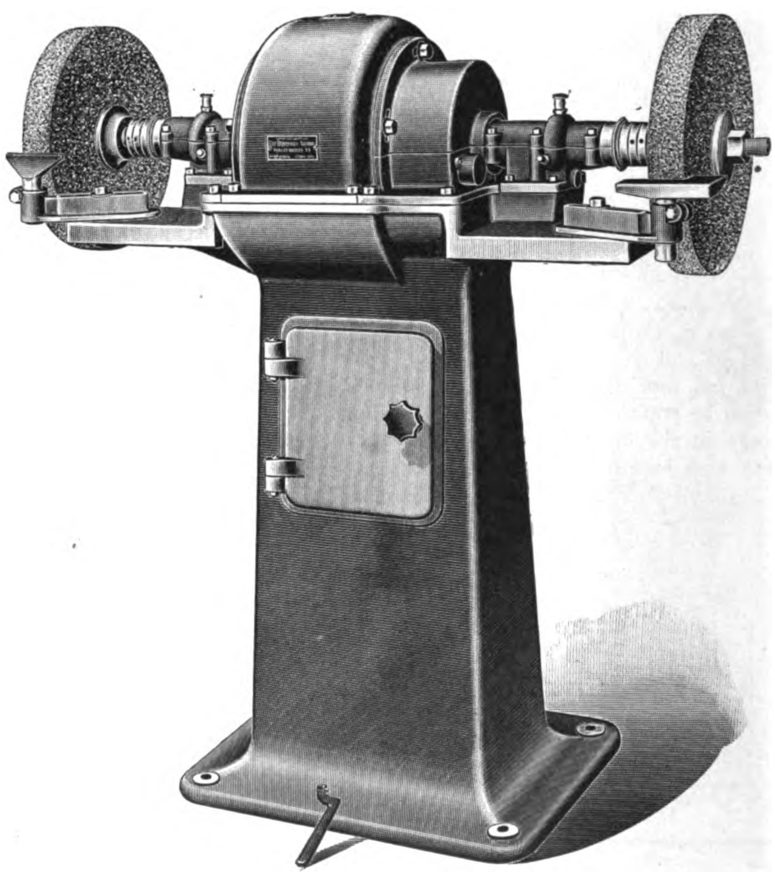

FIG. 8.—MOTOR-DRIVEN BUFFING LATHE AND DRY GRINDER.

creased surface from which to radiate the heat. The armature and brush mechanism is covered with an end shield, split horizontally. The lower half contains the brush holders and wire connections; the upper half is attached to the motor frame by cap screws. This upper half of the frame can thus be readily taken off, giving quick and easy access to the armature and brushes. The machines are equipped with ring oiling bearings. On the outer end of each box is a dust proof collar, held in place by a key with two ring nuts, to compensate for all end wear and thrust of the spindle. The machines are strong, rigid, compact and self-contained. All wires and connections being inside, a short circuit through outside terminals is impossible. The starting box and switch are inside the base and are easily reached by the operator through a door. The machines can be used with either underneath or overhead wiring as desired, and are complete with starting- box with no-voltage release, knife switch, and fuses ready to connect line wires.

TRUMBULL PORCELAIN BASE SWITCH.

Fig. 9 herewith shows a new porcelain base switch brought out by the Trumbull Electric Manufacturing Company, of Plainville, Conn. This is a modification of the type "B" switch made by the same company and has been designed with a view to making a cheaper switch, while at the same time not reducing the efficiency. The switch has been adapted to a porcelain base and, it is said. conforms to the underwriters' requirements. All of the metal parts are made of pure copper, with hard fibre cross bars. The switch has the same spring finger contact as the regular type "B" switch.

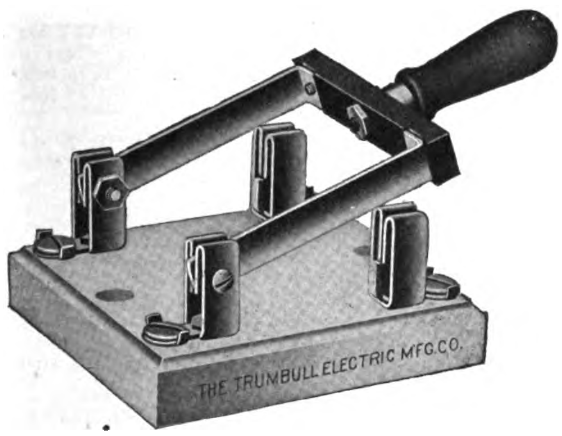

FIG. 9.—PORCELAIN BASE SWITCH.

STURTEVANT IMPROVED HAND BLOWERS.

The accompanying illustration shows a new design of hand blower brought out by the B. F. Sturtevant Company of Boston, Mass. This is known as type "B" and is an improved form of type "A" built by the same company. They are not only adapted to forge blowing but can readily be applied as portable ventilating apparatus. The running gear is simple, effective and strong. The blower is adjustable on the shaft, and its outlet may thus be set to discharge in any direction and is readily connected to the forge tuyere by means of galvanized iron piping. The blower is of cast iron. It has a steel shaft running in babbitted boxes and a fan wheel of galvanized steel solidly riveted to a composition hub with extending arms. The frame is arranged so that the slackness of the belt driving the blower may be taken up by lowering the blower shaft which is supported by collars sliding on the frame. The feet are provided with holes so that the blower may be screwed to the floor. These hand-blowers are made in two sizes. The total length on the floor of Style B-1 is 18 inches, while the total height of the frame, not including the handle, is 48 inches. The driving wheel is 24 inches in diameter, the blower outlet is 3½ inches in diameter and the complete outfit weighs but 135 lbs. Style B-2 is of slightly larger dimensions and has proportionately greater capacity for delivering air. The driving wheel is 24 inches in diameter, the blower outlet is 4¾ inches in diameter and the complete outfit weighs 155 lbs.

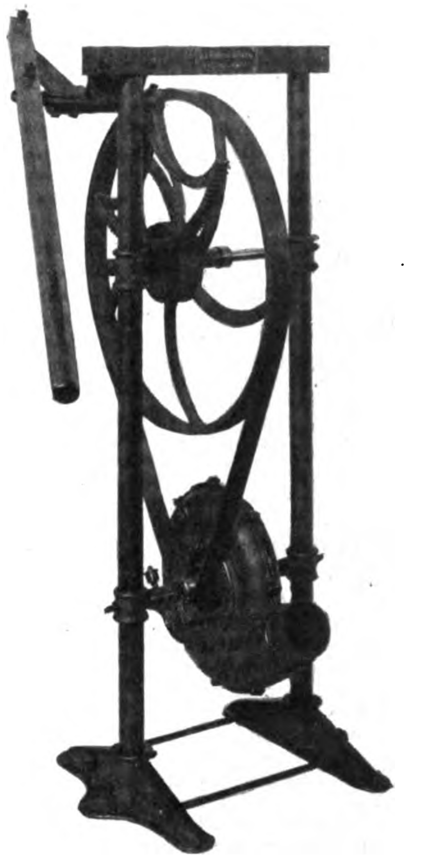

FIG. 10.—STURTEVANT HAND BLOWER.

NEW FORM OF FUSE.

A new fuse that has just been introduced by the Horton-Massnick Company, of Detroit, Mich., is illustrated by Fig. 11 herewith. The fuse is especially for set-screw contacts with centers which engineering practice has established. Both terminals are flexible and will take any centers from 1⅜ inche to 3 inches. The fusing material is formed in the shape of the letter U and is entirely surrounded by finely divided refractory material, with the exception of a very short portion, which is exposed to view through a hole in the bottom of a brass cap, which seals the open end of the fuse case or tube. The hole in the brass cap is covered by a transparent disc and the fuse is so constructed that the fusing material will blow exactly under this window. The user can determine at a glance whether or not the fuse is blown, because he can see the fusing material itself or the blackened window resulting from the blown fuse. The fuse is designed for 250-volt work and can be furnished in capacities from 1 to 30 amperes.

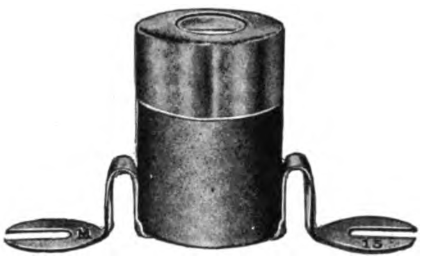

FIG. 11.—HORTON-MASSNICK FUSE.

NEW BOOK.

DYNAMO ELECTRIC MACHINERY. (Seventh Edition.) By Prof. Silvanus P. Thompson. New York: Spon & Chamberlain. Buckram; 996 pages, 5½ ins. x 8½ ins.; 573 illustrations; numerous tables; 30 construction plates. Price, $7.50.

The present edition of Prof. Thompson's well-known text book contains a great deal of new material which includes most of the matter in his recently-issued "Design of Dynamos," and the old material has been very fully revised. The author has at last adopted the method of dealing with electromagnetic exciting force on the basis of ampere-turns per unit length of magnetic path, which was used by the reviewer twelve years ago, and has been in general use in this country for at least nine or ten years. The exposition of fundamental principles remains practically unchanged, of course, in the new edition, but the details of construction, methods of design and other features which change with progress in the art have been brought up to date. This is especially noticeable in the sections devoted to armature construction, commutators and brushes, losses and heating, analysis of dynamo design and examples of modern machines. Many of the author's empirical rules do not agree with American practice, and it is difficult to see how some of them can agree with actual practice anywhere; for example, his assumptions that the effective air-gap area is the mean of the pole-face area and the area of the tooth tops under the pole, and that the field ampere-turns required to drive the flux through the armature teeth can be based on the magnetic density in the top or widest part of a tooth (page 613). Unless the teeth are worked at densities far below any practice thus far published, the effective air-gap area must be considerably greater and the magnetomotive force demanded by the teeth will be very much higher than the author's rules would provide. However, in view of the splendid material contained in the book, these discrepancies are insignificant. An excellent chart showing the magnetic properties of sheet steel at very high densities and other materials at ordinary densities has been added, and will doubtless be of great convenience to European designers using the brands of iron and steel from which the curves were plotted. There are also new sections on special types of dynamos, motor-generators and boosters, and rheostats, controllers and motor starters. The material on alternating-current apparatus which was in the previous edition has been omitted altogether to make room for the new matter on direct-current machinery, and will, presumably, be revised and published in a separate volume, the present book being designated Volume I.

PERSONAL.

MR. S. P. SHEERIN, president of the Indianapolis Telephone Company, recently sailed for Europe with Mrs. Sheerin for a three months' rest.

MR. C. S. PLATT has been appointed Eastern representative of the Sterling Electric Company, of La Fayette, Ind., with headquarters at 346 Broadway, New York.

MR. IRVING A. TAYLOR, who has had a wide experience in central station and high-tension transmission work, has joined the staff of the Engineering Company of America.

MR. JOHN B. ALLAN has resigned his position of general sales manager for the Allis-Chalmers Company and expects to take a two-months' vacation before again engaging in active work.

MR. W. A. ROSENBAUM, the well-known patent attorney, has formed a copartnership with Mr. W. M. Stockbridge under the style of Rosenbaum & Stockbridge. The firm's headquarters are at Mr. Rosenbaum's old address, 140 Nassau Street, New York.

MR. J. T. P. KENYON has resigned from the New York Edison Company's engineering department to accept the position of chief draughtsman of the New York Central & Hudson River Railroad Company's electrical department.

MR. R. A. FLIESS, who has been associated with Mr. Edison for the past few years in the development of the new Edison storage cell, delivered a very interesting lecture before the New York Electrical Society on April 27.

MR. H. V. CROLL, who has for several years had charge of the Allis-Chalmers Company's Salt Lake City office, has been transferred to the management of the San Francisco office of that company, which is at 623 Haywood Building.

MR. FRED W. WALTER has established an office at Norfolk, Va., for the representation in that vicinity of several well-known manufacturers. Among those whom Mr. Walter will represent are the C. & C. Electric Company and the Stanley Electric Manufacturing Company.

LIEUT.-COMMANDER J. B. BLISH, who has for the past six months been inspecting the apparatus built for the U. S. Navy at the General Electric Works in Schenectady, has been compelled to abandon his work there temporarily on account of illness, and is now at the New York Naval Hospital under treatment.

MR. LYMAN C. REED has severed his connection with the Interstate Electric Company, New Orleans, and formed a partnership with Mr. William T. Spranley for the purpose of engaging in contract electrical engineering. The style of the firm is Spranley & Reed, and their headquarters are in the Hibernia Bank Building, New Orleans.

MR. GEORGE A. FULLER, retiring assistant electrical engineer of the Schenectady Railway Company, was given a banquet recently at the Hotel Ten Eyck, Albany, by the railway company's staff. The general manager, Mr. E. F. Peck, officiated as toast master, and Superintendent Frederick Smith presented Mr. Fuller with a set of solid silver back brushes.

MR. PUTNAM A. BATES, who recently resigned the sales management of the Crocker-Wheeler Company, and Mr. John Neilson have formed a copartnership for the practice of consulting electrical engineering. The style of the firm is Bates & Neilson, and its headquarters are at 42 Broadway, New York. Both members of the firm are splendidly qualified by long experience for the class of work they have undertaken.

MR. J. H. HALLBERG, the well-known authority on electric arc lighting, who was for several years in charge of that department of the General Incandescent Arc Lighting Company's business, and recently added to his fame by reorganizing the arc lighting system of the Cincinnati Gas & Electric Company, has decided to engage in consulting engineering on his own account. Mr. Hallberg will devote his attention to electrical distribution and illumination and has established headquarters at 45 Broadway, New York.

TRADE PUBLICATIONS.

WIRE ROPE AND FITTINGS. American Steel & Wire Company, Chicago and New York.—This is the 1904 edition of the company's catalogue of wire ropes, sheaves, clamps, end sockets, thimbles, and other appliances used in connection with such rope.

WOOD ALTERNATOR INSTRUCTION BOOK. Ft. Wayne Electric Works, Ft. Wayne, Ind.—This is instruction book No. 3019 and contains a complete description of the well-known Wood alternators, with full instructions for operating and general handling.

DISC VENTILATING FANS. American Blower Company, Detroit, Mich.—Catalogue No. 161, devoted to the well-known A.B.C. disc fans which were fully described in the March number of this paper. These fans are built, of course, for any of the standard methods of driving.

SINGLE-PHASE INDUCTION WATTMETERS. Ft. Wayne Electric Works, Ft. Wayne, Ind.—This is Bulletin No. 1053, superseding Bulletin No. 1017 and describing the Ft. Wayne "Type K" integrating watt-hour-meter for single-phase alternating-current circuits.

MAGNETO CIRCUIT CLOSER. The Holtzer-Cabot Electric Company, Boston.—Bulletin No. 206, describing a sensitive relay which is operated by magneto current and arranged to close another circuit when so operated. The main circuit remains closed until the apparatus is reset.

DIRECT-CURRENT GENERATORS AND MOTORS. National Electric Company, Milwaukee, Wis.—This is catalogue No. 61 and contains profusely illustrated descriptions of the extensive line of direct-current machinery built by this company. The catalogue is executed in the handsome style characteristic of the company's publications.

MAGNETO RECORDING CLOCKS. The Holtzer-Cabot Electric Company, Boston, Mass.—Bulletin No. 152, containing an illustrated description of the Holtzer magneto clocks for recording watchmen's signals. These clocks are made to record signals from any number of stations up to 25, and, when desired, are provided with two or three recording dials.

SWITCHBOARDS. The F. Bissell Company, Toledo, Ohio.—A very complete pocket size pamphlet containing a list of complete switchboards for different classes of service. The dimensions of each type of switchboard are shown by an outline drawing, and a detailed list of the apparatus with which the board is equipped is printed alongside the drawing.

ELECTRICAL AND STEAM MACHINERY. Rossiter, MacGovern & Co., Inc., New York.—A very compact list of second-hand apparatus for sale on May 1. All of the apparatus sold by this company is thoroughly overhauled at one of its factories and put in first-class operating condition before it is offered for sale. The present list includes almost every class of electrical and allied machinery.

BUSINESS NEWS.

THE WHEELER CONDENSER & ENGINE COMPANY has moved its New York offices to 42 Broadway.

AUBURN BALL BEARING COMPANY has removed its main office and works from Auburn to 18 Commercial Street, Rochester, N. Y.

STANLEY & PATTERSON, Inc., New York, have removed their general offices and salesrooms from 93 Liberty Street to 40 Cortlandt Street.

THE GENERAL ELECTRIC COMPANY, it is reported, has secured the rights to manufacture under the Reidler-Stumpf turbine patents in this country.

THE FAHNESTOCK TRANSMITTER COMPANY has removed its headquarters to 132 Havemeyer Street, Brooklyn, near the entrance of the new Williamsburg Bridge.

JOS. H. THOMPSON, JR., has established offices at No. 11 Broadway, New York, for buying, selling and exchanging electrical and steam machinery and appliances of every description.

THE BURT MANUFACTURING COMPANY, Akron, Ohio, recently received an order from the Russian Government for six Cross oil filters, which is the tenth order that has been received from Russia.

THE SHEPHERD ENGINEERING COMPANY, Franklin, Pa., has located its Boston branch office in the new Oliver Building, at the corner of Oliver and Milk Streets, in charge of Mr. W. N. Clifford.

WESTERN ELECTRIC COMPANY'S NEW PLANT.—Contracts for additional buildings in connection with the Western Electric Company's plant at Hawthorne, Ill., have been let. These, it is estimated, will cost about $100,000.

THE LUNKENHEIMER COMPANY, Cincinnati, Ohio, has a very comprehensive display of its line of steam specialties in Machinery Hall at the Louisiana Exposition. The exhibit is No. 5-G in block 26.

THE JONES FAN & MOTOR COMPANY has been incorporated in New York with a capital stock of $2500. The directors are C. D. Marsh, L. A. Landau and James Jones, Jr., all of New York.

ALLIS-CHALMERS-BULLOCK, LTD., is the style of the Canadian organization of the Allis-Chalmers and Bullock Electric Manufacturing Companies of this country. The works and principal offices of the Canadian company are in Montreal.

THE AMERICAN PUSH-BUTTON TELEPHONE COMPANY, New York, announces that it has been authorized by the court to change its legal name to Anders Push-Button Telephone Company, the authorization taking effect on and after May 7, 1904.

THE TALMONT ELECTRIC ENGINEERING COMPANY has been incorporated in New York with a capital stock of $5000. The officers are Adolph Talmont, president; G. D. Roedelsberger, vice-president, and M. J. Hornthal, secretary and treasurer.

A CORRECTION.—In this department of last month's issue it was stated that Mr. George L. Crosby had been appointed district representative for the Western Electrical Instrument Company at Cleveland. This should have read Weston Electrical Instrument Company.

THE WILLIAM TOD COMPANY, of Youngstown, Ohio, has established a branch office at 29 Broadway, New York, under the management of Mr. Geo. F. Woolston, formerly of the well-known firm of Woolston & Brew. The Tod Company is building full lines of Corliss heavy duty engines, pumping engines, blowing engines and gas engines.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has issued a cordial invitation to the electrical fraternity at large to visit and use its offices as headquarters during the World's Fair period. The company will provide stenographic facilities and other conveniences for visiting friends.

HOLMES METALLIC PACKING COMPANY, Wilkesbarre, Pa., reports that its fiscal year just closing has been very prosperous and that its orders are increasing daily under the able management of Geo. D. Rollins. The company contemplates increasing its facilities for turning out some of its most popular metallic packings.

JOSEPH E. LOCKWOOD, Detroit, Mich., has been appointed Michigan sales agent for the Bullock Electric Manufacturing Company. Mr. Lockwood is one of the pioneer electrical supply men of the country, and is well known throughout the electrical field all over the United States. Mr. Lockwood will also act as representative for several other interests.

JAMES S. BARRON & CO., New York, state that in spite of the fire which recently destroyed their building and all the contents, amounting to $185,000, they have taken new quarters at 339 Greenwich Street, where they will remain until the completion of their new building on the old site, which will be about May, 1905. The damage was fully covered by insurance.

MOLONEY ELECTRIC COMPANY, St. Louis, Mo., is an excellent example of the value of specilization. Having decided on the exclusive manufacture of alternating-current transformers, the company has devoted its entire energies and talent to that subject, and the result has been a remarkable growth in its business. The company has just moved into a new factory having an aggregate floor space of over 35,000 square feet devoted entirely to the manufacture of transformers.

THE AUTOMATIC ELECTRIC COMPANY, of Chicago, is now installing 4,000 automatic telephones and complete switching equipment for the Home Telephone Company, of Los Angeles, Cal., and 1,200 instruments for the Auburn Telephone Company, Auburn, N. Y. The company has also received orders for an exchange equipment for San Diego, Cal., of 1,200 automatic telephones and one at Lewiston, Me., of 1.500.

EWING-MERKLE COMPANY, St. Louis, Mo., has issued a very convenient map of the World's Fair Grounds. The map is 8x12 inches in size and folds into a neat envelope which can be carried in the vest pocket. It shows the location of all the buildings and features of the Exposition and is provided with an index which enables one to find any building or feature without delay. Copies are sent free on application.

THE DERRY-COLLARD COMPANY, New York, is making very convenient sketching pads for isometric perspective drawings. The pads are ruled like cross-section paper, and have in addition diagonal lines ruled at an angle of about 30 degrees with the horizontal. The pads have 50 sheets each and are made in two sizes, 6x9 ins. and 9x12 ins. The paper is also supplied in loose sheets 12x18 ins.

THE S. H. COUCH COMPANY, Boston, Mass., recently closed several important contracts for telephone equipment, among which may be mentioned the La Fayette Hotel, Portland, Me., where 140 instrumetns will be installed in connection with a common-battery switchboard of the company's new target type. Common-battery instruments have also been sold to the Worcester (Mass.) City Hospital and the Hartford Carpet Corporation, Thompsonville, Conn.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., are represented at the Louisiana Exposition by a handsome building facing the Plaza in the Model Village. The lower floor of the building contains an exhibit of the plans and methods of the schools, with specimens of the work done by students, while the upper floor contains a reading room, writing room and post office for the use of students of the schools and their friends.

THE WATSON-STILLMAN COMPANY has removed its offices and stock of goods to 46 Dey Street, New York City, and all machinery to the new works at Aldene, Union County, N. J., where the company will have ample room to expand. The works are located at the junction of the Lehigh Valley Railroad, the Baltimore & Ohio Railroad, and on the low-grade connection between the Lehigh Valley Railroad and the Central Railroad of New Jersey, with a track 1,000 feet long in the company's yard.

THE NERNST LAMP COMPANY has established a branch office at 537 Schofield Building, Cleveland, Ohio, in charge of Mr. J. C. Wright. The Cleveland office will carry a full stock of Nernst lamps and renewal parts. The company reports a rapidly growing business in the New England district. Large orders were received recently from the Saco & Pettee Machine Shops, Biddeford, Me., for three-glower lamps, and from the Arlington Mills, Lawrence, Mass., for 600 lamps of the 44-watt type. The latter is the second lot of Nernst lamps ordered by the Arlington Mills.

CHAPMAN VALVE MANUFACTURING COMPANY, Indian Orchard, Mass., suggests that those who attend the convention of the National Electric Light Association at Boston, Mass., will undoubtedly find a visit to the K Street Station of the Edison Electric Illuminating Company very interesting. Here the pipe lines feeding superheated steam to the steam turbines are fitted with Chapman valves designed especially for that service. In the same station may also be seen Chapman valves equipped with electric motors for quick, easy and certain operation. Both of these ideas are a new departure in power-house equipment and represent the very latest improvements in modern practice.

ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, has a very extensive exhibit at the St. Louis Exposition in block 20, Electricity Building. A conspicuous feature of the exhibit is a map, 30 feet high and 45 feet wide, on which is shown the distribution of Chloride accumulator installations throughout the United States. The character of each installation is indicated by an illuminated glass lens. Specimens of Chloride accumulators, ranging from the smallest laboratory cells up to the 61-H type, are shown, and a complete exhibit of the Exide automobile battery is also shown. In another section of the exhibit there are shown five types of switchboards with end cell switches, storage battery recording instruments, etc., and there is a complete operating installation of Chloride accumulators for railway service in a model battery house.

WHITNEY ELECTRICAL INSTRUMENT COMPANY (Machado & Roller, general agents) announce that Judge Lacombe, of the United States Circuit Court for the Southern District of New York, on May 9 denied the application of the Weston Electrical Instrument Company for a preliminary injunction against the Whitney Company and Machado & Roller in the suit for infringement of Weston patent No. 392,387, which was recently sustained against other instrument manufacturers. The case was argued at length by Messrs. Kenyon & Kenyon on behalf of the Weston Company and by Mr. C. V. Edwards on behalf of the Whitney Company. Machado & Roller, the general selling agents of the Whitney Electrical Instrument Company, announce that, in addition to this decision, another suit brought by the Weston Company against the Whitney Electrical Instrument Company and themselves on Weston patent No. 446,489 was dismissed upon final hearing by the Court in October last. The defendants are naturally elated over these decisions.

THE STANLEY UNDERGROUND CABLE COMPANY, Pittsburg, and the **McROY CLAY WORKS,** Brazil, Ind., have an interesting joint exhibit at the St. Louis Exposition in section 3 of Electricity Building, which is near the northwest entrance of that building. The exhibit shows a cross-section of a conduit having 72 ducts with a man-hole at each end, one man-hole being complete with a cover and the other open. A trench extends the full length of the conduit, allowing inspection of the method of laying, the general construction of the man-holes, etc. In one man-hole a capstan is rigged up for drawing in cables, and a rope extends from the capstan to the end of a cable in the conduit, the cable being drawn through the conduit from a reel in the other man-hole. Cables extend from the man-holes to distributing poles, showing the methods of distribution for different classes of electrical work. The Standard Underground Cable Company shows also samples of its extensive line of cables and appliances enclosed in handsome cases, and the McRoy Clay Works exhibits individually piles of clay as it comes from the ground and the various processes to which it is subjected.

CENTRAL STATION NEWS

ALABAMA.

BIRMINGHAM.—Extensive improvements are now under way at the plant of the Birmingham Railway, Light & Power Company; these include the installation of new boilers and a new 1500-kw. alternator. The sub-station, at Brighton, has been completed and machinery installed for converting high-tension alternating current to low-voltage direct current. This plant will supply current for lighting purposes in Brighton and also furnish power for two car lines running to Bessemer, thus saving the loss which now occurs by reason of the long circuit and low voltage of the supply. It is also stated that in the near future provision will be made to supply Bessemer with current from the same source, or from a converting station located in that city.

ARIZONA.

MORENCI.—The Arizona Copper Company is interested in the construction of an electric plant on Blue River to furnish light and power for the mining camp and town.

TEMPE.—The Tempe Pumping Company has been organized to pump approximately 450,000 gallons of water per minute for irrigation purposes; the plan being to pump 11,250 gallons of water per minute in the power plant and to transmit electric power to five sub-stations for pumping the remainder. Electricity will also be generated for industrial and lighting purposes. The power plant, which is to be a steam plant exclusively, is now in course of construction and will probably be in operation by July 15.

ARKANSAS.

LITTLE ROCK.—In his annual message, the Mayor recommended installing 40 more electric lights and a new boiler room for the electric light plant; he also said that all wires should be placed underground.

CLARKSVILLE.—Mr. E. T. McConnell has been granted a thirty-year franchise for an electric light plant to be completed in six months. It is understood that Mr. McConnell will begin the erection of the plant immediately.

CALIFORNIA.

SAN DIEGO.—The San Diego Gas & Electric Light Company is planning to extend its pole line to National City.

LODI.—The Lodi Electric Works have been absorbed by the Northern San Joaquin Electric Company.

LOS ANGELES.—The San Gabriel Electric Company has leased the plant of the Sierra Power Company.

ALTURAS.—The Alturas Electric Light & Power Company, with a capital stock of $20,000, has been incorporated by D. E. Mulkey and I. W. Gibbons.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

LEMOORE.—It is expected that a 75-h.p. engine and a 50-kw. alternating-current dynamo will be added shortly to the equipment of the municipal electric light and water works.

SAN FRANCISCO.—The Pacific Power Company is offering for sale the machinery of its electric power plant at 23 Stevenson Street, including two engines, four boilers, three generators and auxiliaries.

RED BLUFF.—It is understood that the Northern California Power Company will install at the gas works in this city a large electric plant to generate electric current for use in cases of emergency.

LOS ANGELES.—The Los Angeles Gas & Electric Company was recently incorporated by W. B. Cline, William M. Van Dyke, William Baurthyte and others. The company is capitalized at $5,000,000.

SAN FRANCISCO.—At the annual meeting of the Board of Directors of the San Francisco Gas & Electric Company, the article of incorporation were amended to increase the number of its members from 11 to thirteen.

OAKLAND.—A movement is on foot to have the electric wires on Telegraph Avenue placed under ground, and it is probable that the work will be undertaken by the electric companies in the near future.

CLOVERDALE.—The Riverside Water Company will, within a short time, install an electric motor and utilize electricity from the Cloverdale Light & Power Company's plant for the purpose of pumping water.

QUINCY.—Mr. J. D. Goodwin recently incorporated the Quincy Water & Power Company with a capital stock of $50,000. It is the intention of the company to improve the water works and to install an electric power plant.

MENDOCINO.—The Mendocino Electric Light & Power Company is now in full possession of the old Mendocino Lighting Company's plant. Mr. J. Grindle is president of the company and Mr. Albert Brown, secretary.

WATSONVILLE.—Press reports state that the Big Creek Power Company, of Santa Cruz, will purchase property in this city as a site for a plant to furnish the local circuit with electric power; about $100,000 will be spent in improving the service here.

CHICO.—The Valley Counties Power Company contemplates doing considerable work on its Nimshew plant the coming summer, and probably another line will be run to this city to be used, especially for the purpose of conveying power in case of emergencies.

OAKLAND.—Lightning recently struck one of the wires of the Standard Electric Company, with the result that the interior of the company's substation at Elmhurst was demolished, involving a loss of about $3000. Mr. W. H. Pollard is superintendent of the station.

MADERA.—Mr. F. A. Krogh, president of the Madera electric light works, is making arrangements for a new brick building as an addition to the present plant, which will be used to furnish power for a cold storage and ice plant to be erected in the fall. The new equipment will include a boiler and engine. The lines will be extended to parts of the town not heretofore lighted.

ALAMEDA.—The demand for electric power for day use is rapidly increasing here, and the Electric Light Committee of the City Trustees is inspecting the local plant with a view to installing day power for local consumption. Whether this will be generated at the municipal works or purchased from an outside company and distributed by the city is yet to be decided.

BAKERSFIELD.—The Power, Transit & Light Company, with a paid in capital stock of $2,500,000, is a consolidation of the Power Development Company, Bakersfield Gas & Electric Light Company, and the Bakersfield & Kern Electric Railway Company. Lighting current is supplied to both Bakersfield and Kern, and the company's equipment includes turbines with a total capacity of 2175 horse-power.

SACRAMENTO.—The American River Electric Company has secured permission from property owners between Folsom and Sacramento to erect an electric transmission line across their lands. The line is owned by A. Flieshhacker & Co., of San Francisco. The company has also secured a franchise to run its lines through Sacramento County and will shortly apply for the necessary privileges in Sacramento City.

LOS ANGELES.—The California Gas & Electric Corporation has cut up its great system into divisions; this section will be known as the Nevada County Division. A number of changes have resulted, which have been given out officially as follows: Mr. John Calvert, of Grass Valley, is manager of the distribution of power at the Grass Valley sub-station, and Mr. A. Rickard is manager of the hydraulic department; the Nevada City power house is under the management of Mr. Frank Nelson, and the commercial department is in charge of Mr. John Werry.

SAN FRANCISCO.—The Northern California Power Company is a consolidation of the Keswick Electric Power Company, Redding Electric Light & Power Company, Redding Water Company, Redding Gas Company, Red Bluff Gas Company, Tehama Electric Company, and Bellevue Irrigation Company. The company's capital stock is $2,000,000, and the following are its officers: President, Mr. H. H. Noble; vice-president, Mr. James Coffin; secretary, Mr. E. Whaley; manager, Mr. E. V. D. Johnson. Current is supplied to 108 arc lamps and 12,000 incandescent lights.

COLORADO.

SILVERTON.—The Town of Silverton is building about two miles of new line and 25 series arc lamps are to be installed for street lighting.

GRAND JUNCTION.—The Grand Junction Electric & Gas Company reports that it has doubled the capacity of its plant during the last three months.

GLENWOOD SPRINGS.—The Colorado Power & Irrigation Company, of Denver, has purchased a water right about twelve miles from this place on Grand River.

SALIDA.—The Chaffee County Electric Light, Power & Railway Company was recently incorporated with a capital stock of $500,000, the purpose of the company being to furnish electricity for light and power purposes and to construct a street railway line in Salida and its suburbs. The company will also construct lines to the towns of Buena Vista, Turret and Poncha Springs. Mr. T. E. Mason, of Des Moines, Iowa, is one of the directors.

CONNECTICUT.

SOUTH NORWALK.—The municipal plant of this city is extending its outside lines.

NORFOLK.—The installation of a new electric light plant is being considered by the town council.

BRIDGEPORT.—The large generator recently installed at the power house of the Connecticut Railway & Lighting Company stood the test to which it was subjected and is now ready for operation with the other equipment of the power station.

WOODBURY.—The Woodbury & Southern Electric Railway Company is being organized at this place, with a capital stock of $15,000 fully paid in. The company will furnish electricity for lighting both Woodbury and Southbury. The officers are: Mr. James Huntington, president; Mr. F. F. Hitchcock, vice-president; Mr. E. S. Boyd, secretary and manager.

MERIDEN.—The transformer plant which the Meriden Electric Railway Company has been erecting at Hanover Park has been completed and is now in operation. Under the new arrangement the power to operate the local trolley system will be transmitted from the power station at Berlin, a distance of nine miles. The new system will double the power available for the trolley service. The old power plant, it is said, will be kept in readiness for use in cases of emergency.

DANIELSON.—The People's Electric Light & Power Company, of which Mr. E. J. Walcott is superintendent, is making important additions to its plant. Two new dynamos capable of supplying 3000 lights each will be installed, also another boiler, and a new stack 100 feet high will be erected. This will more than double the present capacity of this plant. The company is also engaged in extending its line to Moosup, whence it will be continued to Central Village and Wauregan.

DISTRICT OF COLUMBIA.

WASHINGTON.—The Potomac Electric Power Company will, in the course of the coming summer, place under ground its 73,820 feet of overhead wires.

WASHINGTON.—Messrs. Edward S. Duvall, Jr., Warren Cochran and William T. Duvall are the incorporators of the Sitka Water & Light Company which recently filed articles of incorporation here. The capital stock is $20,000.

FLORIDA.

PALATKA.—The council has under consideration a proposition made by Mr. G. L. Bailey, offering to sell the gas works and electric lighting plant to the city for $60,000, he to take $30,000 worth of 5 per cent bonds at par as part payment.

GAINESVILLE.—The Gainesville Gas & Electric Light Company, which began operation early this year, has secured the city contract for supplying current to 14 arc lamps of 1200 candle-power and 45 incandescent lamps of 32 candle-power. Mr. George I. Doig is superintendent of the plant.

JACKSONVILLE.—It has been decided to install a new 500-kw. turbine-generator set in the city electric light plant, in order to meet the increased demand for lights. The turbine will be worked condensing at 150 lbs. steam pressure, and the generator of the set is to be a three-phase 60-cycle 2300-volt machine.

WEST PALM BEACH.—The East Coast Electric Light, Power & Ice Company was recently organized with a capital stock of $100,000, all paid up. Mr. Joseph Jefferson, Buzzard's Bay, Mass., is president; Mr. G. G. Strohm, vice-president; Mr. A. R. Beaujin, secretary, manager and superintendent. The company is supplying only lighting current at present.

GEORGIA.

THOMASVILLE.—The town authorities are considering the construction of water works and an electric light plant.

BLAKELY.—The water and electric light plant owned and operated by the city is reported to have been destroyed by fire April 15.

BLUE RIDGE.—The Blue Ridge Electric Light & Power Company, which began operations last year, expects to enlarge its plant in the near future.

THOMSON.—At a mass meeting held recently a system of water works and an electric light plant were agreed upon. The cost of constructing the works and plant is estimated at $25,000.

MILLEDGEVILLE.—The present officers of the Milledgeville Electric Light Company are reported to be as follows: President, Mr. Samuel Evans; secretary and treasurer, Mr. Lewis Andrews; manager and superintendent, Mr. Charles F. Hour; chief engineer and electrician, Mr. J. W. Marchman.

IDAHO.

BOISE.—The Inter-State Electric Company is arranging to construct a tunnel and a power plant on Snake River. The proposed plant will have a capacity of 50,000 horse-power.

POST FALLS.—The Washington Water Power Company is about to install a large power plant of from 8000 to 10,000 horse-power at this point. The plant will furnish power to Post Falls, and also to the Cœur d'Alene electric road.

SAND POINT.—The Sand Point Electric Company expects to install this fall a series alternating-current arc light system to take the place of the present multiple system. A 150 horse-power engine will also be added to the equipment.

ILLINOIS.

BLOOMINGTON.—The Union Gas & Electric Company states that it is not now operating its central station.

BERWYN.—The village of Berwyn contemplates extending the service of its electric light plant to include residence lighting.

TABLE GROVE.—A $4000 bond issue was recently voted for by the citizens, to take over the electric light plant or to install a new one.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

NEVADA.—The contract for the extension of its power station has been let by The Nevada Electric Company, also for the new electrical apparatus to be installed therein.

SAINT ANNE.—The plant of the Saint Anne Light & Water Company is now being operated by Trowbridge, Niver & Co., of Chicago, Ill. Mr. F. A. Flint is superintendent.

BATAVIA.—It is proposed to install a new air compressor at the power house of the municipal plant, and bids for furnishing the same will be received May 21.

GIRARD.—A larger alternating-current generator is needed in the plant of the Girard Electric Light Company, and it is expected that such a machine will be installed before very long.

MARSEILLES.—The property of the Marseilles Water & Light Company has been purchased by Mr. W. D. Boyce, who also owns the Marseilles Land & Water Power Company and now controls all the light and water franchises in the town.

CHICAGO.—Bids are wanted May 3 for furnishing the city with 50,000 feet of No. 6 rubber-covered lead-incased electric light cable and 6000 feet of 7-conductor (No. 16 B. & S. gauge) rubber-covered lead-incased fire alarm cable.

CARTHAGE.—The capital stock of the Carthage Electric Light & Power Company has been increased from $20,000 to $50,000, and the name of the company changed to Carthage Electric Light & Heating Company.

ELGIN.—Recent reports state that the Aurora, Elgin & Chicago Power Company has been purchased from the Aurora, Elgin & Chicago Railway by The Fox River, Light, Heat & Power Company, of this city.

PANA.—Mr. Robert Johns, successor to the Pana Modern Electric Light, Power & Street Railway Company, has also acquired the plant of the Consumers' Electric Light Company and consolidated the two companies. Mr. A. M. Read is superintendent and chief electrician.

MT. STERLING.—The Mt. Sterling Electric Light & Power Company has been making improvements at its power house, preparatory to installing a new 150 horse-power engine. The power house has been enlarged and it is estimated that the total cost of the improvements now under way will be about $3000.

FREEPORT.—Articles of incorporation have been filed by The Pecatonica River Power Company with a capital of $5000. It is the purpose of the company to operate electric lighting, railway and power plants. The incorporators are: Henry B. Witte, Joseph H. Vincent and Charles B. Courtney.

QUINCY.—The Quincy Gas & Electric Company, which is a consolidation of the Quincy Gas Light & Coke Company, the Empire Light & Power Company and the Thomson-Houston Electric Light & Power Company, has also absorbed the Quincy Steam Heat & Electric Company. Mr. George M. Massen is chief engineer for the company.

HOOPESTON.—The Hoopeston Electric Light & Heating Company is supplying current for operating the new electric pumping system which has been installed at the Hoopeston Water Works. There have been erected at the pumping station a compressor pump with a capacity of 300 gallons per minute, which will be driven by a 40 horse-power electric motor, and a triplex pump with a capacity of 25,000 gallons per hour, to be driven by a 30 horse-power motor.

INDIANA.

MADISON.—Mr. B. Spratt has been appointed chief engineer for the Madison Light & Railway Company.

WINAMAC.—Mr. G. F. Agnew is now general manager and superintendent of the municipal light and water plant.

NEW HAVEN.—The City Council has decided to construct an electric light plant, and bids for the same are wanted May 24.

MUNCIE.—The Muncie Light Department is rebuilding its plant, which will be housed in a new building and equipped with new machinery.

MARION.—The contract for the additional machinery to be installed in the city electric plant has been let to the Westinghouse Company.

PERU.—The Indiana Hydraulic Company, of which Mr. Jerome Herff is president, has about completed its plans for the construction of a dam, an electric power plant and an electric railway to run between Vincennes and West Baden.

MISHAWAKA.—The Mishawaka Woolen Mills recently installed another electric motor of 200 horse-power. The factory is now using 950 horse-power generated by electricity from the Hen Island power station, which is also supplying the company with electricity for lighting purposes.

SOUTH BEND.—The South Bend Electric Company has in course of construction a sub-station in South Bend, from which will be distributed the power obtained from the Irvin Branch dam of the St. Joseph & Elkhart Power Company and the Buchanan dam of C. A. Chapin.

TERRE HAUTE.—The new power house which is being erected here by the Terre Haute Electric Company is to be completed by next fall. It is understood that orders have been placed for all the machinery and the boilers are now ready for shipment.

NOBLESVILLE.—In regard to the city lighting contract for a period of ten years, it is reported that the bids received on April 18 were only two in number and were not opened. Bids will again be received on June 15 for lighting the city for ten years.

KOKOMO.—The Kokomo, Marion & Western Traction Company has in course of construction a new power plant to cost $150,000. It will be equipped with direct-connected units and is expected to be ready for operation by July 1. The company is also building an electric railway line from Kokomo to Marion, of which ten miles is now in operation, the balance to be completed by August 1.

VINCENNES.—The Vincennes Electric Light & Power Company, which was consolidated with the Citizens' Gas Light Company, is now controlled by E. M. Deane & Co., Grand Rapids, Mich. The officers are as follows: President, Mr. E. M. Deane, Grand Rapids; vice-president, Mr. Charles Bierhaus, Vincennes; secretary, Mr. F. S. Deane, Grand Rapids; treasurer, Mr. D. Smith, Grand Rapids; manager, Mr. H. B. Wales, Grand Rapids; superintendent, Mr. A. W. Frund, Vincennes; chief engineer, Mr. John J. McClure.

IOWA.

LOGAN.—The Logan Electric Light Company is adding a new boiler to its plant equipment.

BURLINGTON.—A special election is to be held to vote for a bond issue of $27,000 for the construction of an electric lighting plant.

MARION.—The Marion Light, Heat & Power Company is installing new generators at its plant, and is also adding a number of new street lights.

LEON.—The municipal electric light plant at this point will be sold by the city. Mr. I. N. Beard is chairman of the committee to effect the sale.

SPIRIT LAKE.—Mr. J. B. Thompson is superintendent and chief electrician of the municipal light and power plant, and Mr. W. H. Alton is chief engineer.

KEOKUK.—A bill has been prepared and presented to Congress, granting to the Keokuk & Hamilton Water Power Company the right to construct and maintain for the improvement of navigation and development of water power a dam across the Mississippi River; also to construct and maintain power stations for the generation, use and transmission of electric energy and power.

MOULTON.—The Moulton Electric Light Company was recently consolidated with the La Plata (Mo.) Electric Light Company under the style of the former company. The paid in capital stock is $12,000. The following are the officers: President, Mr. James Bolton, Moulton; secretary, Mr. R. W. Bolton, Alexis, Ill.; treasurer, Mr. George Bolton, Moulton; chief electrician, Mr. Sidney Boulton, La Plata. The company has the city lighting contract for both Moulton and La Plata.

KANSAS.

CHANUTE.—Mr. Fred L. Krueger is superintendent of the municipal electric light plant, which has been in operation about six months. The plant is said to have cost $40,000.

KENTUCKY.

PADUCAH.—The Board of Public Works has decided to improve the electric light plant.

PRINCETON.—The Princeton Electric Light & Power Company has filed articles of incorporation with the Secretary of State, stating the capital stock to be $25,000.

FT. THOMAS.—Bids are wanted May 31 for wiring buildings; furnishing and installing watt and voltmeters, transformers, arc lamps, and other electric fixtures; erecting necessary pole lines on the reservation, and furnishing the necessary current for electric lighting at this post.

LOUISIANA.

FRANKLIN.—The plant of the Franklin Electric Light & Power Company, Ltd., is now owned and operated by the city. Mr. J. C. Lewis is superintendent.

NEW ORLEANS.—The Consumers' Electric Company states that it has secured a site for the erection of a lighting and power plant which it is proposed to construct immediately, to cost probably $1,000,000.

GRETNA.—The Jefferson Ice & Electric Light Company, which is operating at present a lighting plant, contemplates installing a plant sufficiently equipped to supply lighting current for the towns of Gretna and McDonoghville.

BATON ROGUE.—A charter has recently been granted to Messrs. C. K. Kretz, E. F. Wieck and Turner Bynum for the Capital Light & Power Company, Ltd., with a capital stock of $25,000. Mr. Kretz is president of the company, and Mr. Wieck, secretary and treasurer.

LAKE CHARLES.—The Lake Charles Ice, Light & Water Works Company is making extensive improvements in its plant, comprising the addition of a 300-kw. generator and a 100-light station transformer to its equipment. The company is also installing fifty alternating-current series arc lamps to replace the alternating-current incandescent lights in use heretofore.

NEW ORLEANS.—The New Orleans Railway Company has been awarded a ten-year franchise, dating from September 30, 1905, for lighting the public highways, streets, squares and parks of the city with electricity and for furnishing electric energy for public buildings for the operating of arc and incandescent lamps, motors, pumps, fans, elevators and other public purposes. The franchise calls for the lighting of 476 underground district circuits and for 2151 overhead district circuits. It also includes 200,000 kilowatts of power. The company will receive $200,879 per annum for the service.

MAINE.

DOVER.—The Sebec Lake Railway Company is negotiating for the lease of the surplus water power at the dam of the Dover and Foxcroft water district, for the purpose of operating a power station.

OAKLAND.—The Oakland Electric Company is contemplating the development of a second station involving an expenditure of $100,000. The proposed plant will have a water power capacity of 15,000 horse-power and 750 horse-power steam.

WATERVILLE.—The Ft. Halifax Power Company has been organized at Waterville for the purpose of constructing electric light and power plants in Benton and Winslow. The capital stock of the company is $250,000, and Mr. Harvey P. Eaton, of this city, is president and treasurer.

BAR HARBOR.—The Bar Harbor & Union River Power Company, which is a consolidation of the Bar Harbor Electric Lighting Company, the Ellsworth Electric Ice Company and the Ellsworth Water Company, is now furnishing current for lighting purposes to Seal Harbor and Northeast Harbor.

PITTSFIELD.—On May 3 the Pittsfield Electric Light & Power Company sustained a heavy loss by fire amounting to $50,000, only partially covered by insurance. The building was completely destroyed, but the engine, dynamo and boilers were saved. The saw mill, which was

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

run in connection with the plant, was also destroyed. A temporary structure will be erected at once for the lighting system, but it is not yet known whether the entire plant will be rebuilt or not.

MARYLAND.

BALTIMORE.—Bids will be received for installing and maintaining electric lights in Druid Hill Park.

MASSACHUSETTS.

MANSFIELD.—Mr. James E. Arthur is reported as manager of the municipal lighting plant of this place.

ROCKLAND.—Most of the machinery for the sub-station of the street railway company, in course of erection here, has been received and is being installed in the plant.

HOLYOKE.—At a recent meeting of the Board of Aldermen, an order fixing the salary of the manager of the municipal lighting plant went to a first reading by vote of 10 to 9.

SPRINGFIELD.—The new equipment being installed at the power station of the United Electric Light Company comprises a 1000-kw. four-pole generator, direct-connected to a steam turbine of corresponding capacity with a speed of 1800 r.p.m.

WESTFIELD.—Much of the material for the new electric power plant being constructed here has arrived, and the work of stringing the wires has begun. It is expected that the plant will be ready for operation by the middle of July.

CHARLESTOWN.—The two buildings in course of erection at the Charlestown Navy Yard are nearly completed and will be ready within a short time. It is planned to concentrate all of the workshops and offices in the larger building, while the other will be occupied entirely by the large power plant.

INDIAN ORCHARD.—The additions, in course of construction at the plant of the United Electric Light Company here, are nearing completion, and new machinery is to be installed which will increase the capacity of the plant from 2850 to 3800 horse-power. The addition to the building is a one-story brick structure 50 x 40 feet. A 600-kw. generator is to be installed and an underground cable will be run to the new motor-house of the Indiana Orchard Company's mills, which will use about 200 horse-power. Three hundred horse-power will also be conveyed to the Fiberoid Company's plant, which is to be in operation soon.

MICHIGAN.

EATON RAPIDS.—The citizens have voted to issue water and lighting bonds.

BANGOR.—The village of Bangor is now operating its own electric light plant.

DETROIT.—The Public Lighting Commission is making arrangements to install 250 street lights in the city.

WEST BAY CITY.—The citizens recently voted to issue $60,000 for improvements to the water, light and sewerage systems.

BROWN CITY.—Mr. A. B. Granger has been appointed manager of the municipal electric lighting plant, which began operation last year.

DEXTER.—Since the first of the year, the plant of the Dexter Electric Light & Power Company has been owned and operated by the village. Mr. G. M. Hicks is superintendent and chief engineer.

KALKASKA.—The Kalkaska Electric Light Plant, Saw & Planing Mill has been succeeded by the Kalkaska Electric Light & Power Company, of which Mr. A. E. Palmer is secretary.

MANISTEE.—The Manistee Gas & Electric Company is changing over from open arc lamps to enclosed alternating-current series lamps for street lighting.

BOYNE CITY.—The Boyne City Electric Company contemplates increasing its water power and will add a three-phase alternating-current generator to its plant equipment.

ZEELAND.—The Zeeland Water & Light Station will probably install a 250-volt direct-current marine set before next winter to be used after midnight.

MOUNT PLEASANT.—The present officers of the Mount Pleasant Electric Company are as follows: M. O. Newberry, president; A. E. Newberry, vice-president; W. F. Newberry, secretary and manager.

KALAMAZOO.—The Kalamazoo Valley Electric Company, which operates three power plants between Allegan and Jackson, is contemplating the construction of a fourth plant to cost about $200,000.

GRAND LEDGE.—The Grand River Power Company has secured an option on land along the river near Beutch Bridge for electrical purposes. Engineer H. A. Sprague, of Corunna, is said to be interested in the enterprise also.

CENTREVILLE.—The plant of the Centreville Water & Electric Light Company, which has been idle for the past month on account of the damage done by the high water, is again in operation. The town has been in darkness in the meantime.

BOYNE CITY.—The Boyne City Electric Company, which began operation this year, has been purchasing steam power for the operation of its plant. It is now intended to install water power equipment capable of developing 300 horse-power, and a three-phase alternating-current generator will also be added to the plant. Mr. M. W. Swift is superintendent.

ALLEGAN.—Messrs. S. Baker, H. A. Delano, George E. Delano, of Otsego, and F. M. Van Auken, of Allegan, have purchased the plant of The Allegan Light & Power Company, for which they are understood to have paid $15,000. It is expected that several improvements will be made in the equipment, comprising two water wheels, a 300-h.p. engine, boilers, shafting, etc.

MARQUETTE.—Notwithstanding its charges for service are the cheapest in the state, it is reported that the municipal electric lighting plant shows a net revenue of nearly $13,000 for the fiscal year just closed, after full allowance for interest, depreciation, maintenance and a bond payment of $5,000 made from the treasury. The total income was $36,000 and the total operating expenses for the year $18,400. The number of residences lighted is 546 and business houses 282, a total of 828 patrons.

GRAND RAPIDS.—The Grand Rapids Edison Company is a consolidation of the following companies: Edison Light Company of Grand Rapids, Grand Rapids Electric Light & Power Company, Peninsular Light, Power & Heat Company, The Lowell Water & Light Company and the West Michigan Electric Company. The officers of the company are: President and general manager, Mr. Daniel McCool; vice-president, Mr. McGeorge Bundy; secretary and treasurer, Mr. Thomas F. Bechtel; general superintendent, Mr. A. F. Walker; chief engineer, Mr. Waldo Francisco.

ANN ARBOR.—The Michigan Milling Company is preparing to install an electric plant to furnish power to two steam mills; current will also be supplied for lighting the mills. The company owns two other water powers within five miles of Ann Arbor, both of which will probably be utilized for electric power purposes also, making a total capacity of 2000 horse-power. The officers of the company are as follows: Mr. H. S. Dean, president; Mr. W. C. Stevens, vice-president; Mr. Allmendinger, secretary and treasurer, and Mr. N. J. Kyer, manager and purchasing agent.

MINNESOTA.

BREWSTER.—The Village Board is considering the construction of an electric light plant.

PERHAM.—It is reported that bids are wanted for a 200-kw. dynamo, a 250-h.p. engine and a 165-h.p. boiler for the electric plant here.

WARREN.—Mr. W. Haney is now superintendent and chief electrician of the Warren Electric Light & Water Works.

JANESVILLE.—A bond issue will probably be voted on for the construction of an electric light plant and water works which it is estimated will cost $22,000.

CANNON FALLS.—The plans of the Cannon River Electric Power Company for the construction of its power plant have been completed and the contracts will be let at once.

DULUTH.—The Duluth General Electric Company, with a paid in capital stock of $117,000, is a consolidation of the Commercial Light & Power Company and the Hartment General Electric Company. Mr. Thomas Marks is superintendent.

FORT SNELLING.—The equipment of the plant at Fort Snelling, which is owned by the United States Government, will probably be enlarged and the installation of new engines and generators is contemplated; the boiler capacity will also be increased.

MONTEVIDEO.—The incorporation of the Montevideo Electric Light & Power Company, which was referred to in last month's issue, is now an accomplished fact. The capital stock is placed at $60,000 and the incorporators are: Messrs. E. H. Sorlein and Olaus Lende, of Granite Falls, and E. A. Aspines and Lyndon A. Smith, of this place.

MISSISSIPPI.

STARKVILLE.—Mr. J. C. Arnold is now superintendent of the municipal electric light plant.

WOODVILLE.—Bids will be received until June 7 for erecting a system of water works and electric light plant.

CLARKSDALE.—Mr. J. H. Hooks is manager and superintendent of the Clarksdale Water & Light Company.

GREENWOOD.—The citizens recently voted to buy the water, light and sewerage systems at the appraised valuation of $122,586.

COLUMBUS.—Mr. E. W. Waring has been made superintendent of the Columbus Electric Light & Power Company.

INDIANOLA.—The officers of the Indianola Light, Ice & Coal Company are now as follows: President, Mr. W. T. Pitts; secretary and treasurer, Mr. M. L. Pitts; manager and superintendent, Mr. P. H. Williams.

HATTIESBURG.—The Hattiesburg Light & Power Company has closed a contract for $10,000 worth of new machinery and expects to spend more within the next few months in enlarging and improving its plant. Besides the smaller equipment, the order calls for a 500-h.p. engine and a 300-kw. generator. The company is preparing to furnish additional current for commercial lighting purposes and for 150 new street lights.

MISSOURI.

DE SOTO.—Mr. A. T. Vick is superintendent of the Cosumers' Electric Light & Power Company.

UNIONVILLE.—Mr. C. H. Tingley is superintendent of the municipal electric light and water works.

ST. GENEVIEVE.—Mr. Garfield Thomure is now chief engineer of the St. Genevieve Light & Power Company.

BOONVILLE.—Mr. Frederick Dunnavant is chief engineer of the Boonville Electric Light & Power Company.

FARMINGTON.—Mr. O. F. Sessinghaus is now manager of the plant of the Farmington Electric Light & Ice Company.

ST. LOUIS.—Plans for a municipal plant to light by electricity that portion of the city south of Keokuk Street are being considered by the Board of Public Improvements. The plant will probably be situated at the corner of Osage Street and Virginia Avenue. The city is paying at present $59,000 a year for lighting this section by gas.

JOPLIN.—A large electric plant for the purpose of transmitting power to all sections of the mining district of southwest Missouri is to be erected on the banks of Spring River at Lowell, Kans., by Mr. W. J. Sergant, of this city, who has an electric power franchise in Joplin and other cities throughout the mining district. Mr. Sergant has begun the work of building a dam across the river, which is to be 60 feet wide at the base and 12 feet in width at the top. With the river thus harnessed it is said that 700 horse-power can be developed. It will probably be a year before the plant is in operation.

MONTANA.

GLENDIVE.—Mr. Joseph Rice has been appointed chief engineer of the Hughes Electric Light Company.

NEBRASKA.

NELIGH.—The Neligh Mills, of which Mr. S. F. Gilman is the owner, are installing a new dynamo and putting more copper in their lines.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

OMAHA.—The city electrician has recommended the substitution of iron for wooden poles for street arc lamps and the matter is now under consideration.

HUMPHREY.—Mr. Henry Brunning is manager of the electric light plant of the Humphrey Electric Light & Telephone Company. The telephone department is managed by Mr. John Mugg.

ST. EDWARD.—Messrs. D. Hinman and O. H. Flory are proprietors of the electric light and power plant of this city. The operating equipment of the plant consists of a 100 horse-power turbine, two 35 horse-power gas engines and 220-volt direct-current dynamos.

PETERSBURG.—Mr. N. W. Wies, who recently came here from Scribner, has purchased a site in the east part of town and has begun the erection of a building for an electric light plant. Mr. Wies expects to have the plant in operation the early part of June.

BENEDICT.—Mr. W. G. Keeler, owner of the Benedict electric light plant, states that he will have to either put in a larger dynamo to take the place of the present one or install another of the same size as the one now in use, in order to meet the increased demand for service.

HOOPER.—The electric light plant, owned by Mr. William T. Martin, was recently destroyed by fire, leaving the town in almost total darkness. The building will have to be entirely rebuilt, and the machinery was considerably damaged by heat and water. Mr. Martin will rebuild the plant at once.

LINCOLN.—Articles were recently filed with the Secretary of State of Nebraska by the North Platte Electric Light & Power Company, of Colorado, which desires to do business in Nebraska. The company's headquarters are in Denver. The capital stock is $20,000, and the company operates its plants by means of power obtained from the North Platte River.

GALLUP.—The Gallup Electric Light Company was recently organized, with a capital of $50,000, to succeed the Gallup Electric Light & Power Company. The plant equipment of the company consists of three Westinghouse generators, an engine and a boiler. They have the city contract for lighting, and also furnish current for commercial lighting. Gibson, N. M., is lighted by current supplied from this plant.

NEW HAMPSHIRE.

LISBON.—The following are the officers of the Lisbon Edison Electric Light Company: Mr. E. H. Hallett, president; Mr. G. Brummer, vice-president; and Mr. W. W. Oliver, secretary and manager.

CLAREMONT.—Mr. E. C. Baker is now chief engineer of the Claremont Railway & Lighting Company.

BERLIN.—Mr. F. L. Goodnow is now superintendent and chief engineer of the Cascade Electric Light & Power Company.

ALTON.—Mr. Ellsworth H. Rollins is now president of the Alton Electric Light & Power Company, and Mr. Charles H. Davis is secretary and treasurer.

MEREDITH.—The Meredith Electric Light Company is considering a contract with the city to furnish 58 arc lights and 50 incandescent lamps for one year.

NEW JERSEY.

JERSEY CITY.—The United Electric Company of New Jersey, which is now embraced in the Public Service Corporation, has been granted permission to construct subways for electric light, heat and power wires.

TOMS RIVER.—The Toms River & Island Heights Electric Light & Power Company is contemplating adding another unit to its equipment.

WEEHAWKEN.—Bids will be received for furnishing all apparatus, material and labor necessary for the construction of an electric light plant in the sewage station.

BERNARDSVILLE.—The Bernardsville Electric Light Plant has recently placed an order for a new 17 x 18 four-valve engine which will be added to its equipment.

SEA ISLE CITY.—It is reported that the People's Trolley Company is negotiating for the purchase of the Sea Isle City Electric Light, Water & Power Company's plant.

RUTHERFORD.—It is said to be the intention of the Gas & Electric Company of Bergen County to change its transmission lines from the power plan to sub-stations and from 2600 volts two-phase to 6600 volts three-phase.

JERSEY CITY.—The North Jersey Street Railway Company has purchased a large tract of Hackensack River shore front upon which it is proposed to erect a power house at a cost of $400,000 for the buildings and machinery. The new plant, it is said, will furnish power for the entire trolley system east of the Hackensack River and thus do away with many of the smaller power houses. Plans for the new structure are already under way.

NEW YORK.

AKRON.—Mr. H. C. Lewis is now superintendent of the village electric light plant.

SAG HARBOR, L. I.—Bids were received by the village trustees on May 3 for $24,000 electric light bonds.

RICHFIELD SPRINGS.—The president of the Richfield Springs Electric & Power Company is now Mr. M. A. McKee.

PEEKSKILL.—Mr. C. L. Woods has been appointed chief engineer of the Peekskill Lighting & Railroad Company.

ST. JOHNSVILLE.—A new dynamo has been recently installed in the plant of the East Creek Light & Power Company.

BRASHER FALLS.—Mr. B. A. Babcock, owner of the electric plant here, states that he expects to install a new water wheel this summer.

ONEONTA.—Mr. E. E. Arnold, of Providence, R. I., is now president of the Oneonta Light & Power Company, and Mr. John R. Gladding, also of Providence, is treasurer.

CLINTON.—The repairs and additions at the Clinton Electric Light Company's plant are being rushed as fast as possible and it is expected that the plant will soon be ready for operation.

AUBURN.—The Auburn Light, Heat & Power Company, which is controlled by the Electric Company of America, Philadelphia, is to have additional boiler equipment installed at its plant.

ALEXANDRIA BAY.—The village has recently made a new street lighting contract with the St. Lawrence International Electrical Company for an increased number of lights, at a higher price.

FARMER.—The contract for lighting the streets of Farmer has been awarded, and it is expected that an all-night system will be in operation by June 1.

MUNNSVILLE.—Estimates have been completed for the construction of a power plant at Limekiln Falls, near this city. The plant, which will be capable of developing 1000 horse-power, is to cost $45,400.

MIDDLETOWN.—Bids will be received for furnishing 63 arc and 315 incandescent lights of 1200 candle-power and 32 candle-power respectively, for a period of one year from November 1, for lighting the streets every night on an all-night schedule.

MEDINA.—The first penstock and wheel installed at the big dam of the Sweet Power Company were recently tested and found to work in a satisfactory manner. The two remaining penstocks will be put in and the turbines will be ready by the time the full water power has been developed.

SCHENECTADY.—The subway for electric cables, which the Schenectady Railway Company has had in course of construction since October, 1902, is about completed, and it is expected that before fall all the wires will be underground, including the trolley feeding cables, those supplying the sub-stations on the Troy and Albany lines and all the wires supplying lighting current to the city.

ROCHESTER.—The merger of the Rochester Gas & Electric Company, the Rochester Railway Company and the Rochester Light & Power Company, which has been under discussion for some time has at last been consummated. The name of the consolidated companies is to be the Rochester Railway & Light Company. Its capital stock will be $3,000,000 preferred and $6,500,000 of common stock.

HOOSICK FALLS.—At its annual meeting held recently, the Hoosick Falls Electric Company decided to rebuild the dam at its power station and work will be commenced immediately. The following officers were elected for the ensuing year: Frank H. Viele, Worcester, Mass., president; Mr. Derick L. Hall, Hoosick Falls, vice-president; Mr. W. H. Tylee, Worcester, secretary and treasurer, and Mr. Ralph D. Smith, this city, general manager. The officers, with Mr. James Henry, Corning, N. Y., constitute the Board of Directors.

CASTILE.—The municipal electric light plant here, although a relatively small one, made an extremely good showing last year. The city authorities have voted an appropriation of $1,200 to cover a deficiency due to expenditures for plant construction last year which had not been covered in the previous appropriation, and have also issued bonds for $40,000 to cover a water system. Bids have already been advertised for the water plant and the construction will begin just as soon as the bids can be opened and the contract awarded. Mr. George W. Newman is superintendent of the plant.

SCHENECTADY.—A rather noteworthy achievement was accomplished here recently, when the entire electric current which lights the city and furnishes power for nearly all the manufactures was successfully transferred from the old substation in Dock Street to the new one. None of the lighting interests in the city were affected, and as the change was made about 1 A. M., when travel is light, the few trolley lines in operation at that time experienced but little inconvenience. The new station is now complete in every respect, and besides its lighting and industrial power service, it will furnish power for the operation of the new electric pump which is being installed at Rotterdam.

NORTH CAROLINA.

MAXTON.—Mr. John H. Cook is now president of the Carolina Electric Company.

KINSTON.—Contracts have been awarded for water works, a sewerage system and an electric light plant.

RALEIGH.—Reports state that the Raleigh Electric Company is preparing to construct street railway lines.

SOUTHERN PINES.—The electric light plant is owned and operated by Mr. R. L. Chandler under the style of R. L. Chandler Electric Light Plant.

KENTVILLE.—The Kentville Electric Light & Power Company is planning to install a small engine and dynamo to carry the load after 10 o'clock.

SALISBURY.—The plant of the Salisbury Gas & Electric Light Company was recently transferred by the company to the Salisbury Electric Railway Company.

SANFORD.—The Sanford Electric Light & Power Company is contemplating extending its service to Jonesboro, two miles distant, where 500 lights will be installed and supplied with current.

CONCORD.—It is expected that the municipal electric light plant will change over from direct to alternating current in the course of a few months. Sixty arc lights will be installed and 1500 incandescent lamps, as well as the necessary machinery to furnish the required current for the additional service.

LEXINGTON.—The electric light plant of the Lexington Water & Light Company, which was burned out, is to be replaced by a new plant for lighting purposes and water works will be added. The company has recently been operating two direct-current dynamos for lighting the church and a few stores.

NORTH DAKOTA.

CARRINGTON.—Mr. Karl H. Smith is chief engineer of the Carrington Electric Light Plant.

CASSELTON.—The electric light plant, which was formerly operated by the city, is now owned by Mr. B. A. Tenney.

DICKINSON.—Messrs. Hughes & Deiters, proprietors of the electric light plant, are contem-

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

plating installing a new tubular boiler some time during the coming summer.

OHIO.

NEWBURG HEIGHTS.—Bids are wanted for supplying the village with street lights.

CHICAGO JUNCTION.—The municipal electric plant is making general repairs to its lines.

MAYVILLE.—Mr. George E. Bamble is now superintendent and chief engineer of the electric light plant of Mayville.

DELAWARE.—Mr. E. E. Neff is now president of the Delaware Electric Light & Power Company.

BRADFORD.—A. W. McCune, G. S. Arnold and others recently incorporated the Bradford Electric Light Company with a capital of $10,000.

NAPOLEON.—Bids for $25,000 improvements to the water works and lighting plant have been called for.

NEWARK.—The Citizens' Electric Light & Power Company is contemplating the addition of one 600-kw. generator, a Corliss engine and two boilers to its plant equipment.

BELLAIRE.—The Belmont Electric Light & Power Company contemplates making additions and improvements to the power plant that will nearly double the capacity.

WILMINGTON.—The Wilmington Water & Light Company is erecting and equipping an entire new plant which will be ready for operation by September 1.

DICKINSON.—Messrs. Hughes & Deiters, who own the Dickinson electric light plant, expect to install a new tubular boiler some time during the summer.

BOWLING GREEN.—Messrs. J. H. La Farree and J. H. Ridley are now managers of the Lake Erie, Bowling Green & Napoleon Railway Company, which is successor to the Bowling Green Electric Light & Power Company.

SYCAMORE.—The following are the present officers of the Village Electric Light Plant: President, John Grafton; secretary, E. V. Ingerson; treasurer, G. A. Klahn; chief engineer, L. E. Patrick.

EATON.—The Eaton Light & Artificial Heat Company, which recently absorbed the stock of the local Electric Light, Power & Ice Manufacturing Company, is making preparation for the erection of a new electric plant.

LOWELLVILLE.—A new electric light plant is to be constructed at Newton Falls the coming summer. The contract for wiring the specifications has been let to Mr. H. B. Lee, electrician, of this city.

TOLEDO.—The council is advised by the Mayor in his annual message to empower the Board of Public Service to advertise for bids for installing a lighting system of 2000 arc lamps, to be paid for by the city in monthly payments without a bond issue.

NEWTON FALLS.—Press reports state that bids have been received by the city council for an electric light plant. The successful bidder will be given the contract for ten years for lighting the village and a twenty-year franchise for commercial lighting and furnishing power.

SHAWNEE.—Mr. C. P. Bauman, of Canal Winchester, Ohio, is now president of the Shawnee & Strainsville Electric Light Company; Mr. L. D. Bonebrake, of Columbus, is vice-president, and Mr. O. L. Bowers, Shawnee, treasurer and manager.

FREMONT.—The officers of the Fremont Yaryan Company, which owns and operates a heating and lighting plant here, are as follows: T. H. Jungk, president; E. S. Thomas, vice-president; J. W. Forsythe, secretary and treasurer, and W. B. Jessop, superintendent.

GALLIPOLIS.—The Gallipolis Electric Light Company has been consolidated with the Gallipolis Gas & Coke Company, and the business will be continued under the name of the latter company. Mr. C. F. Stockhoff is president; Mr. C. D. Kerr, secretary; Mr. C. W. Henking, treasurer; Mr. C. L. Steenberger, manager and superintendent.

CARDINGTON.—The electric light plant, formerly owned by G. M. Schambs, is now operated by the Cardington Electric Light, Heat & Power Company, of which Mr. W. P. Vaughan is president; Mr. W. E. Hull, vice-president; Mr. A. E. Curtis, secretary; Mr. J. W. Glauner, treasurer, and Mr. G. M. Schambs, manager.

DAYTON.—The report of the light committee and the city solicitor, declaring the legality of the contract between the city and the Dayton Light Company, has been adopted by the Board of Public Service. It was stated in our May issue that Mayor Snyder had vetoed the ordinance granting the franchise.

COLUMBUS.—While one of the five engines in the power house of the Columbus Railway & Light Company was undergoing repairs recently, another engine became disabled, necessitating shutting off the power until the latter could be repaired. This required a couple of hours, during which time traffic was interrupted.

FARGO.—The Fargo Gas & Electric Company has been consolidated with the Fargo Edison Company under the name of the Union Light, Heat & Power Company. The officers of the new company are as follows: President, William Mainland, Oshkosh, Wis.; vice-president, J. W. Smith, Fargo; treasurer, S. Mainland, Green Bay, Wis.; manager, O. G. F. Markus, Fargo.

MECHANICSBURG.—The Mechanicsburg Light & Power Company was recently organized with a capital of $9000. The company is composed of Messrs. T. J. and J. R. Long and Mr. E. J. Ward, and has secured the city lighting contract. At present it is furnishing only lighting current, but it is expected that a direct-current day circuit for power purposes will soon be in operation.

OKLAHOMA TERRITORY.

EL RENO.—The El Reno Electric Light & Telephone Company has been absorbed by the El Reno Lighting, Heat & Power Company. The officers of the new company are as follows: President, John A. Masters; vice-president, B. S. Trimble, of Jamestown, N. D.; secretary and treasurer, Frank Casey; chief engineer, H. T. French.

ENID.—The Chickasha Electric & Gas Company was recently incorporated with a capital of $450,000 by J. M. Dodson and H. H. Watkins, both of this city.

NORMAN.—It is reported that the Norman Milling & Grain Company will install another 125 horse-power high-pressure boiler at its plant this season.

OREGON.

ANTELOPE.—The question of constructing an electric light plant here is being considered by the citizens.

KLAMATH FALLS.—Mr. O. B. Bates is now superintendent of the Klamath Falls Light & Water Company.

STAYTON.—The Stayton Electric Light Company states that it is contemplating the addition of a 250-volt booster to its equipment.

ALBANY.—Mr. R. B. Martague has been appointed manager of the Albany Canal & Water Company, successor to the Albany Electric Light, Power & Telephone Company.

INDEPENDENCE.—It is the intention of the Independence & Monmouth Electric Light & Water Company to install a new dynamo and a step-up transformer at its power plant.

PORTLAND.—According to recent reports, it is the intention of the Portland General Electric Company to make extensions to its power plant involving an expenditure of about $250,000.

SALEM.—The following are the officers of the Salem Light & Traction Company: Mr. J. J. Henry, president and treasurer; Mr. H. C. Stoddard, superintendent, and Mr. Frank Johnson, chief engineer.

SUMPTER.—The Sumpter Light & Power Company is now officered as follows: President and manager, Robert E. Strahom, Spokane, Wash.; vice-president, R. J. Donson, Spokane; secretary and treasurer, A. G. Smith, Spokane; superintendent, J. W. Ball, this city. Mr. Ball states that work on the company's new plant will commence immediately.

ROSEBURG.—The Umpqua Water, Light & Power Company was organized March 1 by consolidating the Douglas Electric & Water Company and the Roseburg Water & Light Company. The capital of the company is $50,000, and the officers are: President, Mr. Fred J. Blakeley; secretary, Mr. Dexter Rice; treasurer and manager, Mr. T. S. Sheridan, and superintendent, Mr. F. H. Farrar.

BAKER CITY.—The Rock Creek Power & Transmission Company is installing a plant near this place. The equipment includes two 400-kw. three-phase 60-cycle G. E. generators, direct-connected to 900-h.p. water wheels with a speed of 450 r.p.m., and three 300-kw. transformers of the three-phase type. Current is to be transmitted to Baker City, a distance of 27 miles, and will also be furnished for power purposes to adjoining mining districts 17 miles in another direction. The plant is expected to be in commercial operation this month.

PENNSYLVANIA.

CARBONDALE.—The Hendrick Light & Power Company is incorporated with a capital of $5000.

NEW CASTLE.—A $75,000 bond issue is to be made by this city for the erection of a municipal electric light plant.

CORRY.—The Corry City Electric Light Company is contemplating the construction of a new power house.

SPANGLER.—Articles of incorporation have been filed by the Spangler Electric Light, Heat & Power Company with a capital of $5000.

JERMYN.—The Household Electric Light, Heat & Power Company is arranging to put in an extension of about 1½ miles of line shortly.

SHENANDOAH.—Local press reports state that bids are wanted by the Borough Council for furnishing 60 or more arc lights of 2000 candle-power.

BROOKVILLE.—The plant equipment of the Solar Electric Company will probably be increased shortly by the addition of a dynamo and a 150 horse-power engine.

MECHANICSBURG.—Mr. M. C. Kennedy is president of the United Electric Company; Mr. W. L. Ritchey is secretary and treasurer, and Mr. W. E. Guthrie is superintendent.

FRANKLIN.—The following are the officers of the Franklin Electric Company: President, Mr. W. J. Bleakly; secretary, Mr. H. A. Clawson; treasurer, Mr. O. D. Bleakly, and superintendent, Mr. B. F. Ott.

TARENTUM.—The city authorities are contemplating improvements to the municipal electric light plant, which, it is estimated, will cost from $10,000 to $12,000. They are also considering the adoption of the meter system.

EASTON.—The plant of the Lehigh Power Company, which has been idle since it was damaged by the floods last fall, has been purchased by Morris, Brother & Richardson, of Philadelphia, in consideration of $35,000.

DANVILLE.—It has been voted to establish a municipal light plant, and the Light Committee has been instructed to obtain estimates of the probable cost and maintenance of same prior to asking for bids.

CONSHOHOCKEN.—The Conshohocken Electric Light Company has secured a contract from the borough of West Conshohocken to light the streets of the borough at $15 an incandescent light. The contract stipulates that the borough shall exempt the company from pole tax and expect no reduction for the time lamps are out, unless the company is directly responsible.

MANHEIM.—The Manheim Electric Light, Heat & Power Company has been consolidated with the Lancaster Valley Electric Light Company, the officers of which are: President, Mr. A. W. Mentzer, Ephrata; manager and superintendent, Mr. F. E. Keiff, Manheim, and chief engineer, Mr. J. Weaver, Manheim.

WAYNESBORO.—The Waynesboro Electric Light & Power Company has increased its capital stock from $15,000 to $30,000. The officers of the company are as follows: Mr. W. Z. Minick, president; Mr. John M. Wolff, vice-president; Mr. E. C. Stull, secretary; Mr. M. E. Sallenberger, treasurer; Mr. J. F. Geiser, superintendent.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

DAWSON.—The Dawson Electric Light & Power Company is now owned and operated by the West Pennsylvania Railway & Lighting Company, of Pittsburg, of which Mr. W. S. Kuhn is president and manager; Mr. J. B. Van Wagener, vice-president, and Mr. H. F. Bomard, purchasing agent, all of Pittsburg; Mr. E. St. Clair Clayton, Dawson, is superintendent of the plant.

SOUTH CAROLINA.

ROCK HILL.—The Catawba Power Company is extending its lines to Charlotte and will supply current for power and lighting purposes.

BENNETTSVILLE.—The city authorities are considering the extension of the incandescent circuit of the municipal electric light plant to this place.

CLINTON.—The City Council is said to be considering a proposition made by some Washington capitalists to put in an electric light and water works system here. The proposition includes about forty hydrants and sixty lights, for which the parties ask $2000 and a forty year franchise, the town to have the privilege of purchasing the plant at the expiration of ten years or any five years thereafter.

GLEN CAMPBELL.—The Giant Electric Light, Heat & Power Company, which was organized the first of April, is furnishing electricity for lighting purposes to Burnside, Arcadia, Gipsey and Glen Campbell. The company is making arrangements to supply current for power purposes also. The officers are: Mr. S. J. Smith, president; Mr. Thomas Bellis, vice-president; Mr. A. M. Riddell, secretary; Mr. C. W. McCrady, treasurer, and Mr. D. H. Stroup, superintendent, all of this city.

SOUTH DAKOTA.

MADISON.—Mr. William Roche is now superintendent of the municipal electric light plant of Madison.

SALEM.—The officers of the Salem Milling, Lighting & Heating Company are: L. V. Schnider, president; W. S. Westfall, vice-president; H. C. Torry, secretary and manager; L. S. Tyler, treasurer.

IROQUOIS.—The equipment of the village electric light plant will probably be increased by the installation of a second dynamo, which will enable them to utilize all of the power furnished by the water wheel.

LEAD.—Mr. J. D. S. Rumsey, of Rochester, N. Y., is president of the Belt Light & Power Company; Mr. V. T. Price is vice-president; Mr. J. B. Baker, secretary and manager, and Mr. J. H. Fuller, chief engineer.

TENNESSEE.

JEFFERSON CITY.—The Jefferson City Electric Company states that in the near future its plant will be operated by steam.

BROWNVILLE.—The Burt-Smith Company is adding another dynamo to its plant equipment and extending its lines.

HUNTINGDON.—The electric light service has been very much improved by the installation of a new Corliss engine at the city electric light plant.

NASHVILLE.—The Southern Electric Company, with an authorized capital stock of $20,000, has been recently incorporated by Felix Shwab, W. K. Webb, F. O. Watts, W. O. Vertrees and W. M. Bowles.

CHATTANOOGA.—A bill authorizing the construction of a large power plant at the "suck" on the Tennessee River, has passed both Houses of Congress and is now a law. The bill as amended and passed grants the privilege of erecting the plant, first to the city of Chattanooga, and should the city not undertake the work or express its intention of so doing within four months, then the privilege is granted to Messrs. C. E. James and J. C. Guild and associates, who will be allowed eight months in which to declare their intention of accepting it. The cost of the dam and locks, together with the land bordering on the river at that point to be used in connection with the power plant, is estimated to be about $2,000,000. This is all to be provided for by the parties erecting the plant, and upon the completion of the work the dam and locks are to be deeded to the Government, in consideration of which the Government guarantees the privilege of using the water power thus secured for the purpose of operating an electrical power plant.

TEXAS.

HOUSTON.—Mr. Clarence George has been appointed city electrician.

SULPHUR SPRINGS.—B. Ashcroft & Sons now own and operate the electric light plant of this place. Mr. C. P. Smith is superintendent.

McKINNEY.—The McKinney Electric Light & Motor Company is now being managed by Mr. L. A. Scott, who is also president of the company.

CALDWELL.—Cypher Brothers, of Austin, are contemplating the construction of an electric light and ice plant here at a cost of about $10,000.

LADONIA.—The City Electric Light & Water Works Company is increasing the voltage of its circuits to 104 and putting in new transformers.

TERRELL.—The Terrell Electric Light Company is reported to be increasing the amount of copper on its lines.

CARTHAGE.—Mr. John Whitney, proprietor of the electric light plant, is planning to give the plant a general overhauling and may possibly install a more economical prime mover.

MACOGDOCHES.—Mr. E. E. Branch is president of the Macogdoches Light & Power Company; Mr. K. P. Branch is vice-president, and Mr. O. E. Hubbard is secretary and manager.

LEONARD.—The Leonard Electric Light & Ice Company was recently organized for the purpose of erecting an electric light and ice plant. Mr. Y. T. Manning is president, and Mr. L. H. Saunders, secretary of the company.

THURBER.—Mr. Thomas R. Termont is now superintendent of the Texas Pacific Mercantile & Manufacturing Company, which furnishes alternating current for three arc lamps and 1500 incandescent lights.

CLARENDON.—Two franchises for the operation of electric light plants here have been granted by the city council. One was to Chase & Company, who have been operating a plant in this city for some time, while the other was granted to James Trent, who will immediately install a plant.

DECATUR.—The Decatur Electric Light Company is now known as the Moore Milling Company, with a capital stock of $20,000 fully paid up. The officers, all of Decatur, are: President, Mr. J. J. Perkins; vice-president, Mr. C. M. Moore; chief engineer, Mr. J. W. Moore.

AMARILLO.—The Amarillo Light & Water Company has been succeeded by the Amarillo Water, Light & Power Company, of which Mr. L. W. Chase, of Cleburne, is president; Mr. W. F. Ramsey, Cleburne, vice-president; Mr. A. L. Chase, of Amarillo, secretary and manager, and Mr. John K. Bryden, of Pittsburg, Pa., treasurer.

AUSTIN.—It was stated recently that an offer might be made to rebuild the Austin dam on the basis of revenues from the water and light plant for a number of years. Mr. R. H. Ingersoll, who is interested in water power plants in other states, has been here looking over the situation, and it is thought he may submit a proposition before long.

HOUSTON.—The addition to the plant of the Houston Light & Power Company has been completed and the machinery is being installed. The equipment includes three 450-h-p. Babcock & Wilcox boilers, a turbine engine and dynamos. Wires are being extended to nearly all parts of the city and the plant will be ready for operation by September 1.

PORT ARTHUR.—The Port Arthur Light & Power Company has been consolidated with the Port Arthur Water Company under the name of the latter. The joint company is operating on a capital stock of $200,000, and the following are its officers: President, Mr. George M. Craig; vice-president, Mr. H. Y. Arnold; secretary, Mr. R. H. Woodworth; treasurer, Mr. Frank Woodworth; manager and superintendent, Mr. George A. Taylor.

UTAH.

FOUNTAIN GREEN.—The Big Springs Electric Company may extend its lines twelve miles further in order to furnish current for lighting purposes to Ephraim.

SALT LAKE CITY.—The Utah Light & Railway Company has arranged for an additional 1000 horse-power of current with the Bear River power plant, in anticipation of the demands of the next fall and winter. It is expected that another 1000 horse-power will be required in the course of another year.

VERMONT.

ESSEX JUNCTION.—Mr. S. A. Brownell is now president and manager of the People's Electric Light & Power Company's plant of this place.

BARRE.—The People's Lighting, Heating & Power Company, an organization composed of citizens of this city and Burlington, is arranging to construct a large gas plant soon.

MANCHESTER. The Manchester Light & Power Company is understood to be negotiating for the purchase of the Vail Light & Lumber Company's plant.

RUTLAND.—The Rutland City Electric Company recently installed a new $4000 switchboard at its electric light station. The board contains eleven panels and is equipped with the latest appliances.

BURLINGTON.—The Street Committee is arranging for the plans and specifications of the municipal lighting plant for which the city is bonded for $58,000. It is estimated that a plant capable of developing 250 kilowatts will meet the present requirements. Of this, 125 kilowatts will be used for lighting the public highways and 25 kilowatts for the lighting of buildings. The plant will be housed in a brick building to cost $5,000, and space will be allowed for the installation of two extra units when they become necessary.

VIRGINIA.

WEST POINT.—Recent reports state that an electric light plant is soon to be installed here.

FREDERICKSBURG.—Mrs. E. C. L. Ficklen is now owner of the Rappahannock Electric Light & Power Plant; Mr. E. M. Greene is superintendent.

CULPEPER.—The Culpeper Electric Light Company expects to erect a 6-ton ice plant which will be operated by power supplied from its present plant.

BIG STONE GAP.—The electric light plant is now owned by the Wise Electric Company, of which Mr. C. C. Cochran is president and manager, and Mr. S. R. Cochran is secretary and treasurer.

MARTINSVILLE.—The council is considering the installation of an electric light and power plant capable of developing 1000 horse-power, to furnish current for lighting the town and supply power for industrial purposes. The plant will be operated by water power obtained from Smith River, about a mile south of the town, and will probably cost $70,000.

WASHINGTON.

ABERDEEN.—Mr. E. A. Bradner has been made superintendent of the Gray's Harbor Electric Company.

MONROE.—The Monroe Water & Light Company has been organized to construct and operate water works and an electric light plant.

PALOUSE.—The Palouse Electric Company is asking the City Council for a 25-year franchise. The matter has been referred to the committee.

WHATCOM.—The local lighting company has been awarded a three-year lighting contract by the City Council.

OLYMPIA.—The Olympia Light & Power Company has been granted a franchise for the extension of its car lines.

ABERDEEN.—It is understood that local capitalists are considering making an application to the City Council for an electric light franchise.

PORT ANGELES.—Messrs. G. G. Teachman and David Ferguson are manager and chief engineer respectively of the City Electric Light Company.

BELLINGHAM.—The city council is considering the purchase of the lighting plant now operated by the Bellingham Bay Improvement Company.

SEATTLE.—The construction of an interurban line between Seattle and Everett, a distance of

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

about 38 miles, will be begun about the first of July.

SEATTLE.—The municipal electric light plant, located on Cedar River, which is expected to be ready for operation in August, is nearly completed and work on the construction of the pole line from the power house to this city is already under way.

NORTHPORT.—The Northport Electric Light Company's plant was destroyed by fire on the morning of May 4. The loss on switchboard, machinery, supplies and building will approximate $4000. Mr. Robert Morrill is owner and manager of the plant.

VANCOUVER.—It has been decided to install an electric light plant at the post here and it is probable that the Vancouver Electric Light Company will receive the contract for a term of years. The company is said to be making arrangements to install a 500-h.p. engine to supply the necessary power.

WEST SEATTLE.—The city has voted bonds for $18,000 to build and equip an electric street car line, power for which will be furnished by one of the several large Seattle companies. One line will be built, connecting at the Sound with the ferry boats and running through the town to the western city limits.

SEATTLE.—The City Council is considering the advisability of operating electric sprinkling cars in the congested down-town districts. The Seattle Electric Company, it is understood, has offered to run the cars at cost, an ordinance for the purchase of which will be introduced at the next meeting.

WATERVILLE.—The contract for the complete installation of the Waterville transmission plant, to be erected on the Enteat River, has been awarded to Mr. George Nixon, of Spokane. The available water power is 3000 horse-power and the present development is for 250 horse-power. Three-phase current at 6600 volts will be transmitted from the power house to the town, a distance of nine miles.

SPOKANE.—The Washington Water Power Company recently secured the contract for 500 horse-power of electricity to operate all of the machinery of the Morning mine, three and a half miles above Wallace, Idaho, on the Cœur d'Alene River at the mouth of Grouse Gulch. Preparations are being made to extend the line the necessary four miles, and a sub-station will be built at Grouse Gulch, which will be in operation by September 1, when the contract goes into effect. The contract is for a minimum of 300 horse-power for five years. The company also has contracts for a minimum of 1800 horse-power a year among other mines of the Cœur d'Alenes, and from Spokane Falls is operating machinery in the Standard, the Hecla, Mammoth, Bunker Hill and Sullivan, and the Last Chance, besides several smaller mines.

SEATTLE.—The Snoqualmie Falls & White River Power Company is a consolidation of the Tacoma Cataract Company, the Snoqualmie Falls Power Company and the Seattle Cataract Company, with a capital stock of $3,000,000 all paid in. The company's officers are: Mr. Charles H. Barker, president and manager; Mr. O. D. Colvin, first vice-president; Mr. E. C. Newfelder, second vice-president; Mr. Thomas B. Hardin, secretary; Mr. Lester Turner, treasurer; Mr. John Harrisberger, superintendent. The company furnishes electricity for lighting purposes to Tacoma, Issaquah, Renton and Auburn, besides Seattle.

SEATTLE.—The Board of Public Works has granted the Citizens' Light & Power Company the privilege of extending its lines throughout what is known as the Belmont Avenue district. The cost of this improvement is estimated at about $50,000. It is said that the company is planning to make other extensive additions to its plant. Other local light and power companies are contemplating the expenditure of large sums of money in improvements during the coming season, and it is expected that within a short time the Seattle Lighting Company will install its mains in the Renton Hill, Beacon Hill and other residence localities.

CHELAN.—Mr. W. J. Long. of the Chelan Water Power Company, is said to be interested in the promotion of a new electric railway enterprise to be known as the Big Bend Railway Company. Mr. A. Bettes, of Spokane, Wash., and Mr. J. E. Sullivan, of Coeur d'Alene, Idaho, who are the promoters and builders of the line from Coeur d'Alene Lake, are also interested in the new undertaking. The line will run from Rock Island on the Great Northern Railroad through the immense wheat fields of the Big Bend country to Chelan, on the Columbia River. Twenty miles is to be constructed this year, and the complete line is to be in operation a year from next fall.

WEST VIRGINIA.

WHEELING.—The Belmont Electric Light & Power Company has in contemplation important additions and improvements which will nearly double the capacity of its plant.

RICHWOOD.—The Richwood Light & Power Company states that it is in the market for 2500 16-c.p. incandescent lamps and 14 arc lights, with the necessary electric generating machinery for operating the same.

MORGANTOWN.—It is reported that on May 1 the Union Utility Company reduced its rates for lights from 12 to 10 cents per 1000 watts. A discount of 5 per cent will be allowed on all bills over $3 per month, and the minimum charge of 75 cents per month to each customer will be continued.

WISCONSIN.

LAKE GENEVA.—The Equitable Electric Light Company is constructing a mile of new line.

WITTENBERG.—Bids are wanted for the construction of an electric light plant.

ELKHORN.—Mr. Paul Prisk has been appointed superintendent of the city electric light plant.

TOMAH.—Mr. A. H. Nelson is now manager and chief engineer of the local electric light plant.

GLIDDEN.—Reports from this city state that there is a good opening for an electric light plant there.

PORTAGE.—Mr. R. E. York is secretary and treasurer of the Portage Electric Light & Power Company.

MENOMONEE FALLS.—The city council is said to be interested in the construction of an electric light plant at this place.

LAMARTINE.—The Lamartine Heat, Light & Power Company is contemplating the erection of a new stone building, 30 x 400 feet.

IRON RIVER.—The Iron River Water, Light & Power Company will change shortly from steam to water power for operating its plant.

ELKHART LAKE.—The Sheboygan-Elkhart Lake Railway & Electric Company is arranging to furnish lighting current to a neighboring town.

BURLINGTON.—A meeting is soon to be held for the purpose of voting on the issue of $27,000 bonds for the construction of an electric light plant.

EAU CLAIRE.—The electric light committee, of which Mr. Emmet Horan is chairman, is considering the question of installing a municipal electric light plant.

GREEN BAY.—The Green Bay Light & Power Company has started work on the extensions to its buildings and plant, which have been contemplated for some time.

WAUKESHA.—Mr. F. A. Dombrook, chief engineer of the Milwaukee Electric Railway & Light Company, recently delivered a lecture on "Electric Power and Transmission" before the local order of stationary engineers.

CANADA.

BERLIN, ONT.—The plant and property of the Berlin Gas Company have been acquired by the town of Berlin.

NIAGARA FALLS, ONT.—The Niagara Falls electric light plant is now owned and operated by the city council.

NELSON CITY, B. C.—Bonds have been issued for the erection and equipment of a 3000-h.p. plant for power and lighting purposes.

EXETER, ONT.—The Exeter Electric Light Plant, which is owned by C. B. Snell, is arranging to install more town lights.

THREE RIVERS, QUE.—The North Shore Power Company is now supplying lighting current to Cape Madelaine and St. Narcisse.

SHELBURNE, ONT.—The electric light plant is now owned by Mr. James Pickering. Mr. Pickering has the city lighting contract and also furnishes current to Millbrook for lighting purposes.

PRINCE ALBERT, N. W. T.—The town of Prince Albert is making extensions to its plant and equipment. These include an engine, boiler and dynamo.

PAKENHAM, ONT.—The Pakenham electric light plant is now owned and operated by the Down Milling Company, Ltd., of which Mr. H. S. Dowd is president.

SELKIRK, MAN.—The plant of the Selkirk Electric Company, Ltd., is now owned by Mr. Robert Oakland. The plant generates current for both lighting and power purposes.

RENFREW, ONT.—A. A. Wright & Co. have been succeeded by the Renfrew Electric Company, of which Mr. A. A. Wright is president and manager; Mr. W. A. Wright is secretary, and Mr. G. Fyfe is superintendent.

AURORA, ONT.—Mr. W. H. Birchard is now proprietor of the plant formerly owned by the Aurora Electric Light Company. The equipment consists of a condensing engine and an alternating current dynamo. Mr. Birchard has the contract for the city lighting.

OTTAWA, ONT.—Reports state that the question of putting the overhead wires underground has been settled, and the Consumers' Electric Company is preparing to expend about $30,000 in laying conduits for this purpose from the Chaudiere to its power station on Maria Street.

SHAWINIGAN FALLS.—The Shawinigan Falls Water & Power Company recently let the contract for the construction and installation of a new transmission line for transmitting electrical power generated by the company at its power house at the Falls to Montreal, a distance of 85 miles.

ST. CATHARINES, ONT.—The Lincoln Electric Light & Power Company is installing in its plant a new 300-kw. three-phase generator for power and lighting purposes, and is building a three-phase line to the power house of the Hamilton Cataract Power, Light & Traction Company for the lighting of the new Welland Canal.

MEXICO.

COLIMA.—The contract is said to have been let for the construction of the electric lighting system in this city.

PUEBLA.—Sr. Ernesto Gutierrez, of Mexico City, is now manager of the Compania Anonima del Alumbrado Electrico Estacion de Nopolito.

JALAPA, VERA CRUZ.—The Jalapa Railroad & Power Company has extended its lines to Xico Ciateper and Teicelo and is now supplying lighting current to those towns.

LAS JUNTAS.—The Campania Maustral de Guadalajara, which at present is operating a 2000-h.p. hydraulic plant at this place for the purpose of transmitting current to Guadalajara, chiefly for lighting purposes, is preparing to increase the capacity of its plant by the addition of new equipment capable of developing 2000 horse-power.

SILAO.—Mr. George B. Hyde, an American, now a resident of this place, has made application for permission to erect three electric power plants in the State of Peubla to furnish power for operating machinery in the mines located in the Tetela de Ocampo district. The Zempoala River will furnish the water power for the plant.

MEXICO CITY.—The large water power and electric transmission plant, which is being constructed by the Mexican Light & Power Company in the State of Puebla, 90 miles from this city, will have an initial capacity of 45,000 horse-power. In order to secure a suitable site for the necessary reservoir, it was found necessary to move a town of 1000 inhabitants. The company purchased the entire town and all the buildings were razed and reconstructed on the new site.

HOSTOTITAQUILLO, JALISCO.—Francisco Brenna, of Mexico City, has secured the necessary concession from the State Government for the erection of a hydraulic plant on the Rio Grande de Santiago, for the purpose of supplying towns in the vicinity with current for lighting purposes. The franchise permits the utilization of 15,000 liters of water per second.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

American Electrician.

Vol. XVI. New York, July, 1904. No. 7.

A LARGE PARISIAN ELECTRIC GENERATING PLANT.

THE MOULINEAUX POWER STATION IN PARIS.

BY FRANCIS PAUL.

Among the large stations which have been erected in Paris within the last few years, the Moulineaux plant, which lies in the suburbs of the city, is one of the largest and best equipped. This station is controlled by the Compagnie des Chemins de Fer de l'Ouest and was built and is operated by the Compagnie Generale de Traction conjointly with the Societe Industrielle d'Electricite, which represents the Westinghouse interests in France. The latter company installed all the electrical apparatus, while the engine and boilers were supplied by French companies. The Moulineaux plant supplies current for lighting circuits and for operating the new electric railroad which runs from the Invalides Station in Paris to Versailles, as well as different traction lines in the city. The station also delivers current to a part of the Metropolitan circuits.

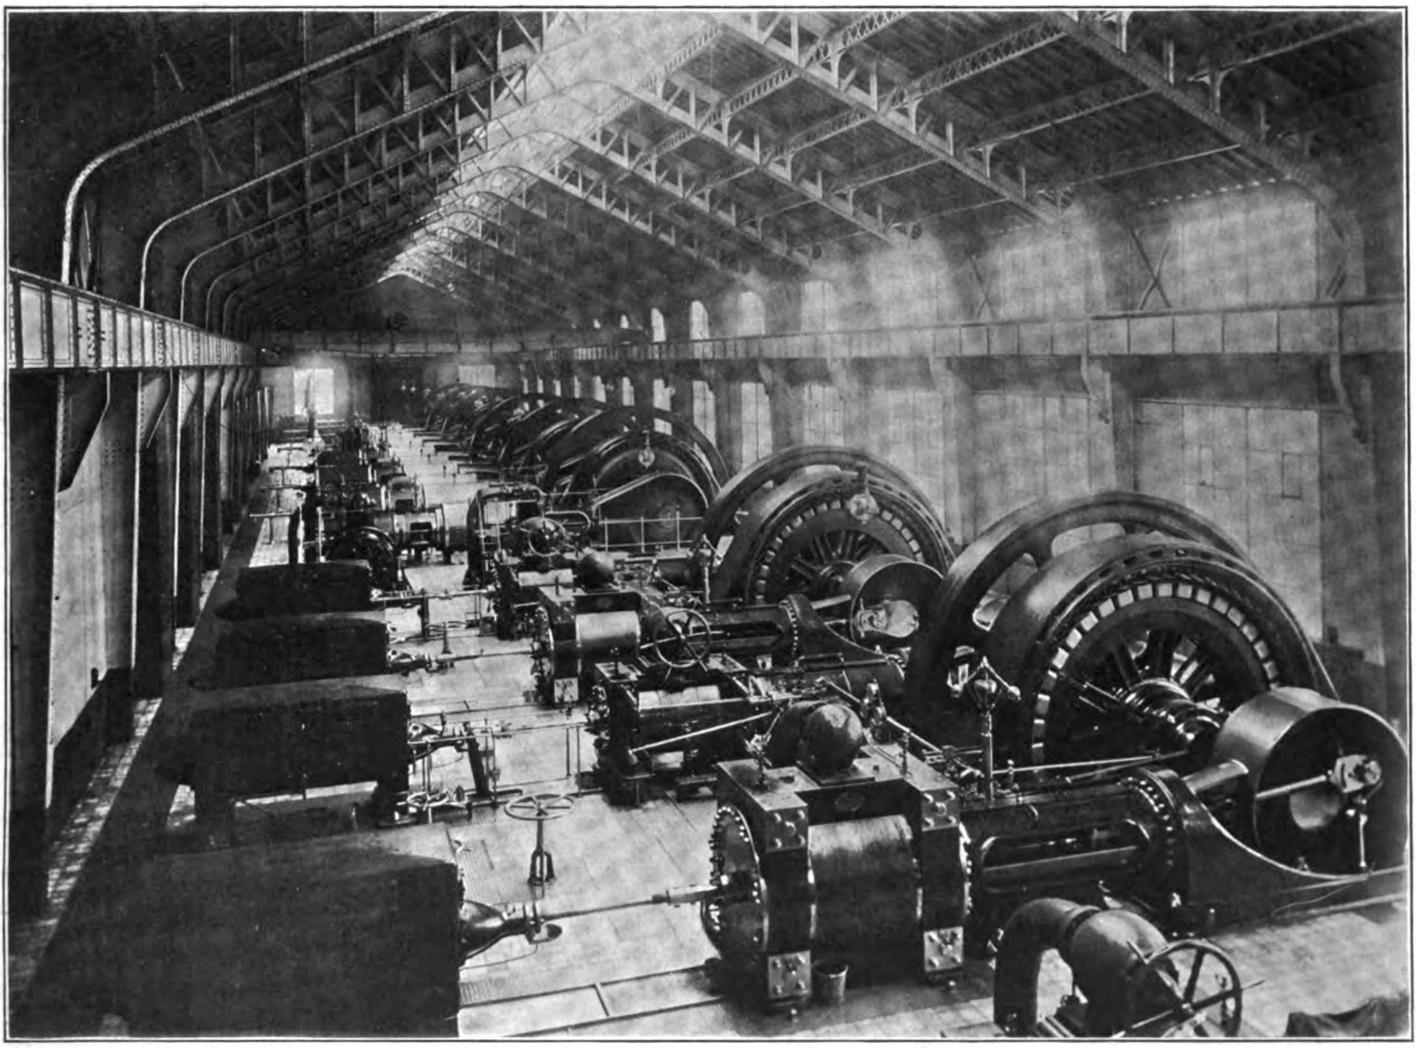

FIG. 1.—GENERAL VIEW OF ENGINE ROOM, MOULINEAUX POWER STATION.

The plant occupies a large plot of ground lying on the banks of the Seine just outside the city. It has good railroad facilities, so that coal can be easily supplied, and the cars are run in directly from the railroad. Coal can also be taken from barges on the Seine. The principal part of the Moulineaux plant is the main building which contains the dynamo and boiler rooms. It measures 370 feet long and 130 feet wide. The side next the river contains the machinery, while the sea part contains the boilers and coal supply. The station develops a normal output of 7500 kilowatts, but has a considerable reserve power which will come into use with the further development of electric traction.

The boiler house contains nine batteries of three boilers each and has especially good facilities for handling coal as well as for disposing of the ashes and cinders. The nine batteries of boilers are arranged in a single row, which extends the whole length of the building, as Fig. 2 shows. To the right will be observed the disposition of the coal supply. The coal is fed into a row of bunkers which lie parallel to the grate fronts. Some repairs were being made here at the time of taking the photograph, which accounts for the apparent disorder. The boilers were built by the Meunier Company, of Lille. They are of the type known as "semi-tubular," which is used considerably in France. This type of boiler is preferred where the load is extremely variable.

The coal is usually brought to the station on railroad cars, and a track has been laid alongside the boiler room so that the coal can be dumped directly from the cars into the bunkers. When coal is delivered from barges on the Seine, it is unloaded on the wharf and a small industrial railway brings it to the bunkers. The cinders are handled very conveniently by means of small cars which travel along under the boilers on a track laid in a tunnel. The cinders fall from the grate into a pit which has a gate opening into the side of the tunnel, so that the cinders can be dumped directly into the cars. The latter are then run out to the forward end of the tunnel, where the cars dump into a pit; a motor-driven conveyor takes the cinders from the pit and elevates them over the railroad cars, into which they are finally delivered.

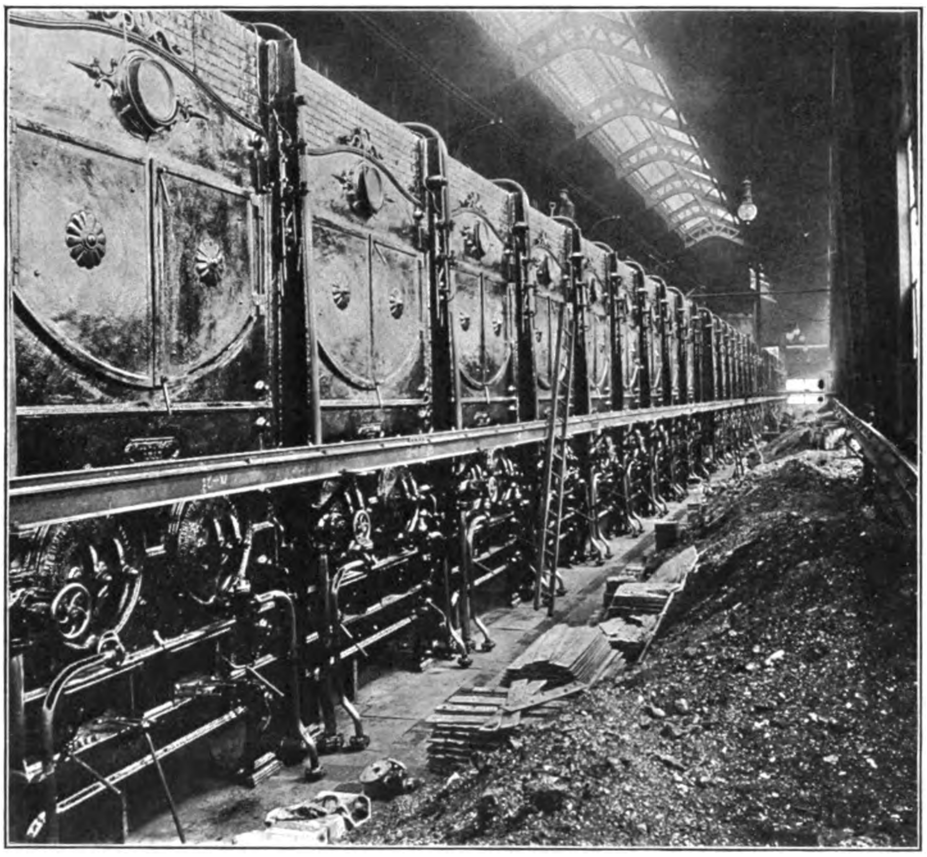

FIG. 2.—BOILER ROOM OF MOULINEAUX POWER STATION.

The boilers use the water coming from the condensers. It is taken at the outlet of the condensers by pumps which are operated from the main engine. Two small Worthington pumps in the boiler room are used as a reserve, and these take water directly from the main reservoir of the station. The excess of condenser water is sent into the overflow main by a discharge valve. The cooling water for the condensers is taken from the Seine by six centrifugal pumps, which are direct-driven by electric motors of 50 horse-power and are located in a separate building. The water is elevated from the river to the main reservoir, which has a capacity of about 80,000 U. S. gallons. A system of piping, partly of beton conduit and partly of iron pipe, carries the water from the reservoirs to the condensers. A second conduit lying below the former returns the condenser water to the Seine.

The products of combustion of the furnaces pass into an underground tunnel which is connected to three chimneys, one located near the middle of the boiler room, and the others outside at either end of the building. The chimneys are 160 feet high and 10 feet in diameter at the base.

The main steam piping passes along above the boilers, and each of the latter is connected to it by a valve. From the main pipe a branch pipe leads to each engine, passing behind the boilers and then descending into the basement under the main dynamo room, which contains all the piping for the engines.

The spacious room which contains the generating units is one of the largest dynamo rooms in France. The front page engraving shows a general view of this part of the station, in which the arrangement of the generating units, which are similar in character, will be observed. This room is 370 feet long and 65 feet wide, and is well lighted on the side next the Seine by a series of large windows. It contains the main alternators, the exciter groups, and a switchboard of eighteen panels. The latter is mounted in a gallery at one end of the station. There are nine alternating-current three-phase generators direct-coupled to horizontal steam engines, arranged in a single row along the length of the building. Spaces are left between the third and fourth machines and between the sixth and seventh in which are located the exciter groups with upright engines, of which there are four in all.

The alternators are of the Westinghouse type and of uniform construction. Each unit is designed to give 800 kilowatts on average running, or 1100 kilowatts maximum. Six of the alternators are driven by engines which have been furnished by the Dujardin Company, of Lille. The engines of the three remaining groups have been supplied by Garnier and Faure Beaulieu, of Paris. The four exciter groups are direct-coupled to Westinghouse engines of the well-known upright pattern. The main dynamo hall is equipped with two large electric traveling cranes of 20 tons each.

Under the dynamo room is a basement which runs for the whole length and contains the steam and water piping for the engines, as well as a part of the condensers and pumps. As the basement lies below the high-water level of the Seine, it had to be specially constructed so as to make it water tight. The whole surface of the floor is constructed of armored beton about three feet thick, upon which rest the foundations of the engines and dynamos.

Besides the main building, devoted to the machines and the boilers, the plant contains various buildings, for the different purposes of the station, including repair shops, storerooms, pump house and reservoir, offices and testing room.

The Dujardin engines which form part of the first six groups (in the background of the figure) are of the triple-expansion type with four cylinders. They have two cylinders in tandem on each side of the alternator. These engines operate at 80 revolutions per minute. The diameter of the high-pressure cylinder is 26 inches; the intermediate and low-pressure cylinders measure 44 inches; the stroke is 54 inches. The governor acts upon the high-pressure valve-gear, but for the other cylinders the steam admission is constant. These engines are of the condensing type and the condensers (of which there are two for each engine) are located in the basement directly below the cylinders. If need be, the engines can be made non-condensing by means of a valve in the exhaust piping, in the usual way. The engines drive the air-pumps of each condenser and also the feed-pumps which are connected with the main water conduit. While the normal power of the Dujardin engines is 1350 indicated horse-power, they can be run as high as 1700 horse-power, as has been shown in the tests. The cut-off is fixed in the case of the intermediate and low-pressure cylinders, and these work at 35 and 50 per cent respectively. For the high-pressure cylinder, the cut-off is variable and is controlled by the governor so as to work between the limits of 26 per cent for a load of 800 kilowatts and 40 per cent for 1100 kilowatts, which is as high as they are expected to run.

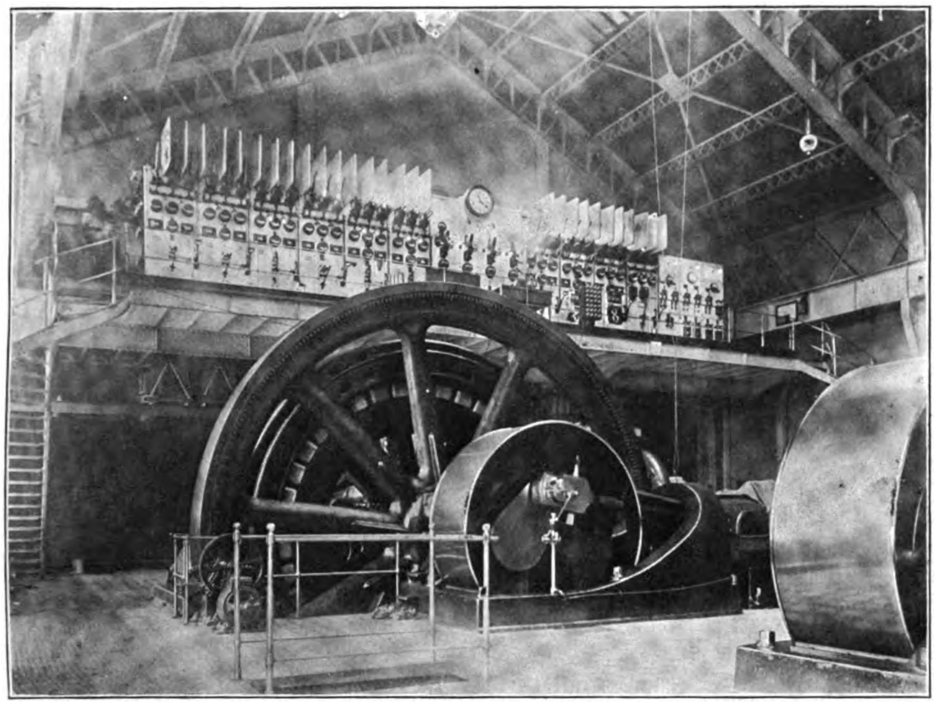

FIG. 3.—VIEW SHOWING SWITCHBOARD GALLERY.

As the inertia of the alternator is insufficient for the proper running of the engine at varying loads, a heavy fly-wheel has been added to each unit. It is placed on the side of the intermediate cylinder, while the alternator is mounted between the fly-wheel and the high-pressure cylinder. The fly-wheel measures 24 feet in diameter and weighs 22 tons. The cylinders of the engines are provided with steam jackets. Steam at boiler pressure passes through the high-pressure cylinder jacket before it enters the cylinder. For the other cylinders, the steam pressure is lowered to 75 pounds. The Dujardin engines are provided with automatic oiling apparatus. After passing through the engine the oil is collected in a reservoir and then goes through a filter. The oil is made to circulate by means of small pumps which are operated from the engines.

The Garnier and Faure Beaulier engines which are used with the last three alternators (noticed in the foreground) are of the Corliss cross-compound type, with cranks placed at 90 degrees. The normal steam pressure at the throttle is 130 pounds per square inch. The high-pressure cylinder is 30 inches in diameter and the low-pressure 55 inches, with a common stroke of 52 inches. The engines operate at 80 revolutions per minute. The admission of steam is variable in both cylinders, the governor controlling both valve-gears at the same time. The cut-off for the normal load of 800 kilowatts is 20 per cent for the high-pressure cylinder and 35 for the low-pressure. In the case of the high-pressure cylinder the admission valves are situated at the upper part, while the exhaust valves are placed below. Like the preceding engines, arrangements are made for allowing them to exhaust at atmospheric pressure, but ordinarily condensers are used. The latter are placed on the main floor and are located back of the cylinders, as will be observed. The air-pump of the condenser is operated by a prolongation of the piston-rod. The feed-pumps and other apparatus for the condensers are located underneath the engines in the basement. The cylinders are steam-jacketed. A heavy fly-wheel, 23 feet in diameter and weighing 25 tons, is mounted on the alternator shaft. Each of the groups in the dynamo room is provided with a small three-phase motor for "turning over." The motor operates a pinion which engages with the teeth which the fly-wheel carries on the periphery.

The four upright exciter units are set in pairs in the two spaces left between the alternator sets. Fig. 4 shows two of the groups. The generators are driven by high-speed Westinghouse compound engines and are mounted on the same bed-plate. The engines take a steam pressure of 130 pounds at the inlet. The high-pressure cylinders have a diameter of 13 inches and the low-pressure, 22 inches; the stroke is 13 inches and the speed 290 revolutions per minute. Each engine has an individual condenser. The exciters, which are of the standard Westinghouse pattern, are 120-volt machines, with eight poles of laminated iron. The main exciter circuits pass under the floor to the switchboard. The current is used for exciting the fields of the alternators, of course, and also for lighting the different buildings of the station. Part of the current is also used by the motors which drive the different pumps situated on the premises, as well as for a number of motors in the repair shops and testing room.

The nine alternators of the Moulineaux station are of identical construction. These machines have been erected by the Westinghouse Electric Company and the present plant was one of the first large stations to be equipped by that company in France. The alternators are designed to give three-phase currents at 5000 volts and a frequency

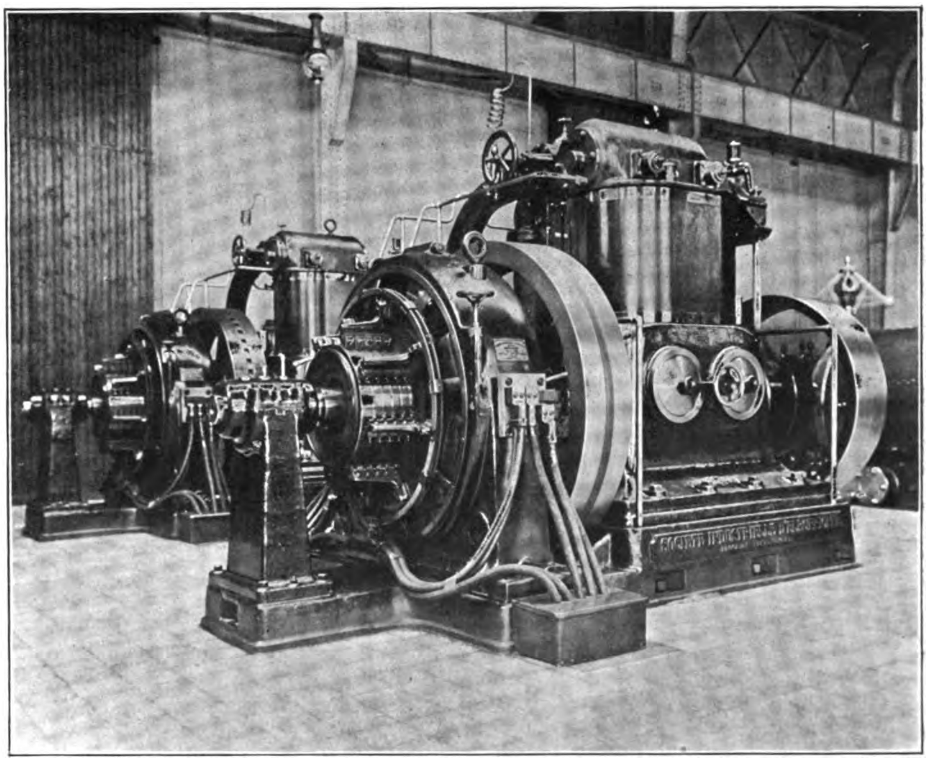

FIG. 4.—STEAM-DRIVEN EXCITER UNITS.

of 25 cycles. The revolving field-magnet is of the usual laminated construction, mounted on a central fly-wheel. It has a series of openings for cooling, which correspond with a similar set of holes in the outer armature ring of the machine. The diameter of the revolving part of the alternators is 14 ft. 2 ins. The central fly-wheel is formed of two parts which are bolted together.

The field winding consists of flat copper strips and each pole contains 49 turns. All the field coils are connected in series and the exciting current is brought by copper brushes from a pair of collector rings. The fields of these alternators are excited at 110 volts. The current which is required varies from 175 amperes at no load to 195 at full load.

The armature is wound for 5000 volts, no step-up transformers being used; it is connected star fashion. The core contains three slots per pole per phase, or nine per pole. The slots, which measure 14 x 40 millimeters, contain four well-insulated conductors each. The total length of armature iron measured along the axis is 572 millimeters, which includes the ventilating spaces. The internal diameter is 4.674 meters across the laminated part. The weight of the external housing is about 40 tons. It is arranged so as to slide back and forth for inspection or repairs.

As to the consumption of coal in the station, it may be remarked that the tests which were made at the beginning showed a consumption at full load equal to 2.2 pounds of coal per kilowatt-hour measured at the mains leaving the station. This figure includes all the different auxiliary apparatus needed for operating a group, such as exciters, pumps, etc. The consumption proved about the same for both types of engines.

One of the engravings shows the large switchboard which has been installed at one end of the station. The main part of the switchboard is located on an elevated platform which is reached by an iron staircase at either end. The switchboard is built of white marble panels mounted on an iron frame. There are generator panels (one for each machine), four exciter panels and five panels for the feeders. An automatic circuit-breaker of long stroke is used for each machine; it has the usual copper and carbon break, and is shielded by a projecting panel on each side.

Each of the alternator panels contains three ammeters (one for each phase) and two wattmeters which give the total power of the machine by adding their readings. The alternator panel is completed by the usual apparatus for controlling the field current, including a rheostat, ammeter and switch. The latter is arranged so that it cannot be operated except when the alternator circuit is properly connected. To synchronize the alternators for coupling in parallel, a phase lamp is used which is enclosed in a dark box. Synchronism is shown by the extinction of the lamp. The switchboard is provided with a main voltmeter and "total output" ammeter. The voltmeter is connected by a commutator with the secondaries of the synchronizing transformers. The exciter panels are of the usual character. A common voltmeter is used with all four machines and is connected in by a plug and flexible cable. Each exciter panel carries an automatic circuit-breaker, switch, ammeter and rheostat. The feeder panels carry each a circuit-breaker, three ammeters and a wattmeter.

The current is brought from the machines to the main switchboard by a set of cables which pass in conduits under the floor of the station and then rise to the gallery back of the switchboard. From the main switchboard, the high-tension current is carried to a second switchboard placed below the former and on a level with the first floor. It serves as the starting point for the feeders which leave the station and contains the necessary meters for taking the readings of each distribution circuit. The high-tension feeders leave the station underground. The cables which supply the Invalides-Versailles electric road are of the Berthoud-Bonel three-conductor type and are laid along the tracks as far as the terminal of the Champ de Mars. The electric road is supplied at 500 volts by several sub-stations.

The Moulineaux station has been running very successfully ever since the outset, and the demand for current is constantly increasing. It is under the supervision of the director, M. Tainturier, a well-known engineer of Paris.

◆

NOTES ON INTERHEATING RECEIVERS FOR COMPOUND ENGINES.

The efficiency of interheating receivers for compound engines as a means of reducing the net steam consumption has often been discussed by engineering writers but without any general agreement as to whether or not the saving in fuel obtained by their use was worth the added cost and complication. The majority of engine builders seem to have concluded that, as it is a case where the doctors disagree, the sharpness of competition renders it inadvisable to include interheating receivers in their specifications unless called for by the purchaser. On the other hand, such a large proportion of the best economy records for both steam engines and steam pumping machinery has been obtained with interheating receivers that the cases where indifferent results have been secured are apparently due to the lack of a clear understanding on the part of some of the makers of such apparatus of just what an interheating receiver should be expected to accomplish.

The sole object of an interheating receiver should be to superheat efficiently the steam entering the low-pressure cylinder, by a transfer of heat from steam at boiler pressure (which by reason of its higher temperature is suitable for this purpose), to the steam exhausted from the high-pressure cylinder. The gain in economy is precisely of the same nature as that obtained by supplying superheated steam to the high-pressure cylinder. It is generally conceded that the saving from a moderate degree of superheat, such as will prevent internal cylinder condensation, say up to a superheat of 100° F., is much greater proportionately than the added gain from carrying the degree of superheat materially higher, not to mention certain decided disadvantages which accompany a high degree of superheat. It follows, therefore, that the interheating receiver will give the considerable advantages of a moderate superheat for the low-pressure cylinder in any station, and in power stations where a superheated steam supply is available, the full saving to be commercially gained from the use of superheated steam can be effected without the necessity of a high degree of superheat in the steam supplied to the high-pressure cylinder. A properly constructed interheating receiver involves no additional complication or attendance other than means for returning to the boiler the condensation in the heater coils. This can be accomplished by the high-pressure drip return system, which should be provided in every well-designed station to return the water of condensation from the high-pressure piping and separators.

Since the heat required to evaporate a pound of water at the usual receiver pressure is nearly twenty times that required to superheat a pound of saturated steam at that pressure up to 100° F., it follows that if the heating coils in an interheating receiver were called upon to dry out steam received from the high-pressure cylinder containing five per cent of moisture, the entire superheating effect of the heating coils would be lost if the rate of transfer of heat per square foot of heating surface remained the same. This effect is lessened somewhat, though not materially, by a slightly higher rate of heat transfer due to the moisture in the receiver steam. From this it is evident that the receiver should be so arranged that water in the steam exhausted from the high-pressure cylinder is trapped away and not re-evaporated by the superheating coils; inattention to this point is a probable cause of failure in many interheating receivers. Any evaporation of water in the receiver steam is analogous to running a single cylinder engine with steam at an initial pressure of from 10 to 15 pounds above the atmosphere and generated in the indirect manner described.

A very considerable amount of heating surface efficiently arranged is essential to the success of any interheating receiver. The rate of transfer of heat from steam at boiler pressure to steam at receiver pressure is less per square foot of heating surface than in a boiler with water on one side of the tubes. This makes it necessary to use a large receiver well filled with heating coils and so arranged as to secure circulation and avoid dead ends. Any interheating receiver provided with merely a jacket for heating the receiver steam is worthless. In short, unless an interheating receiver actually superheats the receiver steam as described, it is a disadvantage.

One prominent engine building firm who always provide interheating receivers of large capacity filled with seamless brass or copper heating coils, report quite a uniform rate of heat transfer per square foot of heating surface, as the results of over twenty acceptance tests made by purchasers. In the cases where tests were made on the same engines with and without interheating receivers in use, and with from 50° F. to 100° F. superheat in the steam entering the low-pressure cylinder, a net saving in the rate of steam combustion of from 5% to 10% was obtained with saturated steam supply. In stations where superheated steam is supplied to the high-pressure cylinder, the corresponding saving is from 3½ per cent to 5 per cent. For engines of longer stroke or those from any cause more efficient, considered as heat engines, the saving is less than with less efficient engines. Also the saving at light loads is more than at full load, as might be expected, and has the effect of flattening the curve of steam consumption at light loads. The percentages of saving just mentioned refer only to the steam supplied to the engines. Under regular operating conditions, when the hot water of condensation in the heating coils is returned to the boilers there is an additional saving in the rate of heat units per minute supplied to the feed water per indicated horse-power developed in the engine, and, therefore, in the coal burned per indicated horse-power; this amounts to from one per cent to two per cent.

THE MECHANICAL STOKER AND THE HUMAN OPERATOR.

BY EDWIN YAWGER.

Much of the literature on stokers and on combustion in general consists of records of various performances, in which, as a rule, some one feature is prominent and others more or less ignored. A vast majority of boiler trials are utterly unreliable, and even the most reliable contribute little assistance to commercial judgment. Mr. Bryan Donkin, in his book "Heat Efficiency of Steam Boilers," gives a careful analysis of 425 boiler trials. His conclusion from this array of data is best given in his own words:

"When making these summaries, the author at first thought he might be able to draw from them the conclusion that some one type would prove to be more economical than another. It is quite clear that much depends upon how a given boiler, of whatever type, is worked, with clean or dirty surfaces, good or bad combustion, etc., than upon its form, internal or external fires, water or smoke tubes, or the particular way the differently shaped heating surfaces are presented to the furnace and hot gases."

When 400 trials, carefully selected and analyzed, fail to produce any general law, it is evident that another point of view is necessary for broad practical conclusions. Leaving out, then, the question of detailed tests, it will be the object of this paper to present some of the general considerations that bear on the art of combustion of fuel in boiler furnaces.

The mechanical stoker, as a machine, must possess many points of excellence in order to contribute fully to net commercial economy. First and foremost, it must be so designed that it will continue to supply heat to the boilers in spite of accidents or unfavorable conditions of fuel and service. If heavy clinkers form they should be capable of easy disposal. If the actuating mechanism fails, it should be possible to continue firing by hand manipulation. If grates break it should be possible to replace them without drawing the fire. In addition to these primary requirements are numerous details that must be worked out in all their relations before the full measure of fuel and labor economy can be realized.

I believe that next to the matter of continuous operation, the most important feature of furnace design lies in the control of the air for combustion. A noticeable thing about records of boiler trials is the general lack of uniformity of results under apparently similar conditions. Unfortunately, the factor that enters most largely into this variation is seldom recorded, namely, the relative amount of air consumed. In furnace combustion the fact is often ignored that air is a fluid with a definite specific gravity and a consequent inertia.

No one would expect water mains to be efficient if constructed with diversified cross sections, sharp turns, and odd corners. Yet it is common to build furnaces in which the gases meet with improper deflection, unnecessary obstruction and restricted passages. Sometimes the ash-pit and its doors are arranged in such manner that the air by its inertia seeks passage through a restricted area of the fire, usually the rear. I have in mind one case where a hopper-bottom ash-pit being open at the front furnished the principal channel for incoming air, which was directed against the rear of the fire, thus causing air-holes and a reduction in capacity and efficiency. In some cases a great loss in draft efficiency is caused by the clashing of burnt gases as they issue from various boilers into the smoke connection. I know of a case where two boilers were fitted with a vertical uptake extending over both boilers. An increase of 25 per cent in the efficiency of the draft was accomplished by placing a partition in the uptake, to separate the gases issuing from adjoining boilers. It is a matter of common observation that there is frequently a considerable variation in draft in different furnaces where a number are connected to the same stack.

When the furnace is hand-fired, all the losses due to the improper manipulation of the air supply are rendered much greater. An indication of this can be obtained by noting by means of a gauge the variation of draft in the fire chamber during a cycle of firing.

I believe it is the practice of boiler manufacturers to establish a fixed arrangement of baffles. The furnace specialist goes further than this, and arranges the baffles to conform to the nature of the service, and the amount of draft in the particular case.

Accessibility is a prime requisite, and that stoker will give the best service in which the condition of the fire can be seen and obstructing clinkers dislodged without the opening of doors.

In view of the prevailing tendency toward the use of large boilers, stoker design must permit of a corresponding expansion of grate surface. In many cases 500-h.p. or 600-h.p. boilers, instead of being fitted with the proper amount of grate area as determined by the draft and weight of coal to be burned, are expected to give results on a restricted grate, simply because the design does not permit the proper area.

The data at hand on the question of durability offer, if possible, a wider range than above indicated for boiler trials in general. The peculiar thing about reports of stoker repairs is that the records cover only the two extremes of experience. In a few plants the small cost of repairs being a matter of pride, a segregated record is kept of stoker repairs. In other plants, more unfortunate in design and operation, excessive repairs are often reported. The range in this respect varies from half a cent or less per ton fired, to 12 cents in extraordinary cases. In the large majority of plants between these extremes there is no record available.

It should be noted that the life of a boiler and a furnace should be logically reckoned not by the year but by the gallons of water evaporated and the number of tons of coal burned.

Other questions of furnace design no doubt have two sides, with advocates for each. A number of makers construct furnaces calculated to reject the refuse continuously and automatically, the argument being that this reduces the labor required and adds to the effectiveness of the operation. On the other hand, it is claimed that continuous discharge will carry over a considerable amount of combustible when fires are forced, while with light firing there will be a thin zone in the fire near the discharge point that will admit an excess of air; also that large clinkers will occasionally fail to pass through an otherwise automatic discharge.

The extent of the fire-brick arch over the fire in furnaces operating with progressive feed is sometimes subject to discussion. The presence of an arch sufficient to reflect heat on the fuel until it is well coked is always recommended. It is argued, however, that the external fire chamber, with its full-length arch, throws back all of the radiant heat upon the fire, thereby increasing the rapidity of combustion and insuring its completeness. Other authorities state that it is better to expose the heating surface promptly to the highest possible temperature, to this end making use of a large proportion of direct radiation. Rankine states that about one-half of the total heat from the combustion of coal is given up in radiation. The open fire, therefore, would project a greater quantity of heat against the first row of tubes, with a tendency to intensify evaporation at that point. Experiments made by the Northern Railway Company of France showed that evaporation around the fire-box of a locomotive boiler averaged seven times as great per square foot of heating surface as the rate in the flues.

There is no increased danger to boiler tubes by reason of high temperatures. The rupture of a tube in invariably due to some cause within itself, either a flaw in material or the presence of scale sufficient to interfere with the releasing of steam. With these facts in mind, and with a view to reduce as far as possible the loss by external radiation and air leakage, it seems the logical thing to design an arch deep enough to insure the absence of combustible gases in the flues, at the same time permitting a liberal amount of direct radiation.

Judging from the number of 60-foot stacks in use, especially in steel works, there would appear to be a wide difference of opinion on the subject of draft. If I were asked to specify a single improvement in furnaces that would net a greater saving than any other, the reply would be "double the height of all the stacks now in use." Intensified draft will work wonders. First, it will permit the burning of more coal per square foot of grate, thereby increasing furnace temperature. The burning of more fuel per square foot of grate surface, and the consequent high temperature, is in itself an element of economy, illustrating one of the fundamental laws of thermodynamics, which states that efficiency is dependent on the range of temperature in the working medium. Second, it will make combustion complete at a point nearer the coal; that is, the flame will be shorter, and the excess of air will be less. This condition is due to the fact that a strong draft rushes among the fuel at high velocity, causing a more intimate mixture of air with the inflammable gases. Third, the same volume of gas at the same temperature will give up more of its heat when passed rapidly than when passed slowly over the same heating area. Many experiments have been made to determine a law governing the effect of speed on the liberation of heat from gases, but the results are variable. All agree, however, that the effect is important.

It is plain from this that the stack or draft apparatus has a function not usually accorded to it; namely, that of overcoming friction in gas passages induced by high speed of gases, the result will be a reduced capacity and a higher stack temperature.

Lack of space forbids taking up other points that are quite well known but often overlooked. For instance, that soot is more fatal to economy than is scale, but not so fatal to boilers, and that under no circumstances does water do duty as fuel.

It is common experience that no part of a power plant is subject to so much neglect as are the boilers. The reason for this lies in two inevitable weaknesses of human nature, namely, a reluctance to perform a dirty and disagreeable task, and a reluctance to perform any task when its results are not apparent to the observation.

An engine operator may build up a reputation by giving such attention to his engines that they will not offend the eye or the ear of the observer. The chances are that if his engine looks clean and runs quietly, it is in fact in good order; but the external cleanliness of a boiler would argue little as to the absence of scaled tubes, soot-choked passages or broken-down baffles.

Some years ago I became partly responsible for the operation of a large mechanically fired plant in Pittsburg. There were 16 boilers in the plant, and I was asked to determine why it seemed impossible to secure sufficient steam for the engines. I made a brief examination of the boilers, and found that the stack draft in the different batteries ranged from 0.45 inch to 0.7 inch of water, and that stack temperatures varied from 450 degrees to above 700 degrees. The general condition inside the furnaces seemed obvious. I agreed with the management to pick out a man who would enter their employ and have full charge of the boiler plant, with the expectation that a change would soon be apparent. An inspection by this man showed that in some cases soot had accumulated in such quantities as to choke the gas passages. This explained the low draft and temperature in some of the stacks. In other cases the baffles were broken down and displaced to such an extent that the gases made practically one pass through the tubes and escaped at high temperature. This gave the key to the other extreme stack condition. It was found, by a little close observation, that the attendants reported the external cleaning of the tubes without going through the formality of doing the work. A short period of personal supervision served to put the plant in such condition that steam was easily supplied by 14 boilers instead of 16. This happened in a stoker-fired plant; it would have been worse in a hand-fired one, because the same human nature would have been there, only more of it. It is evident that such delinquencies on the part of attendants work equally disastrous results, whether the plant is stoked by hand or by machine.

There is another phase of human nature that has an important bearing on the comparison of hand and machine firing which probably furnishes the stoker manufacturer with his strongest argument in favor of the superior fuel economy of the mechanical stoker. It is the well-known fact that there is a wide variation in the efficiency of individual firemen in the actual manipulation of the fires. During the World's Fair I was called upon by the judges to conduct some comparative economy tests on traction engines, for the purpose of determining the fuel economy of boilers and engines combined, when running at constant load, the furnaces being fired by the manufacturers' expert firemen. In five engines tested there was a variation in results of about 15 per cent. The steam distribution and the furnace and boiler design were quite similar in all five engines, and it would be safe to assume that their inherent efficiencies would not vary more than 5 per cent. The further difference, therefore, of 10 per cent should be charged to the variation between expert firemen.

One universal result of the substitution of mechanical for manual methods consists in a greater uniformity of product, and from the nature of the operation it is possible to maintain a stoker at or near its highest efficiency. To obtain this very desirable condition it will be necessary to start right by making a competent engineer responsible, not only for the selection of the machine, but for the unity of design of the entire furnace, from ash-pit to top of chimney. The responsibility is often assumed by stoker builders, and some of them refuse to make an installation unless full and satisfactory information is furnished covering all the essentials of the furnace.

To maintain a boiler plant at its highest efficiency is not a complex problem, but it requires constant and intelligent supervision. It is its capability of responding to intelligent supervision that renders mechanical stoking superior to the human kind. The functions of the machine are varied, when necessary, by positive adjustments, and changes in adjustments can be governed by definite rules easily within the comprehension of the dullest operator. I should say in general that any chief engineer of a station, who himself is capable of operating successfully a mechanical furnace, can, with a reasonable amount of attention, secure uniformly good results throughout a large plant.

A daily inspection of the fires will assist as much as anything, remembering that a white-hot fire in an indication of all-around economy.

Recording instruments of various kinds will be found useful, especially in mechanically fired plants. Probably the most useful record obtainable in connection with furnace operation is a record of the amount of air supplied. With the uniform conditions due to mechanical stoking, such a record gives a fair indication of the degree of efficiency of the furnace. This record is obtained in many plants by an apparatus for the continuous analysis of flue gases. The use of a draft gauge, attached permanently and showing the draft in the fire chamber, will give an approximate idea of the amount of air consumed. A diminution in draft at this point indicates air holes and an excess of air, while a great increase will indicate too great a thickness of fire and the probable presence of carbon monoxide in the flue.

An expert stoker fireman, in running a test, will keep his fire gauge at that point which indicates the proper thickness of fire.

Many reports find their way into print condemning wholesale the use of stokers, and there are circulated many reports of expensive installations being placed on the scrap pile. It is just possible that in some of these latter cases the mistakes occurred not in the purchase but in discarding the stokers without making sure that a correction in some other part of the system would not have removed the difficulty. Misfit installations are fortunately decreasing in number, and there are now millions of horse-power of boilers machine-fired in the United States.

[The foregoing is an abstract of a paper read before the Boston convention of the National Electric Light Association.]

THE COST OF WATER AND ELECTRIC POWER.

BY GEORGE E. WALSH.

The relative cost of power for electrical purposes differs so widely in various parts of this country and Europe that a study of records of different important plants has in recent years become an essential factor in an engineer's equipment for his work. Factory and mill economy of every description primarily comes back to the first step of generating power. Fuel, labor, water, oil and repairs are all a part of this question. The cost of power must differ because of the difference in the cost of fuel and of water rights, but gradually through comparison of data and methods employed in different parts of the world a standard of cost is being reached. Until close attention was paid to the work of systematically keeping steam, water and general station records, it was impossible to eliminate many of the factors of loss and waste. By locating the cause of waste it has been possible to lessen the losses, and the economy of operation thereby effected has been of far-reaching importance.

As the leading country of the world in the development and utilization of water power for electrical purposes, the United States should stand at the head in the matter of economical production of horse-power for factory or mill purposes. We have some million and a half horse-power developed from water in this country against France's half a million and Norway's quarter of a million. But even these great totals represent only a small fraction of the water power that might be developed in any of the countries through the utilization of water courses. The aggregate power of our own streams is so great that it is impossible to forecast their ultimate improvement. In Africa, South America, India and Canada there are likewise immense water courses that can be utilized for electrical purposes that will make the present development of Niagara appear small in comparison.

A study of the cost of water power in France indicates that the variation is extreme, more so than in almost any other country. This is partly due to the physical conditions of the country, and partly to the methods employed. Experiments with new forms of turbines, water wheels and generators are constantly being carried on there, and to include the results obtained from them in the records brings the cost of power up to high figures. Thus the official cost of a water power plant in France is estimated to vary from $21.40 to $150 per horse-power. When the first turbines were installed at Geneva the effective horse-power cost $300; but when the rest of the plant was finished, and the new units improved, the cost was reduced to $95 per horse-power. Notwithstanding this, the average cost of the plant is estimated at $135 per horse-power.

Consideration of other French plants will show that the cost of water power in that country is, on the average, excessively high from an American point of view. At Vonvray on the Rhine, water power was developed and sold at a total cost of $160 per horse-power for the first 2000 horse-power, and $55 for the second 2000 horse-power. This big reduction indicates that the installation of large units is an important factor in the ultimate cost of delivery of power. A small plant is thus hardly of any value for comparison with a large one.

All through France and Europe the charges for water or electrical power differ widely; but this is not always a sure sign that the cost of generating the power is so much greater in one place than another. The exorbitant charges in some French cities for power are well known, and some towns have driven from their precincts plants that depended upon cheap electrical power for their operation. To show what can be accomplished through the improvement of plants under modern conditions, the cost of development of 3000 horse-power at Vallorbe amounted, according to the capital expended, to only $19.45. On the other hand, the yearly rental of power at Lyons is $90 per horse-power, while in one plant in the same city the highest capital expenditure amounted to $420 per horse-power developed.

In Switzerland the cost of water power is relatively smaller than in France. The physical conditions of the country are the chief reasons for this. The streams and waterfalls of Switzerland furnish an abundance of power for large development, and the engineering schemes that have utilized some of these mountain water courses have been up-to-date in every respect. While the average for the country is placed at $30 per horse-power per year, there are numerous plants that furnish it as low as $20.

In Germany and England the cost varies almost as greatly as in France; but there are effective plants that are prepared to furnish power from $21 to $45 per horse-power per year. The charges for power in some of the factory districts of England are remarkably low considering the engineering difficulties and heavy expenditures of capital to secure effective results. Germany has made more progress than any other nation in using the best machinery and turbines to overcome natural physical disadvantages of the country.

In this country power from hydraulic plants is delivered cheaper than anywhere else in the world. At Columbus, Ga., in the great cotton mill district, electrical power is delivered at the secondaries of the consumers' transformers at the low rate of $15 per horse-power per year. Moreover, the transformers are furnished by the power company, so that the expense of their installation is not included in the consumers' capital expenditure. Power at this rate is supplied to consumers using 1000 horse-power or over, and the contract allows it to be used sixty-six hours per week.

To Niagara one turns naturally to secure data for comparison with other parts of the country. The charge for electrical energy there differs a good deal according to the amount used. The chief object of the Niagara development was to furnish current in large quantities and at little cost; the small consumer is consequently at a disadvantage there. The large consumer finds charges scaled according to his needs, and in such a way that no other region of the world is so well suited to his work; he can secure current at much less than half the rate to the small user. Thus a plant using 1000 kilowatt-hours per month or less is charged two cents per kilowatt-hour, while the consumer of 80,000 to 200,000 kilowatt-hours receives his power at the nominal charge of 0.64 of a cent per kilowatt-hour.

The development of water power along the line of the Canadian border has also been carried out with the idea of encouraging the establishing of groups of large manufacturing plants dependent upon electricity for their operation. The remarkable success of the Niagara people in building up new industrial centers, and in establishing entirely new groups of industries through the cheapening of electrical current for plant operation has naturally stimulated other capitalists to develop streams and falls that offered favorable conditions. At Massena the installation of large electrical units has produced a duplicate of Niagara's history. Already power is supplied there to dozens of plants at a cost not much different from that charged by the Niagara station.

At Kakabeka Falls, twenty miles above the town of Fort William, Ont., where the river by the same name plunges over a precipice 125 feet high, a company is now constructing a plant which will supply electrical power on a small scale at $18 per horse-power per year. A contract has been made with the town of Fort William, and the company evidently sees its way clear to making a profit on the power furnished at the low charge mentioned.

So far the cotton mills of the South have probably been most favored of any plants outside of the Niagara and Massena districts in obtaining cheap electrical power for operation. The use of the electrical current there is consequently increasing steadily. This is one reason for the wonderful prosperity of the southern mills in recent years, and the New England mills that have had to compete with them are gradually adopting electricity for the same purpose. The loss through the drying up of streams for several months each summer is enormous in New England. By systems of storage reservoirs on the streams near their source, so that power can be transmitted electrically to groups of cotton mills as it is needed, this annual summer loss through closing down or generating power by steam can be eliminated from the problem. At present the average cost of horse-power per year for the New England cotton mills is two or three times as great as the rates at which the Southern mills obtain their power direct from electrical power plants. Even with coal and other fuel at the lowest market rates, the summer cost of generating power is so great that the average for the year is increased considerably.

BOSTON CONVENTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION

The twenty-seventh convention of the National Electric Light Association was held at the Hotel Vendome, Boston, Mass., May 24, 25, 26 and 27. At the opening, about 400 delegates were in attendance in the hall. President Charles L. Edgar delivered an able address which was listened to most intently by one of the largest gatherings that ever witnessed the opening exercises of a convention. He referred to the fact that he had been one of the attendants at the former convention in 1887, as the guest of Capt. Brophy, when he visited the old Thomson-Houston works at Lynn, Mass., when the entire number of men employed was not equal to the number now in any one of a dozen departments. At that time the Boston Edison Company was the possessor of one small station, with a total load connected to its overhead system equal to the fortnightly growth of the present year. Referring to the general growth of the central station business, as represented by the members of the association distributed throughout the United States and Canada, he found that the number of electric light stations has increased during these seventeen years more than nine fold.

Mr. Edgar recommended, in view of the fact that a large number of small central stations have been displaced by a smaller number of large stations, that the by-laws of the association be amended so as to add another class of membership, consisting of individuals to be known as junior active members. He also recommended that the association establish permanent headquarters in the Union Engineering building when that is completed.

The report of the Committee on Progress was presented by Mr. T. C. Martin, chairman, and contained some very interesting statistics. It showed that in 1902 the aggregate station capacity of the United States was 1,205,148 kilowatts for the lighting plants, and 898,362 kilowatts for the railway power houses. The advancement in the construction of electrical apparatus was also pointed out, and the new types of apparatus recently developed mentioned. Following the presentation of Mr. Martin's report, a paper on

A Three-Wire, 500-Volt Lighting System

was read by Mr. Walter I. Barnes. This paper is abstracted very fully on another page. The discussion of the paper by Mr. Barnes was quite extensive, covering principally the subjects of grounded distribution and the twin arc lamp used on the Providence circuits. Mr. Junkersfeld expressed doubt if a 250-500-volt system has any advantage over the 125-250-volt system. In the incandescent lamp system there is a considerable difference in the energy loss, owing to the use of low-efficiency lamps, and the arc lamp situation is even more serious. The meter losses are double and the meter slip in the course of a year should amount to a very considerable item. While the difference in the investment required may offset these disadvantages, the adoption elsewhere of the system should be a matter to be very carefully considered. Even under circumstances where it might appear particularly adapted the straight alternating-current system would be a serious competitor. Mr. Alexander Dow thought that with the neutral earthed at different points there would, in towns where there is an electric railway system, be a considerable flow of railway current through the neutral circuit of the lighting system. In a case which came under his observation where two earths were on the neutral three-wire system about 8,000 feet apart, there was a maintained difference of potential of 10 volts during the evening peak of the electric railway load, this resulting in serious disturbances of regulation and necessitating a special provision for balancing the three-wire system at different points. At times in such cases the current may be so large as to seriously heat the conductors.

E. H. DAVIS.
President National Electric Light Association.

Mr. Woodward said that in Providence the lead sheaths of all cables are bonded together in every manhole and there is in every manhole a ground plate bonded to the sheaths and to the copper neutral. In several years' operation no trouble was met with from railway current except in one section of the city very near to a point where the railway cables cross the river. Replying to Mr. Junkersfeld criticism, he said he understood that by "slip" was meant unaccounted-for meter current, and he failed to see how there would be any more slip with 500-volt meters than with 250-volt meters. When it is considered that a single sub-station with a 250-500-volt, three-wire system would cover sixteen times the area that could be supplied from a sub-station operating at 125-250 volts, it would seem a system using the higher voltage would be the better. As to alternating-current competition, he did not see how all classes of motors and all classes of lighting could be supplied with alternating currents at all times, he did not know of a single central station supplying a large area where variable-speed motors are used which has confined itself to alternating-current supply alone. Mr. H. L. Doherty, referring to the matter of meter slip, said that since the torque on the meter is proportional to the amperage and as current is supplied at a higher voltage, the slip would be doubled. As an example of what meter shunt losses may mean, he cited an alternating-current circuit at Madison, Wis., where the shunt meter losses amount to more than the core losses of the transformers. Mr. P. G. Gossler, referring to the wiring of the Union Trust Building in Providence, the frame of which is used as a neutral conductor, asked what the practice was in buildings not having metallic frames. In reply Mr. Woodward said that in these cases a copper neutral would be run.

The Luminous Arc

was the title of the next paper, which was read by the author, Mr. W. A. Holmes. The paper described a new form of arc lamp in which a magnetite electrode is used instead of the usual negative carbon and a copper block instead of the usual positive carbon. The lamp is described fully in another part of this issue. According to the author of the paper, a magnetite lamp requiring 320 watts gives somewhat more illumination than an ordinary 340-watt open arc or a 450-watt enclosed-arc lamp. With ½-inch magnetite negatives, an average life of 100 hours has been obtained in the Newton (Mass.) plant. In the ensuing discussion, Mr. Holmes said that there was practically no deterioration of the copper electrode, and that the citizens were very much pleased with the illumination obtained.

The Committee on the Standard Rating of Incandescent Lamps, Dr. Louis Bell, chairman, then presented its report, in which it was stated that at present primary standard lamps can be procured from more than one concern and in general the conditions relating to standardization of lamps have become such that it is hardly necessary to make an extended report. Dr. Bell felt that the work of the committee was pretty much accomplished when standard lamps could be easily obtained and a general understanding was arrived at as to what would be desirable in the rating and measuring of lamps, and consequently asked that the committee be discharged. He recommended that in the case of reports of technical character there should be closer co-operation between members of the association. A proper method of doing work of this kind would be to send to all members of the association a circular asking for detailed statements of conditions as they find them, and the answers should then be digested and printed as a confidential document, so that every member of the association would know what the other members were doing. At a following convention a special or general committee could report on the data thus obtained and every one who had participated in gathering material for it could then discuss the situation to the best advantage.

Mr. Robert Howes then read a paper on

A One-Hundred Mile Transmission Line

which was substantially a description of the transmission plant of the Washington Power Company, Spokane, Wash. The pole line is 98 miles long, from the power house to the farthest sub-station, with three short branches. It transmits power at 45,000 or 60,000 volts, according to conditions, the step-up transformers having taps which permit this. On leaving the power house the line passes along the city streets for 3½ miles on poles ranging from 45 to 85 feet high; wherever it crosses other lines, grounded wires are strung over the other lines several feet below the transmission line. In crossing a swamp, each pole is set in a "socket" formed by the upper ends of five piles, the central one of which is driven six feet lower than the other, thus forming the socket in which the line pole is firmly clamped with heavy iron bands. No. 2 B. & S. medium hard-drawn copper wire is used. At present unity power factor is usually reached with a load of 1500 kilowatts, the current in the line being then about 18.5 amperes. The line has been in operation for over seven months, during which time the circuit breaker has been tripped eight times. In two cases this was caused by accidental short circuits on the line made by the company's workmen; in four cases the cause was a short circuit on the secondaries of customers, and the other two cases were from unknown causes. The total time power was cut off by these troubles was 32 minutes.

After reading his paper, Mr. Howes stated that since it was written they have succeeded in holding the voltage at Spokane practically steady, there being a variation not to exceed ¾ volt above or below normal on a 116-volt basis, and at the far end of the line the variation was cut down to a trifle over one-half. This was accomplished by means of the installation of a voltage regulator. A controller was then installed on the induction motor at the far end of the line, which again cut down the variation one-half. In reply to an inquiry he said that power had never been cut off except to cut in sub-stations, at which times advantage was taken of the opportunity to renew insulators which have been broken by boys throwing stones and shooting rifles at them, making targets of them at rifle practice. In reply to another inquiry he said that they have had a number of severe lightning storms, which are much more frequent in that locality than in the Eastern and Middle States, but they had never experienced any trouble from lightning. During one storm, however, the insulation of a transformer for operating high-tension circuit breakers in the sub-stations was punctured, which caused a shut-down of ten minutes. This was just before another shut-down of nearly an hour caused by a road supervisor putting several pounds of dynamite under a stump of a tree and blowing it skyward through the wires.

Dr. Bell called attention to the fact that people apparently expect of induction motors a greater degree of immunity from troubles produced on the line, and with others that motors are heir to than in the case of direct-current motors. Large induction motors should have the starting rheostats very carefully designed and this is usually not done, the lower steps of the starting rheostats in three cases out of four not being made for the fine gradations that are necessary. With proper attention to the starter relatively little trouble will be encountered with large induction motors. He believes it advisable to run a little under unity power factor all the time, never giving the current a chance to become leading and thereby introducing oscillatory factors, with magnetizing and demagnetizing action on the generator acting in quicker succession in response to changes in load.

A somewhat elaborate paper was next read by Mr. George N. Eastman on

Grounding the Neutral on High Potential Alternators,

in which the author presented a mathematical demonstration to show that the advantages that may be obtained by insulating the neutral of a high-tension alternating-current system from the earth will be more than offset by the liability of developing abnormally high potentials relative to the earth. The paper was based on a consideration of the three-phase, four-wire system of the Commonwealth Electric Company, of Chicago, and was illustrated by diagrams showing the voltages obtained with wholly insulated and neutrally grounded circuits. The author expressed the opinion that a proper method of grounding the neutral of generators is through as low a ground resistance as can possibly be obtained, in this manner fixing the maximum potential which can be obtained between a system and ground at the normal potential which will exist between the neutral of the generator and its phase terminals. The systems of the Chicago Edison Company and the Commonwealth Electric Company have been operated with a grounded neutral for a period of four years, during which they have apparently been entirely free from the high-potential break-downs that have occurred on other systems of a similar character entirely insulated from the ground.

Mr. Hallberg said that the Cincinnati Gas and Electric Company had operated a system during the past four years similar to that referred to in the paper and with unquestioned success from the practical point of view. He considers it to be by far the most simple and reliable system, and the regulation seems to be everything that could be hoped for. In Cincinnati there has been practically no trouble from lightning, the neutral, if anything, protecting the system from lightning discharges. He recommended, however, that since the primary neutral is grounded all secondaries should also be grounded.

The Organization and Equipment of an Arc Lamp Department

was the title of an interesting paper read by Mr. Samuel G. Rhoades, of the New York Edison Company. Mr. Rhoades' paper was based on his experience with the arc lamp department of the New York Edison Company. The paper contains reproductions of seven printed cards and slips used in the system, and gives illustrations of a carbon cutter and punch for cutting washers, an inner globe washing machine, a "shepherd's crook" lamp post and a supply wagon. The method of keeping track of every detail connected with an arc lamp system is described, and the duties of the various classes of employes are detailed. In turning on and off direct-current multiple lamps boys, preferably over fourteen years of age and almost exclusively school boys, are employed, receiving $2.50 weekly for forty-five minutes' actual switching work both night and morning. Three men in charge of the boys cover the entire city of New York.

In the discussion of the paper by Mr. Rhoades it was brought out that during the past several years the arc lighting business appears to have come to a halt. Mr. Gilchrist, of Chicago, said that recently he had noticed a tendency on the part of the general public to use arc lights again, but he thinks this is due to a more strenuous effort on the part of central station people on account of sharp competition from various types of special gas burners on the market, and which are strong competitors to the arc light. Mr. Rhodes said that the advance made in New York has really been the work of the contract department. The lighting engineer is a new departure; when trimmers report that any customer's lamps are acting badly the lighting engineer or one of his assistants is around the next day to remedy any defect. Many people have changed over from the Kitson and Humphrey gas burners, the operation of both of which, especially in the winter time, is very bad. He considers the 3.25-ampere lamp very useful, for if the customer does not want to pay for a 5-ampere lamp he will probably be willing to take a lamp of the lower consumption. Mr. Douglass Burnett, of Baltimore, said that there is little difficulty in getting arc light business now when the solicitation is properly done. The customer should be assisted in locating lamps and sometimes given sketches with a general outline of a scheme for his lighting. For example, he may be advised that for the interior of his store he requires a 5-ampere lamp for every 300 square feet of floor space, the lamp to be located with the arc about 12 feet above the floor level. For the windows incandescents should be recommended. Arc lamps in the interior of a store will show goods better than anything else to customers, and he cannot produce a brilliant effect in front of the store with interior incandescent lights. In fact, the prospective customer should be advised on every point calculated to make his lighting most effective. He considers that the problem still remains as to how to develop the series arc lamp service.

Mr. Rhoades said that while in the case of large contracts the New York Edison Company does not care for the lamps, yet they keep their eye on the installation and freely offer their service whenever it appears to be called upon. As to maintenance of arc lamps, one trimmer at $14 a week, seven days, will take care of 650 lamps; in the repair shop one man at $3.50 a day and the rest at $2 per man, will take care of 2000 enclosed lamps. Mr. Burnett said that in Baltimore he also used night linemen in the various districts, who were available in case of either an open or a grounded circuit and for switching electric signs on and off again. In reply to a question it was stated that the New York Edison Company and the Omaha Electric Light Company furnish diffusers free to their customers, and Mr. Fleming stated that the General Electric Company will adapt its diffusers to any type of lamp.

Mr. James I. Ayer read a very interesting paper on the subject of

Electric Heating and the Field it Offers to Central Stations,

in which he pointed out that electric heating apparatus may be used to advantage under certain conditions and when intelligently handled; for example, small heaters, used intermittently and turned off when not actually in use. He enumerated a considerable list of such devices, which are supplied with connector plugs to fit lamp sockets and do not need to be in circuit more than ten to thirty minutes, making but a small addition to the monthly light bill. Concerning electric cooking, he said that electric cooking apparatus operates at an efficiency of about 70 per cent, while gas averages only about 15 per cent time efficiency in domestic kitchens. Assuming gas to average 700 heat units per cubic foot, the drop in the circuit between the meter and electric cooking utensils to be 1 per cent, the efficiency of use to be 15 per cent for gas and 70 per cent for electricity, he showed that in order for electricity to compete with gas at equal rates the following prices would need to be quoted for electric service.

Per kw.-hour.	Per 1000 ft.
5.67 cents, if gas is	$2.50
4.54 cents, if gas is	2.00
3.4 cents, if gas is	1.50
2.83 cents, if gas is	1.25
2.27 cents, if gas is	1.00

In a family of four or more persons, he said, electric cooking will require from 1 to 1.5 kilowatt hours per day per person; recorded data show an average about 20 per cent below the higher figure. The cost of heating water from 60° to different temperatures, he gave as follows:

One Gallon of Water; Initial Temperature 60° F.

Ultimate Temperature.	Watts used for			Cost in cents with current at		
	10m.	20m.	1 hr.	3c.	5c.	10c.
100° F.	648	324	108	.32	.544	1.088
150°	1488	744	248	.74	1.24	2.48
175°	1872	936	312	.94	1.56	3.12
200°	2304	1152	384	1.15	1.92	3.84
212°	2496	12.48	416	1.25	2.08	4.16

The equipment of domestic laundries, he said, will be found a profitable field by central stations. A family requiring but one iron will need a size using about 500 watts and the service will range from 2500 to 5000 watt-hours per week. It is not possible to do ordinary house or office heating unless current can be supplied at exceptionally low rates. Even for cooking and laundry work, special rates, lower than lighting rates, are essential, but as the load is chiefly a summer day load, specially low rates are possible and the business is desirable. In the discussion which followed the reading of the paper, Mr. Ayer recommended that the policy generally followed with regard to arc lamps be adopted in the case of electric heating apparatus, namely, that heating outfits of all kinds should be provided free by the central station. The average kitchen for a family of from four to eight persons involves a transformer capacity of about 30 amperes and 3 kilowatts. The average demand of a family of this kind is about 20 amperes and 2 kilowatts at the cooking hour, or about two-thirds the house service. Most of the load for cooking is over by 6 o'clock, so that at most seasons of the year it would not coincide with the peak load.

Mr. Alexander Dow, of Detroit, said that in Detroit the peak load is in advance of the general maximum lighting in the residential districts, coinciding with the down-town peak. Electrical cooking would add to the main station peak load, but for winter service only. The cooking load is about two hours per day throughout the year. It does not do to sell cooking apparatus unless it is looked out for. An absolutely clean, smooth vessel is better than the ordinary cooking utensil, and the best one is a type of vessel which clamps solidly to the disk. The conducting cords are a nuisance, and he suggested that they should be passed through a hole in the table as in the case of telephone switchboard cord. The devices furnished by various makers for varying the heats are about useless in the hands of the ordinary kitchen servant. He considers that two heats are practically sufficient—one quick and one simmering heat—and that these can be obtained by a double-throw switch, which when open cuts the heat off altogether. The worst fault to be found with electrical cooking to-day is in the repair bill, which is a very serious matter.

Mr. Arthur Williams spoke of the desirability of circulating among electric light users information relating to electric cooking, and said that the New York Edison Company has recently been doing this extensively. He thinks electric cooking apparatus will never give to the companies a large revenue, since its use is confined to short periods of the day, but aside from cooking the late afternoon dinner in the winter months, whatever revenue comes from this apparatus is additional per kilowatt of installation. This in itself should encourage effort toward installing electric heating and cooking apparatus. In the months of June, July, August and September the load will not come on at the peak, and in view of this it might be well to adopt the English method of making a lower charge for the current used during these months. He considers that every large device connected with electric cooking should have an indicator which cannot be removed and which will show when current is on and off; he has known of cases where the colored lamps supplied with cooking apparatus have been turned out and the current left on. In one case the current was left on an electric heater during the entire summer season in the absence of the owner. He cited a case of a large factory where electric irons are used for making hats; the price paid for current is 8 or 9 cents per kilowatt hour and the cost of this service is almost identically the same as that of the former service rendered by gas. The advantages in the use of the electric heating iron are that the men work faster, thus increasing the output; the factory and the men working there are kept cleaner; the atmosphere is cooler and working with the electric iron is much less fatiguing to the employes.

Lost and Unaccounted-for Current.

Mr. C. W. Humphrey gave an account of the method used by the Denver Gas and Electric Light Company for determining the losses, known and unknown, from alternating and direct-current circuits. The losses are classified as transformer iron losses, primary resistance losses, secondary resistance losses and meter shunt losses. The methods employed by the Denver Company for determining these losses are given in detail, the paper containing reproductions of forms and curves employed in this work. It was found that the greater part of lost and unaccounted-for current was due to thefts. The author cited an instance where, through proper attention to reducing losses, the ratio of sales to output increased from 59.3 per cent to 80.5 per cent. In another case, where a feeder was changed from a 1000-volt individual transformer to a 2000-volt, three-wire secondary network, there was a reduction in transformer iron losses of over 60 per cent. In this instance the sales were increased to nearly the original amount and the transformer iron loss reduced to about one-half the original amount, though the primary and secondary resistance losses were increased considerably through the increase of the output of the feeder. In the case of a principal business feeder the watts per lamp of output remained about the same for the entire year, while the watts per lamp of sales increased during the same period to nearly double. The sales increased from 41.6 per cent to 83.5 per cent, the known losses remained about the same, while the unknown losses decreased from 48.4 per cent of output to only 5.22 per cent. A check meter placed in a district having nine ampere-hour meters and eleven integrating wattmeters showed a loss in the district of 8.1 per cent, not including about 2 per cent wattmeter shunt losses. The larger loss was principally due to the ampere-hour meters, which do not start on less than two to four 16-c.p. lamps.

Economy in Minor Station Supplies.

In a paper with this title, Mr. Edgar B. Greene discussed the care of minor supplies in stations of moderate size. In his station there is a course of training which starts a young man as an apretice either in the steam or electrical side of the plant, and gives him a thorough training in all branches of the work. There is no definite period for this course, the apprentice being promoted as fast as his ability will warrant, there being a distinct understanding that each person must earn his promotion or stand aside for the next man. A number of the apprentices take a course in correspondence schools and this method of education is strongly endorsed. The paper referred to a number of minor economies such as standardizing pipe nipples and valves, using tubing in steam hose for cleaning boiler tubes, and a home-made arrangement for bending tubes was described. A lathe was installed for making simple repairs. The ashes and cinders are carted away free by a railroad company and others having use for them. Arc dynamo brushes are made from strips of hard-rolled copper 0.01 inch thick; four of these are soldered and a phosphor-bronze strip 0.02 inch thick is used as a stiffener. All oil from the engines is drained by gravity direct to the oil house, where it is filtered by a home-made apparatus. Defective coils of arc lamps and Thomson recording wattmeters are rewound in the station, as well as all transformers. In reading the meters the routes of the men are changed monthly, and different men instead of the same man are used for this service. After the inner globes of enclosed arc lamps are washed they are tested on a ground steel plate for the closeness of joint and then fitted to the holders, the lower holder being trimmed in the station. At least three days' supply of inner globes are always in course of cleaning or washing, which keeps two days' supply ready for use. With a new man the average life of the inner globe is about 800 lamp-hours for the first month and afterwards from 1400 to 1500 hours; the number of lamp-hours per carbon is found about 10 per cent shorter with a new man on the first month.

In the discussion of Mr. Greene's paper, Mr. W. L. Abbott, of Chicago, said that he knows of nothing which will introduce discord in the operating force so promptly and so continuously as placing an outsider in one of the higher positions over the heads of men who have worked faithfully for years. He has known of cases where discord thus produced has been so great that it was necessary to discharge the entire original force. Concerning oil filtering, he considered there were two functions to be performed, one to remove the grit and the other to remove grease and water from the oil. By removing the water and grease in the settling chamber, he has found there is no need of a filtering material in the oil filter.

Mr. E. E. Arnold contributed a lengthy paper entitled

Notes on the Internal Combustion Engine as Applied to Central Station Service,

in which, after briefly outlining the theory of the gas engine, he gave data as to test performances and described and illustrated a number of central stations equipped with Westinghouse gas engines. The paper contained a table giving the results of tests for a large number of gas engines of this type.

Test of a 5,500 H.P. Compound Engine and Generator,

was the title of a paper read by Messrs. J. B. Andrew and W. F. Wells which gave the data of a test of one of eleven three-cylinder, 5500-h.p., vertical compound engine units installed in the Waterside station of the New York Edison Company. The method of test is described in detail and much of the data is plotted in the form of curves. The test showed that for outputs of from 2500 to 4500 kilowatts the steam consumption varied between 17.12 and 18 pounds per kilowatt-hour of net output at the generator terminals. The best test showed an economy of 11.93 pounds of water per indicated horse-power-hour or 16.78 pounds per kilowatt-hour. The tests indicated a decided disadvantage in the use of a receiver reheater and steam jacket in this type of engine. The curves show an almost absolute uniformity of economy for a considerable range on either side of the normal rating. Increasing the vacuum from 25.3 to 27.3 inches decreased the water consumption only 0.06 pound, whereas increasing the receiving pressure from 21 pounds to 36.8 pounds, or changing the distribution of load from about ⅖ on the high pressure cylinder and ⅗ on the low-pressure cylinder, to about equal load on all three cylinders, decreased the water consumption 0.25 pound.

Mr. Francis Hodgkinson contributed a paper entitled

Practical Notes on Steam Turbines,

in which, after discussing the principles of this type of prime power, brief descriptions were given of the De Laval, Stumpf, Curtis, Zoelly and Rateau turbines, the remainder of the paper being devoted to the Westinghouse-Parsons type. A considerable portion of the paper was devoted to foundations and power plan designs for Westinghouse-Parsons turbine electrical equipments.

The papers by Messrs. Andrew, Arnold and Hodgkinson, and the report of the Committee of Investigation of Steam Turbines by Mr. Eglin, were discussed together. In opening the discussion, Mr. Ralph D. Mershon said he noted that in the gas engine plant on which Mr. Arnold gave figures, nothing was allowed for relay capacity, and if this were done it would mean a greater investment to the disadvantage of the gas engine. He has found that most gas engine builders rate their engines at or near the maximum load they will carry, whereas the steam engine is rated so as to have a considerable overload capacity. He considers that the gas engine should be figured as having a less efficiency at lighter loads, as compared with the steam engine. Referring to the figures given by Mr. Arnold as to cost per kilowatt of steam and gas installations, namely, $100 and $125, respectively, he thought that the figure for the gas engine should not be under $150 and nearer $175.

Mr. Doherty said that the serious drawback in gas engine development is in securing economical and satisfactory transformation of the heat energy of coal into gaseous energy. Mr. H. G. H. Tarr spoke of the reduction of cost to be obtained in the generation of gas through utilizing the by-products. In one process, if the coal is worth $2.50 per ton, the by-products reduce the cost to the equivalent of $1.50 per ton, these figures being applicable to larger plants of, say, 50-tons capacity in 24 hours and above. A producer using bituminous coal will cost from $17 to $20 per horse-power. Mr. W. R. Gardener suggested that peat might possibly be used to make a producer gas at low cost.

Mr. R. H. Rice, of Lynn, Mass., in answer to a request, gave a description in detail of the Curtis turbine. Up to and including 300 kilowatts this turbine is constructed in the horizontal form and in the vertical form for larger outputs. All large Curtis turbines are made now with four stages. He cited a case where only two reciprocating engines of 500 kilowatts capacity could have been installed in a certain power house, where five turbines of the same size were readily located.

Mr. H. L. Doherty spoke highly of the prospects of the gas engine, and said that to-day practically every authority on thermodynamics believes the ultimate prime-mover will be the internal combustion engine. In his opinion the steam turbine will be left behind by the internal combustion engine, which will unquestionably be the eventual prime mover. To get the best efficiency in the gas engine it should be operated at its maximum capacity, since the losses are 25 per cent of the capacity, no matter what the load. Gas engines cost more per horse-power at the start and the fixed charges are consequently heavier. It is, therefore, desirable to operate the gas engine the longest number of hours, and an ideal arrangement would be to use a gas engine to take care of that portion of the load which is on 24 hours a day, the variable load being taken up by steam engines. He endorsed a statement by Mr. Arthur Williams that the present gas engine is relatively no better developed now than the steam engine was during the life of Watt, and he believed the gas engine has wonderful possibilities ahead. He thought that the question of the gas producer is not receiving in this country the attention which it deserves and which is being given to it in Europe. As to the smaller space occupied by the steam turbine in his work he had found that he could not always avail himself of the lesser space indicated by the turbine without the use of a system of steam piping that would not be good engineering practice. Several methods have been proposed to reduce the space occupied by boilers. One is to have the boilers installed back to back, giving a double boiler room with the firing door on the side, the steam piping being led from one firing alley to the engine room. Another plan is to build the boilers with the firing doors at right angles to the turbine and have short alleys running up to the groups of boilers. Another way is to design a special boiler having little width and considerable depth, this probably involving a vertical boiler. Another method suggested but not looked upon with favor was to put the boiler room on each side of the turbines. As to condensers, Mr. Doherty says he has never been able to satisfy himself that he cannot get a higher vacuum from a jet condenser than a surface condenser, and he hopes next year to have some definite figures on this subject. The question of superheaters is a rather serious one, for it is difficult to control the degree of superheat and the tubes burn out.

Mr. Arnold, in referring to Mr. Mershon's remarks concerning the rating of gas engines, said that these are ordinarily rated at a brake horse-power of 15 to 20 per cent under maximum capacity. Steam engines are rated on their indicated horse-power with, say 50 per cent overload, but the difference between indicated and brake horse-power amounts to considerable, and the actual capacities of the two types of engines approach more closely than would ordinarily be supposed. As a lighting station has ordinarily a 20 per cent load factor, the relay capacity is well taken care of in the way the units are laid out in the case Mr. Mershon criticises. Smaller gas engine units of approximately the same efficiency as large gas engine units, and the smaller gas engines, are notably more efficient throughout their range of load than the steam engine. As to the relative efficiency of the gas engine at light loads, he referred to a curve in his paper showing that at half load the brake thermal efficiency of the engine was 21 per cent, while that of a steam engine of the same capacity would only have a corresponding efficiency of 10 per cent. As to the depreciation and life of a gas engine in comparison to the steam engine, experience points out that the former quite holds its own with respect to depreciation, though it will perhaps be found that it costs slightly more for horse-power repairs than the steam engine equipment, excluding the more intricate designs of multiple-cylinder, releasing-gear steam engines using superheated steam. He cited a lighting station having a 24-hour service equipped with 800 horse-power rated capacity in gas engines in five units, complete repairs for which in the year 1903, including repairs to igniters, cost only $102, or something less than 13 cents per horse-power per year. In reply to an inquiry he said that all plants referred to in his paper are connected with alternating-current generators operating in parallel, and many of the plants are giving a 24-hour service. He referred to a 3000-h.p. gas engine cement plant which operates 24 hours a day and has been in service about four years.

Mr. Edwin Yawger read a paper entitled

The Mechanical Stoker and the Human Operator

which is printed almost in full elsewhere. In the discussion of this paper Mr. C. H. Parker said that the higher the temperature of a furnace fire, the better the furnace efficiency. Flue gases analyzed with low fire temperature show a large excess of oxygen. When the grate combustion is run up to 40 or 50 pounds per square foot rate, the excess air is brought down something like 30 to 40 per cent, and the fire is a dead white. Better economy may be obtained by reducing a grate area and using a greater number of pounds per square foot, and also per square foot of heating surface. Mr. R. S. Hale, of Boston, said that after analyzing a great many boiler tests he had reached the conclusion that, other things being equal, the less draft used the higher will be the efficiency. If it is a question of getting a greater capacity, then of course, a greater draft must be supplied, or if a grate surface is cut down more draft must again be supplied. He disputed the statement of Mr. Yawger that the same volume of gas at the same temperature will give up more of its heat when passed rapidly over a heating surface than when passed slowly. On the contrary, better efficiency is secured by passing the gases more slowly over the heating surface. One reason why the best efficiencies are gained with a low draft is that this implies more careful firing in order to keep up the capacity, and hence reduces the amount of air used, thereby reducing the loss of heat in the waste gases; and since the gas is passed more slowly over the heating surfaces, they give up more of their heat.

The Doherty Medal.

Dr. S. S. Wheeler, chairman of the committee on the award of the Doherty Gold Medal, said that of the various papers submitted on the subject of underground construction, there were two excellent ones, one by Mr. W. P. Hancock, of Boston, and another by Mr. Blood, of the same city. While the paper by Mr. Blood was very good and exceedingly well composed, it was unanimously decided to recommend the award of the prize to Mr. Hancock. Mr. Edgar presented the medal to Mr. Hancock, and said that his career had been passed with the Boston Edison Company, of which he is now general operating superintendent, and the designer of the two station to be visited by the members. In accepting the awarding Mr. Hancock said he wished there were a greater engineering interest in underground construction. The subject is an extremely important one and should be given close attention.

Mr. C. L. Wakefield presented a short paper entitled

Electric Light and Power Plants in Connection With Ice Plants,

in which he gave the result of correspondence with about 50 plants supposed to have an ice plant auxiliary. The results showed that very few of the plants were actually so equipped, and with three exceptions, where there are equipments they have been installed without any particular purpose. In his station a 300-kw., alternating-current plant operates a 100-ton ice-making plant with the addition of one oiler and one fireman to the regular force. The fuel cost per ton of ice varies from 350 to 700 pounds of coal, depending upon the calorific value of the fuel and the manner of its use.

Mr. Scheuck thought that it was a bad plan for electric light companies to operate ice plants or enter into other classes of industry, excepting steam heating, for the reason that it was likely to antagonize municipally influential persons who might be interested in competitive ventures.

Decorative and Sign Lighting.

The report of Mr. Arthur Williams on this subject was presented in a beautifully executed pamphlet containing a large number of views of New York City buildings and interiors, and reproductions of letters printed on toned backgrounds. The illustrations were mostly views of facade lighting of theatres and other buildings, with some views of interior lighting, the most striking being a representation of the Waldorf ballroom on the occasion of the A. I. E. E. annual dinner. The letters are principally reports from electrical companies on the subject of decorative and sign lighting. Following Mr. Williams' report, Mr. La Rue Vrendenburgh presented his report on

Advertising Methods.

This related principally to the methods of advertising that have been employed by the Boston Edison Company. Reproductions are given of a large number of newspaper advertisements and of electrical signs soliciting central station business, and the text points out methods pursued by several of the larger companies in soliciting business.

The reports of Messrs. Williams and Vredenburgh's papers were discussed jointly. Mr. Scheuck said that methods which might pay in large plants could not be afforded by companies in smaller cities. Mr. Williams' and Mr. Vredenburgh's methods were undoubtedly of great efficacy for the large companies, but there were only a few companies in the United States which could afford them. He was connected with several plants in smaller cities, these plants doing both railway and lighting business. He had found one of the best methods of getting new business was to print small booklets and to supply them to metal holders in the street cars each day. In a town of 50,000 inhabitants he had begun with an issue of 4000 booklets a week and had had to increase the number. The booklets contain humorous items interspersed with advertising arguments; he found that people would take these booklets home, and that they had been the means of increasing his lighting and power business. Another method of extending power business is to go to small factories and shops already equipped with motors, but not intelligently so; to re-equip them so as to secure higher operating economy and take photographs of the meter bills before and after the change, using these photographs as advertising material. He advocated making very low rates to stores for electric signs, show window lights, etc., and taking special care to see that the stores maintained their signs and show window lights in good condition. Mr. Scheuck also pointed out that the lighting company's office should be in a good location and well illuminated at night in order to make a good impression on the citizens. Mr Converse D. Marsh disagreed with Mr. Scheuck as to the efficacy of his methods. He thought that methods of getting new business should be the same in character in smaller plants as in large ones, differing only in degree. Promiscuous distribution of booklets he did not consider efficacious. Solicitors could not know who had been reached by the booklets, so that a follow-up system could not be applied; the booklets alone certainly would not bring a man up to the point of signing a contract. Mr. Burnett also disagreed with Mr. Scheuck. He was connected with a company in a city of moderate size and had obtained good results by furnishing free electric signs in order to obtain the resulting business. President Edgar, in response to an inquiry by a member, said that the Boston Edison Company spent 5 per cent of its gross income in advertising and soliciting new business, this amount being about equally divided between the two branches.

The report of the Committee on

Purchased Electric Power in Factories,

consisting of Messrs. W. H. Atkin, chairman; S. Morgan Bushnell and G. W. Brine, gave the result of inquiries made by circular letter concerning the use of electric power in factories. The letters were sent to all of the members of the association and asked for answers to 13 questions relating to the charge for power, kind of factories supplied, increase of power business, decrease of production cost from use of electric power, kind of electric drive, amount of power sold, etc. To 462 circular letters sent out 61 replies were received. Of these 19 reported no sales of factory power, 11 either gave no information or answered but one or two questions, and 31 replied more or less fully. The average increase of power business of 24 companies reporting was 37 per cent, a larger amount of increase than the lighting load. The rates reported range from 2 to 15 cents per kilowatt-hour, the usual range being from 4 to 10 cents. Among the conclusions of the report are the following:

The sale of electric power by central stations to factories has been limited largely to such industries as have to carry on their business in the centers of cities or towns where space is costly and where the trouble and danger of steam engines become large factors. The great industries of boots and shoes, cottons and woolens, usually produce their own power.

Among printers there is a large patronage from "job shops" and a good proportion of the newspaper offices, but practically none from book printers, whose "runs" are long and whose "make-readys" are comparatively short.

The committee considers that the best method to increase business is to educate the prospective customer. Although electric power has been in use for 15 years, it is not yet the first power of which a man thinks when he is about to start a new factory If the central station could have its solicitor on hand to explain the advantages of electric drive over mechanical drive before the prospective customer has purchased his gas engine or steam engine, or made his contract for power from a belt, a great amount of business might be obtained which is lost simply through unfamiliarity with electric power on the part of the power-using public. In this connection it is of the highest importance that the solicitor be thoroughly conversant with different manufacturing processes, and be a man of great power of observation, so that he can take in the situation quickly and give the customer the needed points which will "tell" and turn the scale to electric drive supplied from central station.

After a customer has been secured he should not be left to his own resources, but should be advised as to the number of motors to purchase and their arrangement. Careful attention to the details of installations at the time the motors are purchased will effect economies, and these will go to the credit of the central station service. The customer is naturally quite reluctant to buy several motors, when, so far as he can see, one will do the work just as well; but the solicitor should have at hand facts and figures that will prove conclusively that the extra motors will return a good dividend upon the investment, and that with the individual motor equipment or the group drive, the central station can supply power more cheaply than the customer can produce it himself.

One great point of economy which should be looked after is the use of the electric elevator in place of that operated by steam or hydraulic power. In many factories may be found a slow-speed freight elevator driven by belts from the main shaft. This can always be changed over and connected to an electric motor without calling on the elevator makers and at comparatively small expense. Another important feature in central station service is the facility with which any single department can be run overtime. This often avoids the employment of inexperienced help, and enables the manufacturer to respond more promptly to any unusual demand. Another exceedingly important factor in the advantages of electric power is the ease with which a plant can be enlarged by merely buying additional motors from time to time, instead of taking out and discarding an overloaded steam plant, and putting in a new one at enormous expense, or at least adding long lines of shafting and belting.

The ability to move machines about, taking the tool to the work, instead of the work to the tool, is often a great advantage in large establishments, and this may be done with the greatest facility when tools are directly connected to electric motors. The time saved by this arrangement in shops handling large masses of metal would pay a very large dividend on the investment in motors. The cleanliness of a shop supplied with motors instead of with shafting would be a revelation to one who was not familiar with the results which such a change in power produces.

Heating from Central Stations.

The report of the Committee on District Heating, consisting of Messrs. E. F. McSherman, D. F. Magee and C. M. Maunsell, gave the results of inquiry made among central stations operating steam and hot water systems. Of 100 companies addressed, 52 replied, including 36 operating steam and 16 operating hot water systems. The report gave in tabular form the replies to the 24 questions propounded. The conclusions of the committee were that as a whole it seems clear that the companies now in the heating business are in general making money. Out of the 35 steam systems 31 stated and showed by the figures returned, that they were well pleased with the investment. Out of 15 operating hot water systems, 11 were satisfied and 4 were not. The best financial showing is made by those companies basing their charge on readings by meter and cubic feet of air space, which insist on the use of economizing coils, inspect and supervise the installation of buildings and refuse to connect or give service to poorly designed heating systems; and which keep separate accounts of heating and electrical revenues and expenses, and recognize the value a heating system has as an auxiliary to electric light and power supply. It is at least a coincidence that the companies making the poorest financial showing are those that, from a lack of knowledge of what they are actually doing, are unable to make definite or explicit replies to some of the questions asked.

The important matter of depreciation has not had the consideration that should be given to it; only 21 of the 52 companies reporting have seen fit to provide for this. Most companies report low cost of repairs, one that has been in business for six years reporting only 2½ per cent on mains and services. The question of returning condensation to the power house seems to be one related to local conditions. Very few express themselves favorably on constructing a plant for this purpose, though a few are much in favor of it, probably owing to the local situation. The replies seem to indicate that district heating is now a success and could be made more so if central station managers were to co-operate with the committee for the general good. The paper gave the full text of the replies received from all of the central stations which reported.

In the discussion, Mr. McCabe, in answer to an inquiry, said that of the fifty-two companies that had replied to his inquiries only five or six had made any charge to cover depreciation on mains, etc. One company which had been in the heating business fifteen years charged 2½ per cent to depreciation. Another company which had been supplying heating service for eight years made no charge. Mr. McCabe thought that the depreciation should be taken into consideration, but that it would be small. He also pointed out that the supplying of heating service enabled an electric light plant to get lighting business in office buildings and other large establishments, which, if they had to maintain heating plants, would also operate their own lighting plants.

Office Methods and Accounting.

Mr. Frank W. Frueauff, in his report on office methods and accounting, confined himself to an account of the methods used in the offices of the Denver (Colo.) Gas and Electric Company. The author advocated the plan of apportioning the cost of operation to the class of current made and of separating fixed and variable costs. The expenses occasioned in manufacturing and distribution for any one class of current should be kept distinct from those incurred in another, so that the actual cost of manufacture and delivering arc power and alternating current may be known separately. The cost for any one class should also be separated to show the costs that are fixed as distinct from those that are variable. For example, station foremen, meter department, shop expenses, etc., are practically a fixed expense, not varying notably as the business increases or decreases. Boiler fuel, firemen, lamp renewals, carbons, etc., vary with output, and under a third head may be included meter, arc lamp and service repairs, meter reading expense, collection and office salaries. With the cost for any class of current separated into these three divisions, it is possible to know just what results are being obtained, and this method is particularly valuable in figuring rates to be made to secure new business. For example, in figuring to take on a long-hour burning customer, it is known from the figures of cost that the fixed cost will not be materially increased nor the consumer's expenses, and that only the output cost will be increased.

Standard Instruments for Central Stations

In a paper entitled "A Proposed System of Standard Instruments for Operating Companies," Mr. H. P. Davis, after sketching the desirability of accuracy of central station measuring instruments, and consequently the necessity of reliable standards for calibration purposes, suggested that a remedy for the present unsatisfactory condition in these respects may be offered by the manufacturers of high-grade electrical instruments. The service rendered by manufacturers of such standard instruments could advantageously cover their care and recalibration after they were put in the hands of purchasers. All the conditions of manufacture combine to make the manufacturers of such instruments the best able to care for them thereafter. To render the best service under the plan suggested, the manufacturers of the instruments should make no charge for recalibration and should see to it that prompt return is made to the owners. It might even be found advisable to ask owners to send in instruments to be checked when a considerable period has elapsed without such attention. The owner would be at no expense, except for carriage, and should have no hesitancy in sending his instruments to the maker for attention when desired.

Mr. W. A. Layman read a paper on

Single-Phase Power Motors for Electric Lighting Stations,

which treated the subject under the following heads: Reliability of single-phase motors; comparative cost of insulation of single and polyphase motors; single-phase motors on polyphase generators; single-phase motors for lighting circuits; single-phase motors for high frequencies; the desirability of motor load for central stations; the special value of motor load to small stations; the day circuit as a factor in the building up of small towns, and power rates for single-phase motor service. The discussion of the subject was based upon the assumptions that the single-phase motor, except for variable speed work, is to-day the substantial equivalent of the direct-current motor; that polyphase and single-phase types of motors are not competitive, and third, that simplicity of generating equipment and system of distribution are of paramount importance in the profitable development of central station service.

For large plants having polyphase generators, Mr. Layman suggests that the switchboard be arranged for operating polyphase feeders for all large power and rotary converter service, and single-phase feeders for all general lighting service and for all small power work, the switchboard being such that any single-phase feeder may be switched to either phase of the generator buses. Where sub-stations are employed similar switchboard arrangements should be made for polyphase distribution in large units and single-phase distribution for all other kinds of service. Independent feeder regulation should be provided for all polyphase as well as all single-phase feeders. It is stated that the cost of installation of the single-phase motor is much less than that of the polyphase; that satisfactory single-phase motor service can be gotten from polyphase generators, and that single-phase motors can be satisfactorily operated from lighting circuits. The New Jersey Public Service Corporation and the United Gas Improvement Companies are installing single-phase motors up to and including 35 horse-power, and the Cincinnati Gas and Electric Company is adding single-phase motors of 15 or less horse-power capacity and considering larger installations individually on their merits. In Chicago motors of 5 horse-power or less are required to be single-phase and larger installations are considered individually on their merits. Satisfactory single-phase motors can be made for 125 and 133-cycle circuits. There are a number of instances of central stations giving 133-cycle motor service almost up to the maximum capacity of the plant. The paper includes power rates for single-phase motor service as established in Peoria, Ill., and in Cincinnati, Ohio. In the former place the charge varies from 10 cents per kilowatt-hour up to 100 kilowatt-hours per month to 2.8 cents per kilowatt-hour for 2000 kilowatt-hours per month and over, 10 per cent discount being given on all bills paid within ten days. In Cincinnati the basic rate is 10 cents per kilowatt-hour, with discounts varying from 10 per cent for 100 kilowatt-hours per month to 60 per cent for over 800 kilowatt-hours per month, there being an additional discount of 5 per cent on all bills paid within five days.

Mr. J. H. Hallberg stated that the Cincinnati Gas and Electric Company had had to adopt the policy of declining to connect up three-phase motors smaller than 15 horse-power in order to keep down the fixed charges due to the investment for transformers, meters and accessories. They had found that the use of single-phase instead of three-phase motors within the limits mentioned had effected a very considerable economy in fixed charges and had also enabled the company to supply customers whose service would not have been worth obtaining if it had been necessary to run three-phase lines to them and install three-phase transformers, meters, etc. In the case of elevators and other special machinery requiring heavy starting torque, three-phase motors were still used in all sizes.

Wrinkles.

The "Question Box," originated by former President Doherty, has been supplemented by a new department entitled "Wrinkles," which consists of a collection of notes giving an account of practical expedients, home-made apparatus, etc., devised by central station men. The editor, Mr. Charles H. Williams, has been able to collect through correspondence 103 items of this character, occupying 107 pages of the *Transactions*. The character of the matter may be judged from the following titles of some of the notes: Truing engine pins; feed water heater on a gas engine exhaust; a home-made traveling crane; repairing a defective boiler crown sheet; keeping a commutator in good shape without turning or sand-papering; a coil-winding machine; running 9.6-ampere lamps and 6.6-ampere lamps from the same machine; reducing standby losses during light load; transformer testing set for line use; locating breaks in series arc circuits; water rheostat used as a starting box; a special transformer for thawing frozen water pipes—there being several notes on this subject; a novel electric sign.

The New Officers.

Some little difficulty was experienced in selecting the new president. Mr. J. W. Lieb, Jr., was in direct line, but it was realized that as incoming president of the American Institute of Electrical Engineers, he had already as much as he could well attend to. Among those favorably discussed were Messrs. Arthur Williams, of New York; J. B. McCall, of Philadelphia, and Alexander Dow, of Detroit. The choice finally fell upon Mr. E. H. Davis, of Williamsport, Pa., who filled with conspicuous ability last year the arduous position of secretary. The other officers elected were as follows: First vice-president, W. H. Blood, Seattle, Wash.; second vice-president, Arthur Williams, New York; secretary, Dudley Farrand, Newark, N. J.; executive committee, Samuel Scovil, Cleveland; A. J. De Camp, Philadelphia; W. F. White, St. Louis.

SMOKELESS BOILER SETTING.

BY A. BEMENT.

Even with a chain grate stoker as usually set under a water-tube boiler, there is a considerable amount of smoke produced from bituminous coal, owing to the gases passing among the boiler tubes before complete mixture of the combustibles in the gas and air can be effected. That combustion may be complete there must be a thorough mixture of the gas and air while still hot; for this to be effected requires that some interval of time exist between the distillation of the gas and its cooling to below the combining temperature. Experience has shown when a chain grate stoker is used that a fire brick arch, or its equivalent, of 14 to 16 feet in length maintains temperature for a period long enough to accomplish the purpose.

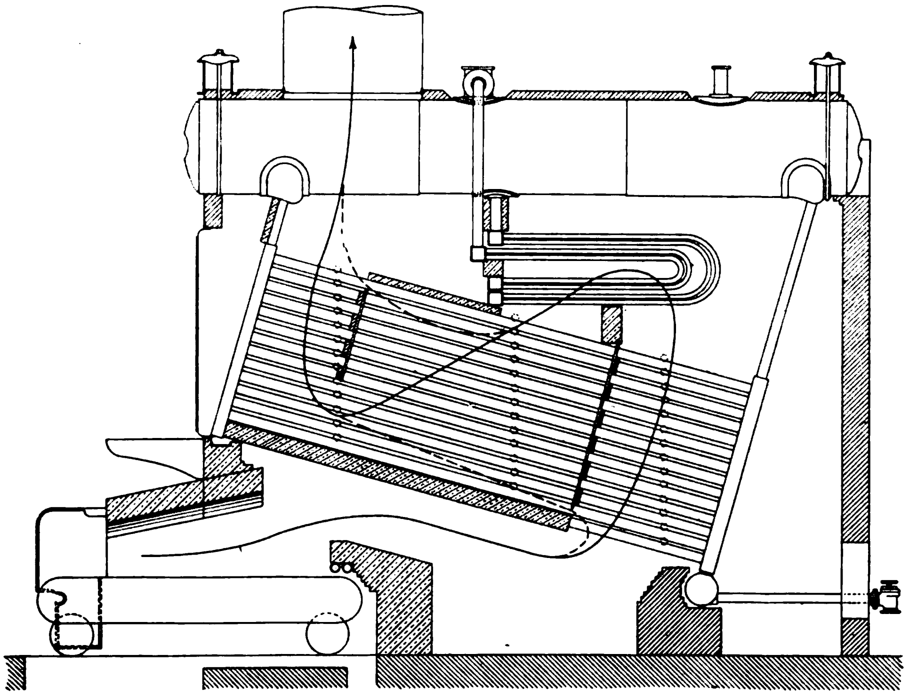

FIG. 1.—BOILER WITH TILE ROOF FURNACE—SHORT GAS TRAVEL.

Some two years ago, the problem of devising a smokeless application of chain grate stokers to Babcock & Wilcox boilers presented itself in an important installation, and it was proposed to suspend tiles from the lower row of tubes as shown in the accompany views, Figs. 1 and 2. This scheme changes the arrangement of the apparatus somewhat. The gases, instead of rising at the front end of the boiler do so at the rear, and in place of leaving at the rear, leave at the front, their path being shown by the arrow. As observed the superheater is reversed in position, but its location is the same as far as exposure to hot gases is concerned. Fig. 1 shows an arrangement of baffles, which allows of the employment in their usual location of the side openings used to blow off the tubes, and Fig. 2 shows an arrangement which causes the gases to flow in contact with a greater amount of boiler surface, which causes an increase in the amount of heat absorbed; as observed, small openings are left at the bottom of the baffles to allow of the exit of dust, also at the top for the purpose of inducing a mild flow of hot gas into what would be dead corners.

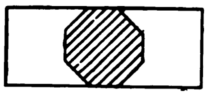

FIG. 3.

Two water-cooled iron pipes are shown under the bridgewall in Fig. 1. Experience has show that this is the best safeguard against careless operators who might feed a serious amount of fire over the end of the grate. The form of bridgewall shown in Fig. 2 is all that is required with a chain grate of proper proportion, provided it is located in a furnace and there is assurance that the fire will not be allowed to feed over the end.

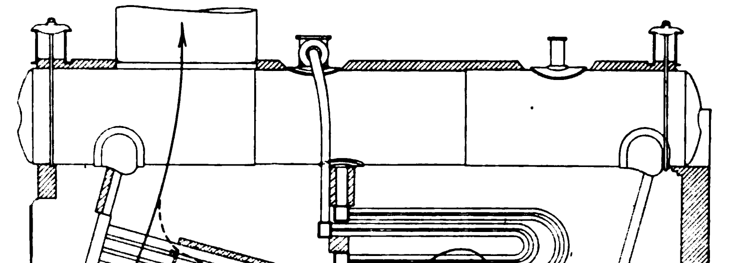

FIG. 2.—BOILER WITH TILE ROOF FURNACE—LONG GAS TRAVEL.

It will be observed that the change in the Babcock & Wilcox setting consists in the application of a furnace, producing a grate, furnace and boiler in place of grate and boiler. The form of tile for the furnace roof which gives best satisfaction is shown in Figs. 3 and 4.

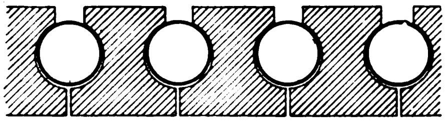

FIG. 4.—SECTION THROUGH TUBES AND TILES.

A THREE-WIRE, 500-VOLT LIGHTING SYSTEM.

BY WALTER I. BARNES.

The first American installation of any magnitude using so-called high-voltage incandescent lamps was made at St. Louis in 1898; owing to certain legal obstructions, however, the St. Louis system was not installed as a pure three-wire arrangement. The first central station to adopt a direct-current, three-wire, high-voltage feeder and main system, with a grounded neutral, was the Narragansett Electric Lighting Company, of Providence, R. I.

The original request of the general manager called for a report on a five-wire system using 125-volt lamps and a three-wire system using 250-volt lamps, and a joint report was presented by Mr. William C. Woodward, the electrical engineer of the Narragansett Electric Lighting Company, and Mr. B. J. Arnold, in May, 1899. The immediate decision of the manager was in favor of the three-wire system. With the 250-volt lamp as a factor in the situation, the alternating-current transformer was no longer a necessary part of the system, for wherever a 500-volt, two-wire system could be operated to advantage, it was possible to modify the arrangement so as to allow of the use of a three-wire, 250-500-volt system.

In 1899 the Narragansett Electric Lighting Company had a connected load of 9000 kilowatts, of which 4900 kilowatts was in alternating-current, multiple distribution, 2700 kilowatts in direct-current, 500-volt motors, 400 kilowatts in commercial series arc lamps, and 1000 kilowatts in series arc lamps on city contracts. The electrical generating equipment consisted of three 500-kw., alternating-current, 60-cycle generators, three 500-kw., direct-current, 500-volt generators, 16 Thomson-Houston series generators of 50 lights capacity each, and 18 Fort Wayne series generators of 125 lights capacity each.

A city ordinance relating to overhead wires required that all overhead construction of the Narragansett Electric Lighting Company within the close fire district of the city should be removed within three years from the passage of the act. This necessitated the removal of 600 poles and about 160 miles of wire in any event, and the company, for the benefit of the service, voluntarily increased the area of territory about 100 per cent.

FIG. 1.—GENERAL CONSTRUCTION OF MANHOLE.

In general, the proposed reconstruction provided for the construction of a complete underground system, an installation of a storage battery, the discontinuance of the alternating-current system in the close fire district and some adjacent territory, the discontinuance of the commercial series generators, and the removal of the poles and wires as required by the ordinance. The construction of the conduit system was begun in October, 1898, and continued until December, 1901, during which time about 40 miles of streets were opened and 1,700,000 feet of ducts were laid. Of this amount about 1,000,000 feet are single-duct and 700,000 multiple-duct. There were built about 850 manholes of an average size of six feet square and seven feet deep. The general construction of the manhole is shown in Fig. 1. The ducts that were used in the underground system were laid on a three-inch bed of concrete, which was spread on a spruce board bottom; the side walls beyond the ducts were of concrete three inches thick and well rammed between the side boarding and the ducts. Over the ducts was a three-inch layer of concrete, above which was placed a protective layer of creosoted plank an inch and a half thick. After laying, the ducts were all rodded and cleaned, ready for drawing in of cable.

Owing to the peculiar location of the streets along the river front, the conduit system was often below tide level, and it became necessary to waterproof the system of conduits and manholes where they were close to the water front. This was accomplished by building 12-inch side walls on the concrete bottom of the trench, and covering the side walls and concrete with several layers of tar paper laid in hot asphalt. The waterproofing of the manholes was accomplished in a similar manner, and the results indicate that such a method is perfectly satisfactory.

Into this system of ducts there was drawn about 2,000,000 feet of cable, varying in size from No. 14 B. & S. gauge, used as potential wires, to cables having an area of 1,000,000 circular mils, used as tie lines between generating and battery stations. Rubber-covered cable only was used, the insulation being Okonite, varying in thickness from 5-32 to 9-32 inch, according to purpose for which it was intended. The thinnest insulation was used in the three-wire system. For the alternating-current, 2200-volt system, and in the constant-current, 6050-volt system, the insulation is 7-32 inch thick, and in the 11,000-volt transmission circuits the thickness of insulation is 9-32 inch. It is worthy of note that in five years of continuous operation not a single fault has developed in the cable or conduit system.

In the direct-current system, the main conductors have an area of 200,000 and 300,000 circular mils, according to the district in which they are situated. The feeders vary in area from 200,000 to 500,000 circular mils, according to length and load. There are 33 feeder points in the direct-current system, and the connected load at present is about 9000 kilowatts, of which 4000 kilowatts consist of stationary motors varying in capacity from 0.25 kilowatt to 75 kilowatts. The remainder of the load consists of 80,300 incandescent lamps and 1280 arc lamps. The incandescent lamps average 3.3 watts per candle-power, and have a useful candle-hour area of not less than 4000 hours, assuming the smashing point to be at 80 per cent of the initial candle-power.

The arc lamps in use at present are of the twin-carbon enclosed-arc type, and operate in multiple on 250-volt circuits—that is, two arcs in a single inner globe—the current averaging 2.3 amperes and the energy per lamp averaging about 575 watts; the two arcs are in series. This lamp has proved quite satisfactory, and is much to be preferred to the single-carbon lamp with about 160 volts at the arc.

For the purpose of producing the best possible regulation and also to tide over the peak load, a storage battery was installed at a sub-station about 2400 feet from the generating station, in a location which in time will be fairly in the centre of the distributing system. The battery consists of 296 cells of 43 plates each, and has an eight-hour discharge rate of 840 amperes. The cells are mounted on an insulating system which has served to obviate the various troubles often found in battery insulation. A double tier of porcelain insulators is used; the first tier is mounted on four brick piers, which are capped with a hard-pressed tile thoroughly impregnated by boiling in paraffin; triple-petticoat porcelain insulators are then placed on the tile. Longitudinally with the cell and resting on the four insulators are placed two hard-pine sticks, four inches by four and three-quarter inches, well painted with an acid-proof paint. On each of these sticks are placed three tiles boiled in paraffin, and resting on these tiles is a second tier of porcelain insulators; these support the battery tanks.

The distance from the floor to the bottom of the tank in 20¾ inches. The floor under each cell is pitched from a point under middle of cell to the aisle between the cells at an angle of about 20 degrees. This allows any surface water or drippings from the tank to drain off rapidly. Frequent washings of the floor immediately under the tanks and systematic cleaning of the insulators that may be conveniently and safely reached. have served to produce the best results in practice, the leakage to earth being entirely eliminated.

The battery is seldom discharged in regular service above the three-hour rate, and then only for a period of about an hour. The load on the system is so nearly balanced that the unbalanced condition seldom exceeds 3 per cent of the load, and the neutral conductor is of ample capacity, even should the unbalancing greatly exceed the figure given. In order, however, that the battery may be always in balance as near as possible, a balancer generator is to be installed.

As the 250-500-volt three-wire system was a radical departure from all standards then existing, every precaution was taken to obtain the best and safest results. It was decided to re-wire most of the older installations, and although in many instances the wiring in customers' premises required but slight modification, yet there were other cases where the entire wiring equipment was replaced.

Certain types of fittings were adopted as standards, so that the installations might be uniform throughout the entire territory. The Edison type of fibre-lined socket with a mica disc under the centre contact was adopted. Enclosed fuses of the plug and cartridge type were used to replace open-link forms. Modern switches took the place of older patterns, and iron or steel pipe was generally used to replace wooden moulding.

There was naturally a great saving in the amount of copper used in the new system. In re-wiring some old installations it was not unusual to find two or perhaps three No. 0000 wires in each side of the mains, run in a heavy moulding from transformer to centre of distribution, the installation having been made in the old days of 4.5-watt, 50-volt lamps. These conditions were in marked contrast to the small iron pipe run from manhole to centre of distribution, containing three No. 10 wires which supplied the same amount of power. Aside from the very material view of the investment saving under the new arrangement, there is the æsthetic viewpoint, which is much better satisfied in the improved construction made possible by the features of the present system.

The several sections of the city that were included in the changes were served with about 50,000 incandescent lamps, 1000 arc lamps and 2000 kilowatts in stationary motors, and these installations were reconstructed to comply with the requiremnts of the new system. The changes from aerial to underground supply, and from alternating-current to direct-current service, were made without any interference with the customers.

The commercial series arc lamps being replaced by multiple arc lamps of the new type, the series generators were released from service at the central station. The arc lamp situation was at first rather perplexing, as none of the larger manufacturers were inclined to provide such a lamp as was demanded. A lamp manufacturer finally produced a lamp that was the forerunner of those now generally used.

All motors of the direct-current type are connected to the outside or 500-volt wires, and although these motors operate devices that are subject to wide and sudden changes in load, the lighting service is not effected by the disturbances of load condition.

In a central station already operating a two-wire 500-volt motor system, the addition of a third wire is all that is necessary to obtain an efficient and a flexible wiring system for lighting purposes. The fact, too, that the same generating apparatus may be used for both motor and lighting service is no small factor in the situation, the natural motor load being a day load, while the lighting load, generally extending well into the night, serves to produce a very satisfactory load curve, particularly if a properly proportioned storage battery forms part of the equipment. The direct-current load curve of the Narragansett Electric Lighting Company is of such a character that during 17 hours out of the 24 a 2000-kw. unit could be operated under advantageous conditions.

The management of the Narragansett Electric Lighting Company, realizing that the public was to be given every consideration in the matter of protection, laid the plan of the proposed system before recognized authorities on fire hazards, and received their approval for the undertaking of the work. The personal risk was also fully discussed, and it was decided that there was no objection to the installation of the system described when accident to person was considered. Vindication of this decision is found in the fact that during five years of operation there has not been a single fire loss or personal injury for which this system was responsible.

The author personally favors the general use of a neutral conductor, which is continuous from source of supply to point of use, and is thoroughly grounded at every possible point inside the customers' premises, and certainly in the network of mains and feeders in the streets. Then the use of single-pole switches on the positive and negative sides of the system is a sufficient means of opening any branch circuit. A typical installation embodying these ideas is the wiring system in the Union Trust Company Building at Providence. In this building the neutral consists of a continuous copper conductor from the street mains to the top floor of the building, which is twelve stories high. At each floor there is a centre of distribution for that floor, these centres being supplied by one of the four-feeder circuits from a main distributing board in the basement—each feeder circuit supplying three floors. All tap circuits are single-wire, the pipe system and frame of building being used as a neutral conductor for the branches. The ends of the pipe system at centres of distribution are bonded together and to the copper neutral riser. Single-pole switches and cartridge fuses are used in the branch circuits.

In connection with this installation it may be noted that the space required for the positive and negative feeders in the wire shaft is only 3 ins. x 9 ins., each feeder being installed in an iron pipe. Comparison of this space with what would be required if a 110-volt system were used, will give some idea of the practical economy in operating at the higher voltage. The installation just cited is but an instance of the use of the intentionally grounded neutral—the whole system being planned on similar lines; in some instances, where it was found advisable, bare copper is used in the neutral branches.

All previous references in this paper have applied to the direct-current system, but the Narragansett Electric Lighting Company has proved to its satisfaction that the same general methods may as well be used on alternating-current systems. The direct-current system having been well established on the lines indicated in this paper, changes are now in progress which in a few months will place all alternating-current service on a three-wire system of 250-500-volt secondary mains with grounded neutral. Several sections of the city outside the direct-current district have already been remodeled with results that confirm the calculations. When the changes shall have been finally accomplished the entire incandescent lamp business of the company, amounting to about 185,000 lamps on a 16-c.p. basis, will be operated at 250 volts, and all motors, both direct-current and alternating-current, will be of standard 500-volt types.

[The foregoing is an abstract of a paper read before the Boston convention of the National Electric Light Association.]

TABLE OF SIZES OF SERVICE LATERALS.

200	300,000 circ. mils. for all laterals up to 75 feet.											

Distances given are from mains to service box.

Wire sizes in B. & S. gauge and circular mils. All conductors larger than No. 6 are stranded. Insulation, Okonite 5/32 in. wall, 1/10 in. lead.

Breakdown strain 10,000 volts alternating current.

Abstracts from Foreign Contemporaries

Humming of Dynamos.—In a recent number of the *Zeitschrift für Elektrotechnik,* J. Fischer-Hinnen deals with the causes and the remedies for the humming of dynamos. This phenomenon appears to a considerable extent only in machines with laminated poles and a small number of slots per pole, six to nine, and increases generally as the air-gap increases. By means of tuning forks of known frequencies, the author determined the note given off by various machines, and it was found that these agreed in every case with the number of armature teeth that passed a given point in a second. The inference was therefore that the sound is produced in the laminated poles by the variation of the flux due to the teeth, and it is evident that the strength of the hum increases with diminishing numbers of teeth per pole. As a result of a number of tests, the author has found that if the equation $\frac{b - 0.7r}{(D + 2\delta)\pi} N =$ a whole number + 0.5 be fulfilled, then humming will not occur at all or only to a small extent. In this equation, b = peripheral width of pole shoe, r = radius of the rounded-off portion of the pole top, D = diameter of armature, δ = air gap, and N = number of slots. Although the above equation was correct with regard to the machines tested, the author does not put it forward as reliable in all cases, since it does not take into account the slot width.

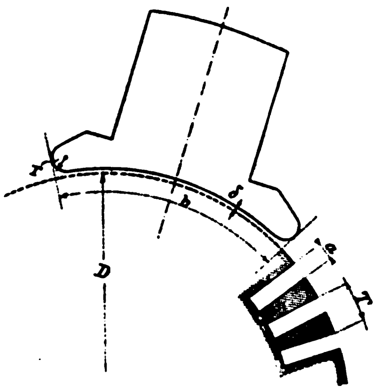

FIG. I.—HUMMING OF DYNAMOS.

Melhuish's Internal-Combustion Engine.—In the operation of the internal-combustion engine of A. G. Melhuish, which is described in the London *Mechanical Engineer,* the suction valves are worked automatically without the use of side or lay-shaft gearing cams, levers, etc., while an arrangement is provided whereby the exhaust gases are completely silenced. The engine, which works on the four-stroke cycle, is shown in Fig. 2. It comprises a duplex piston *A B* of differential areas, the front or larger end *B* being of such diameter as to be a little more than double the area of the smaller or working piston *A*. The differential piston works in the cylinders *C D*, and at a position corresponding to the piston's complete outstroke a port *E* is formed leading into a condenser chamber *F*. This condenser *F* is also in communication with the front or larger cylinder by the port *G*. The inlet air and gas valve *H* is provided to the working cylinder. A valve *I* opening outward is provided to the condenser *F*. The engine works as follows: A charge is compressed and fired. This expands and forces out the pistons, *A B* doing work, at the same time a partial vacuum being created in the condenser *F* and front or larger cylinder *D*. At the completion of the outstroke the pressure remaining in the working cylinder *C* passes through the port *E* into the condenser *F*, the partial vacuum within entirely silencing the noise by reason of its rapid expansion in a void. The second or instroke now commences, and displaces the products from the vacuum cylinder *D* and condenser *F* through the non-return valve *I*, and the products remaining in the working cylinder are compressed. The third or outstroke now commences, the products re-expanding, and a vacuum being again formed in the condenser *F* and large cylinder *D*. As soon as the piston reaches its outstroke limit, the air and gas inlet valve *H* is opened by reason of the vacuum and this vacuum is satisfied by the inrush of a new charge into the working cylinder *C*, the old products being withdrawn into the condenser *F*. The fourth or instroke compresses the new charge and empties the condenser for the cycle to commence again.

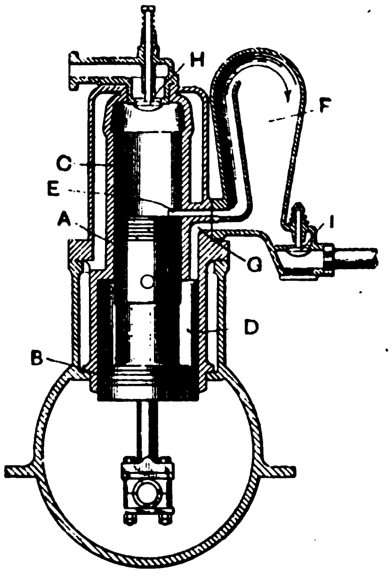

FIG. 2.—MELHUISH INTERNAL-COMBUSTION ENGINE.

Exhaust Valve Control for Gas Engines.—The controlling mechanism for the exhaust or release valves of internal-combustion engines shown by Fig. 3 is described in a recent issue of *The Mechanical Engineer* of London. The mechanism is especially applicable to motors governed by varying the quantity of explosive mixture drawn in by suction. The exhaust valve *A* is operated by two levers *B* and *C,* acting through the intervention of rolling surfaces so as to decrease the power necessary to move the valve from its seat. One of the levers *C* is operated by the rod *D* of an eccentric *E* keyed on the valve gear shaft *F* so that the motion of the valve is invariable with that of the engine piston. The exhaust valve opens with a suitable lead and closes toward the end of the stroke which expels the burned gases. One part only of the stroke of the eccentric *E* is used to operate the valve, the remaining part of the eccentric's stroke being utilized to increase the tension of the valve closing spring *G* during the engine piston's suction stroke which follows the stroke which expels the burned gases. The maximum compression of the exhaust valve spring takes place at about the end of the suction stroke. By this arrangement the exhaust valve *A* is relieved of part of the pressure of the valve closing spring *G* at the moment it begins to rise, the tension of this spring remaining constant the whole of the time the valve is being lifted. It is possible to give the valve spring *G* sufficient tension to prevent the valve being unseated by the action of excessive vacuum in the cylinder.

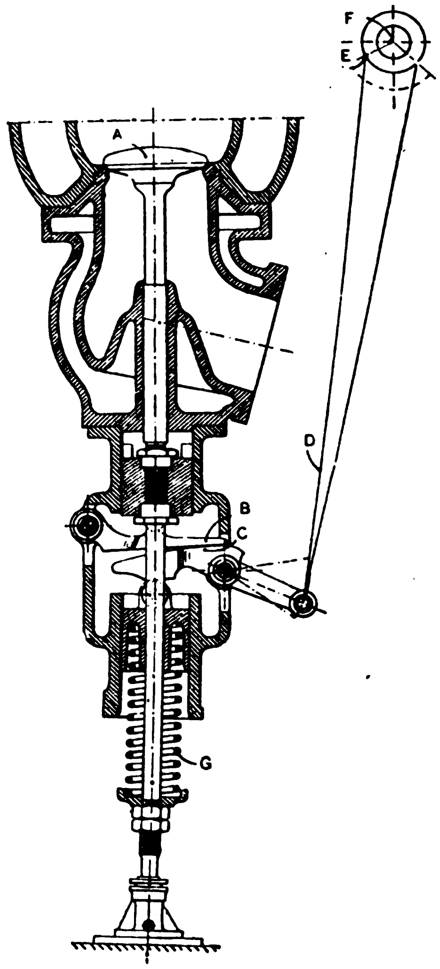

FIG. 3.—EXHAUST VALVE CONTROL OF GAS ENGINES.

Lancashire Reversible Booster.—Two boosters have been included among the recent extensions to the Derby Electric Works and Tramways which are described in a recent issue of the London *Electrician.* One is an ordinary shunt-wound reversible motor-driven booster for charging and discharging the cells on the lighting mains, and can deal normally with a current of 100 amperes, raising the pressure by 70 volts, and will deal with 200 amperes for one hour. The traction booster offers several interesting features, however; it is an automatic reversible booster and provision has been made with considerable ingenuity for almost every possible contingency. It is constructed under the Turnbull and McLeod patents. In external appearance this latter machine is merely a four-pole dynamo driven by a four-pole motor; but, while the motor is nothing more than a shunt motor, the booster itself has four field windings (see Fig. 4). One of these (*A*) is a shunt winding across the booster terminals, excited by the difference of potential between the battery and the bus bars. *B* is an auxiliary shunt winding, which the makers call the "potentiometer shunt," connected straight across the bus bars. *C* is a series coil between the negative dynamo terminal and the negative main, and *D* is a series coil of a few turns in series with the armature of the booster itself. The object of the reversible booster is, of course, to keep the load on the dynamos practically constant, the battery discharging when the load rises above the normal and charging when it becomes less than the normal. Taking into account the large variations in the voltage of a battery (not only with varying current but with the same current at different times), it is evident that the first requisite is an exciting coil which shall always make the sum of the battery and booster voltages practically equal at all times to the bus-bar voltage. This is accomplished by putting on the coil *A*, excited by the difference between the battery and bus-bar voltage. If the booster is worked on the straight part of the characteristic, it will be seen that this coil can be made to give a voltage on the booster armature always equal to the difference between the battery and dynamo voltage; also a very slight increase or decrease in the excitation will cause the battery to charge or discharge. The second shunt coil, *B*, across the bus bars tends to increase the voltage on the booster, which, again, would increase the effect of coil *A* and the battery would charge heavily; as however *B* is opposed by *C*, which is a series coil in the dynamo circuit, the arrangement is stable when the current in *C* is such that its magnetizing effect just balances that of coil *B;* and as *B* is a constant shunt coil, the current in *C* must always be constant, which is what is required. The series turns *D* added in the battery or feeder circuit make up for the armature reaction and drop of the booster itself. If the dynamo tried to take an overload, the coil *C* would overpower *B* and the battery discharge until equilibrium was restored; on the other hand, if the dynamo current tries to reduce on light load, coil *B* overpowers *C* and the battery charges until they are balanced. The makers point out that, as the booster depends for its control on the dynamo current, and not on any balancing of voltage depending on the dynamo characteristic, compound machines can be used as well as shunt, and all trouble from shunting and kindred causes is avoided. Most boosters which do not depend on the falling characteristic of a shunt dynamo rely on the drop in volts on the battery and booster in discharging, which is balanced by a series coil in the feeder; if that coil is not exactly of the right strength, the battery discharges too much or too little, usually varying with the state of the battery. The particularly valuable property of a coil in the dynamo circuit consists in the fact that it can be made as strong as desired and always balanced by a regulator on the shunt coil to fix the dynamo current at anything required, and if the current should vary acts with very great force to bring it back to the normal again, thus making the booster very stable and greatly facilitating paralleling. If it is desired to use the battery and the booster on the line without the generators, coil *A* is disconnected and coil *C* connected to help coil *B*, giving the battery a constant voltage with varying load. The field magnets are laminated throughout, including the yoke, giving the quick reversal so necessary for traction work. The booster is designed for a working current of 200 amperes normal and 300 amperes for 1 hour, and to supply 70 volts for prolonged periods and 120 volts as a maximum. The machine runs normally at 800 r.p.m.

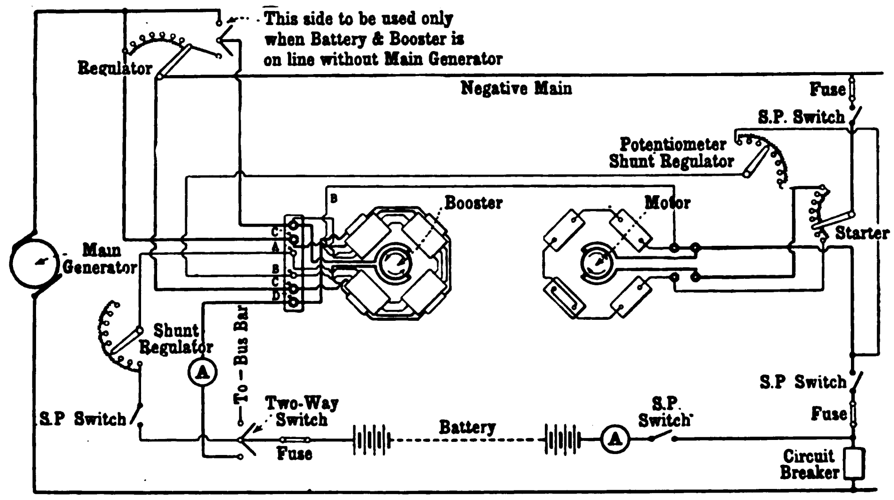

FIG. 4.—DIAGRAM OF CONNECTIONS, LANCASHI RE REVERSIBLE BOOSTER.

Automatic Cut-off Gear for Internal Combustion Engines.—*The Mechanical Engineer* of London describes an automatic cut-off gear for internal-combustion engines by means of which variable impulses are given to suit the load. The gear, which is shown in Figs. 5 and 6, comprises a small cylinder formed inside the casing *A* of the valve *B* which controls the admission of gas and air to the power cylinder of the internal-combustion engine, and inside this small cylinder is fitted a sliding cut-off valve *C* in the form of a sleeve with a piston head. This valve *C* has a series of ports *D*, and the admission valve casing *A* has corresponding ports *E* and *F*, the ports *E* leading from the air supply passage *G* and the ports *F* from the gas supply passage *H*, so that when the ports correspond with each other in position, as shown, and the admission valve *B* is open, there is free passage for gas and air from the supply passages into the power cylinder, but a small endwise movement of the sliding cut-off valve *C* will close, or partially close, the ports *D, E* and *F*, and so cut off admission to the power cylinder. The admission valve *B* is held normally closed by a spring *I*, and the cut-off valve *C* is held normally open by two springs *J*. By the springs *J* the piston head of the cut-off valve *C* is held close up to the end of its cylinder, so as to leave as little clearance

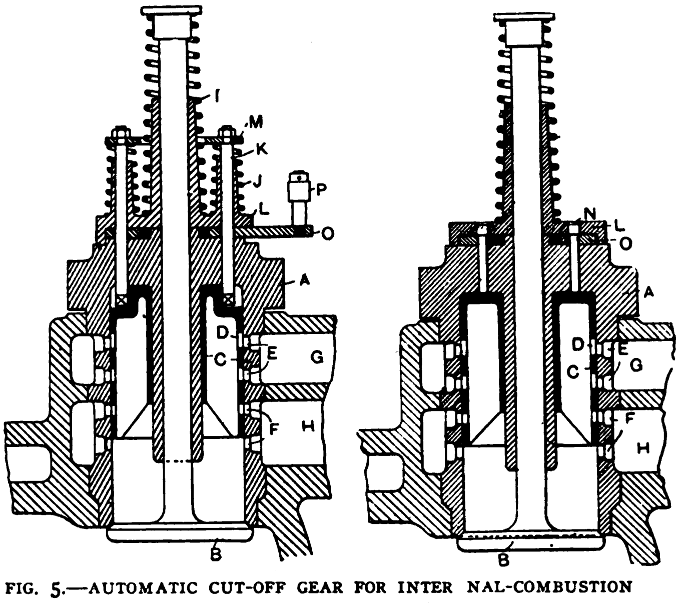

FIG. 5.—AUTOMATIC CUT-OFF GEAR FOR INTER NAL-COMBUSTION ENGINES.—FIG. 6.

space as possible. Communicating with the closed end of the cut-off valve cylinder are a number of small air holes *N* in the cover *L* and casing *A*, and these holes *N* are closed or more or less opened by an oscillating regulating plate *O*. The regulating plate *O*, which oscillates on the admission valve spindle as its centre of movement, has holes in it corresponding to the holes *N*, and it is actuated by a connecting rod *P* connected to the governor. When the governor, by means of the connecting rod *P*, moves the regulating plate *O* so as to close the holes *N*, no air can obtain admission to the end of the small cylinder at the back of the cut-off valve piston head, and therefore, although the suction on the other side of the piston head, due to the movement of the main piston of the engine making a suction stroke, tends to move the piston head with its cut-off valve *C*, it cannot move, being held back by vacuum, and consequently a full working charge of gas and air is drawn through the open ports *D, E* and *F*, into the power cylinder, and full working impulse of the main piston will follow. When, however, the governor moves the regulating plate *O* so as to open the holes *N* to the atmosphere and admit air to the back of the cut-off valve piston head, the suction of the main piston will cause the piston head with its cut-off valve *C* to move during the suction stroke of the main piston, earlier or later, according to the extent to which the holes *N* are opened by the regulating plate *O* as determined by the governor. The earlier or later movement of the cut-off valve *C* will decide the point at which the gas and air admission is cut off during the suction stroke, as well as the volume of charge drawn in and the power developed by the following impulses, which are thus controlled by the governor.

New Single-Phase Motor.— An interesting patent for improvements in single-phase motors granted to Crompton & Co. and R. Goldschmidt has just been published in the London *Electrician*. The inventors claim to have obtained a better starting torque, and without the use of a commutator. The invention is based on the well-known law, in accordance with which a closed coil of conducting material placed in an alternating magnetic field will set itself in such a position as to enclose the smallest possible number of lines of magnetic force. A closed coil, *C* (Fig. 7), suspended, pivoted or mounted on an axle within a two-pole magnetic field, *FF*, excited by an alternating current in the coils, *SS*, so that its plane makes an angle with the direction of the lines of force, will have a current induced in it and a force exerted upon it tending to set it with its plane parallel to the lines of force. When the coil is moved into this position the inductive action ceases and the current in the coil falls to zero. In order to obtain continuous rotation, the circuit of the coil is automatically broken as the plane of the coil lies parallel to the lines of magnetic force, by means of a collector ring consisting of two segments, *PP*, to which the two ends of the coil are connected and which rotate with the coil. In the case of a coil placed in a two-pole magnetic field each segment should subtend an angle of about 90°. Two brushes, *BB*, connected together electrically, either directly through the lead *L*, or through resistances, choking coils or condensers, and placed at opposite ends of a diameter, must be provided and fixed so as to rub on the two segments of the collector ring. These brushes must be so placed, and the exact angle subtended by the segments of the collector ring must be such that the coil *C* will be short-circuited, or partially short-circuited, by the brushes *BB* while passing through any two opposite quadrants of a circle, and will be on open circuit while passing through the other two quadrants. If sufficient momentum is provided in the revolving coil itself, or parts attached to it, to carry it through that part of the revolution in which it is on open circuit, such an apparatus will constitute a simple form of single-phase, alternate-current motor. In order to avoid the disturbing effect of the armature reaction the poles of the field magnet may be split, in the middle, or a short-circuited winding be inserted in them. In order to be independent of momentum for obtaining continuous rotation, and in order to avoid all electrical and mechanical irregularities, the inventors prefer to employ several rotating windings, or coils, instead of one. These coils would be situated equidistant from one another, and the segments of their collector rings and the brushes belonging thereto would be so situated, relatively to one another and to the coils, that the coils become short-circuited or partially short-circuited as soon as they enter under the poles of the magnet, and are open-circuited again as soon as they pass the centre point of the poles of the magnet.

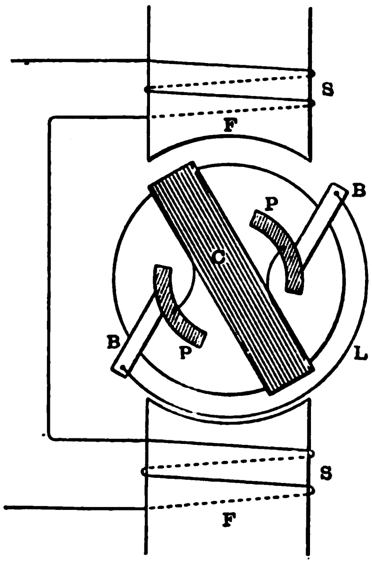

FIG. 7.—SINGLE-PHASE MOTOR.

Automatic Reversible Booster. — In an illustrated description of the Leicester Corporation Electric Tramway published in the London *Electrician* an account is given of an automatic reversible booster which combines many interesting features. One of the main features of this system is the use of the Thury automatic pressure regulator for automatically maintaining a constant load on the generators running in parallel with the battery. The booster armatures are drum-wound, with a slightly channeled core, and the coils are held in by driving horns. A double-wound armature is employed, and each winding is connected to a commutator, one at each end of the machine. The two armature coils can be connected in series or parallel as required. In the design of the reversible booster special attention has been paid to meeting rapid changes of load and voltage without sparking. With these armatures the winding on the smooth core is placed as near as possible to the periphery, and with the tangentially arranged field coil the iron in the field magnets is reduced to a minimum. The combined efficiency of the reversible booster set is 81 per cent. After a six hours' run at full load, the temperature rise does not exceed 70° F. Fig. 8 is a diagram of connections of the Thury system.

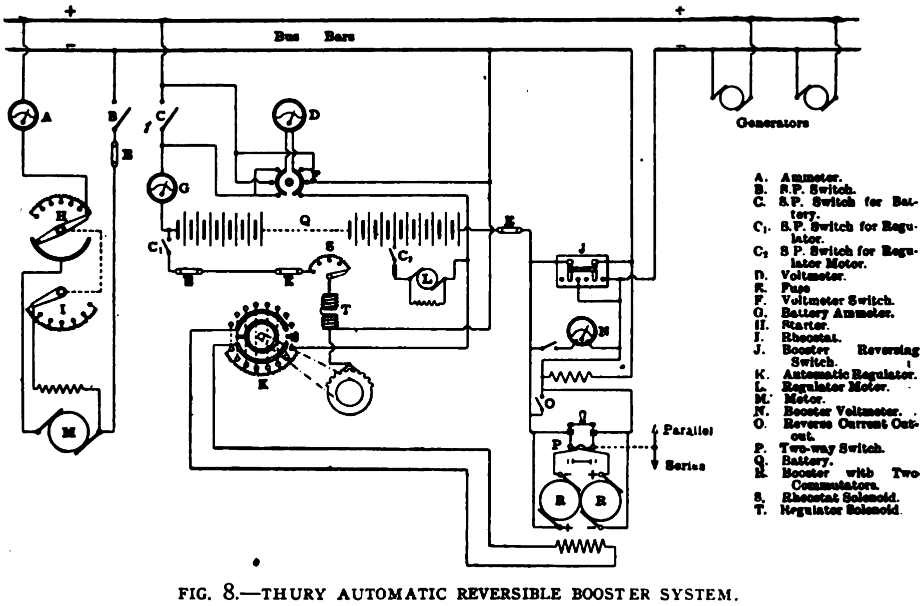

FIG. 8.—THURY AUTOMATIC REVERSIBLE BOOSTER SYSTEM.

The Patent Situation.

To the Editor, American Electrician:

In your June issue I note an editorial (page 293) in which among some wise remarks you make concerning the United States patent system, you also incidentally make some strictures thereon which seem very unfair, and which you ought to be willing to have further discussed. The opening statement that the "patent situation" either excites mirth or disgust, seems to me a little extreme, and the following statement to the effect that the actual value of a patent is usually *nil* until it has been litigated in the courts, is certainly erroneous. Statistics show that something like 90 per cent of the industry of the United States is based upon inventions which are or have been patented. There have been issued something over 760,000 patents, and the courts have from the beginning to this date had before them, for consideration in any way, less than seven thousand patents. It follows, therefore, either that many patents are good without litigation, or else that only 1 per cent of the patents issued have been of any value. That a business can be built up upon a patented invention when the patent "excites ribald mirth" seems absurd; yet the basis of practically the entire industrial property of this country is found in the value of patented inventions. From the lawyer's standpoint it may be remarked that the litigation is not caused by the patent system nor by the conduct of attorneys, but by the refusal of other men to obey the dictates of law and good conscience. As to the rejection of applications it would seem that the opinion of a bureau consisting of the most uniformly well trained body of men in charge of any government business in the world, ought to prevail against that of a possibly ill-advised critic. But if you say in one paragraph that patents are improperly rejected, it seems a trifle inconsistent to say in the following paragraph that "the most serious feature is the ease with which worthless patents may be obtained." At any rate, a patent "issued without justification" is a nullity, and need not restrict anybody who is informed, while the records and all the patents are easily accessible to public scrutiny, just as the courts are open to all who are aggrieved.

The feature of the American patent law system which is most remarkable and most salutory, and which is nevertheless most widely misunderstood, is this; that the government undertakes to protect an inventor in monopolizing what he has created for a limited period, in return for his thereafter freely giving it to the public, and meanwhile the temporary monopoly can neither accrue to the benefit of the inventor nor in any wise deprive the public of anything unless the invention proves to be a thing of value to the public. That is to say, if the public wants to use the invention, it is proof that the invention is valuable to the public; whereas if the invention is not valuable, the inventor gets no benefit whatever from his monopoly. Or, if a slang phrase may be excused, the system is such that the public pays nothing and the inventor gets nothing unless the inventor first delivers the goods.

The meat in the cocoanut is contained in the editor's sensible recommendation that inventors should at last awake to a consciousness of the fact that a patent is a charter of the inventor's rights and the drawing up of the charter should be entrusted to trustworthy people. If it is true that the liberality of the Patent Office admits of unscrupulous attorneys preying upon the credulous inventor, then, since the Patent Office evidently cannot make distinctions between attorneys, it follows that either the office would have to amend its policy to the detriment of all inventors, or else the public must itself undertake the duty of suppressing unreliable attorneys.

Pittsburg, Pa. F. W. H. CLAY.

[We are always willing and glad to have our statements discussed fairly. General statistics, however, prove very little, and an array of them is seldom the equivalent of argument. The fact that the courts have had to pass upon less than 7000 out of a total of 760,000 patents merely indicates, in our opinion, that most of the patents issued were not worth litigation. We think a contemplation of the Patent Office Gazette will support this hypothesis admirably. However, we explicitly modified our statement as to the value of a patent to apply to "at least the large majority of electrical patents." We will be very glad for Mr. Clay, or any other reader, to mention a few electrical patents on which industries have been built up without any patent litigation.

We had no intention to criticise the Patent Office examiners; the inconsistent results referred to are not due to their inability, but to conflicting court decisions which make life a burden to the examiners.

It is the absolute failure of the government to do just what Mr. Clay admits that it undertakes to do that makes the patent situation what it is. Merely giving a patentee the right to prove the status of his patent in court (if he has enough money) falls far short of "protecting an inventor in monopolizing what he has created, for a limited time." If a single tribunal were established at Washington for passing upon the status of patents and establishing consistent precedents, and if infringers were prosecuted (conscientiously) by the government, the patent situation would speedily change for the better. We are perfectly well aware, however, that governmental prosecution of patent infringers is wildly impractical.—EDITOR.]

THE STEAM TURBINE SITUATION.

To the Editor American Electrician:

SIR:—The article entitled "The Steam Turbine Situation," by A. M. Earl, which appeared in your May number, is interesting, although the author manifests a neatly veiled prejudice against the turbine. In asking the privilege of your columns for reply, I realize the futility of mere expression of opinion unsupported by facts; but I believe that Mr. Earl's article tends to create an unfavorable opinion regarding the turbine which it does not deserve. At the risk, therefore, of inciting an argument, I have undertaken to reply at some length upon the more important points brought out.

Mr. Earl has evidently failed to grasp the full significance of the present status of the steam turbine with reference to its principal competitor. I agree with him that "the reciprocating engine has secured its present prominence by sheer force of merit," and its present state of perfection cannot be overlooked. But has not the turbine also reached its present state by force of merit against overwhelming opposition? The reciprocating engine has had a practically clear field from the start; the turbine, on the other hand, entered this field at a time when the engine was as nearly a perfect mechanism as human ingenuity could make it. The engine has practically reached its limit of development; that of the turbine has but just begun. That the former is true is evident from the fact that within recent years the trend of improvement has been entirely along the lines of details in mechanism and construction, rendered necessary by the immense increase in engine capacities.

Mr. Earl states that reciprocating engine practice is returning to its former conservative condition regarding superheat, speed, stage expansions, regulation, etc. This is true, and for the simple reason that these refinements have been found valueless or else they have been productive of slightly higher economy at the expense of some other function. The turbine is, in a measure, controlled by conditions similar to those of the steam engine, although by no means to as great a degree. It embodies the same thermodynamic problem. But its designers have or should have profited by engine builders' experience so that turbine development should be less erratic and founded on less illusive principles.

Any engineer of close observation will, I believe, take issue with Mr. Earl on his statement that "the steam consumption of the turbine is a disappointment," even though compared to the best modern types of steam engines. In order to form a thoroughly unprejudiced opinion of comparative efficiency, it is not sufficient to compare the results from a few tests made under special conditions, calculated to show up the prime mover at its best. These conditions are of scientific interest, but do not tell the average power plant manager what he desires to know; that is, what results he can obtain under the ordinary or poor conditions of his plant. Engine tests are somewhat like good deeds: the best ones are widely heralded, while the ordinary ones, constituting by far the majority, are rarely placed before the public.

On the other hand, there is no lack of data regarding the performance of successful types of steam turbines under every conceivable condition of service. In the accompanying table are given test data most of which have been furnished from the Westinghouse Machine Company's records of certified tests.

These tests reveal the fact that, if operating conditions are provided commensurate with those of the engine, the steam turbine can meet the engine under its best condition. This occurs because the turbine is better able to take advantage of such conditions than the engine. But it is under the moderate working conditions which characterize the average power plant that the turbine excels, and in fact this is its most promising field. European engine builders have striven for economy to the last degree by carrying pressures up to 250 pounds and superheat up to 400° F. Under favorable conditions, a water rate of about 9 pounds per indicated horse-power-hour has been obtained. With normal pressures, vacua, and no superheat, this rate would be more nearly 13 or 14 pounds per indicated horse-power-hour for good engines; equivalent to 17½ to 19 pounds per electrical horse-power-hour.

TESTS OF STEAM TURBINES UNDER VARYING CONDITIONS.

*Estimated from the assumption of 85% combined efficiency of turbine and generator.

*Estimated from the assumption of 92.5% combined efficiency of turbine alone.

In regard to the statement that "recent tests indicate the probable limit of superheat (of the turbine) not far above the economical limit for the engine," Mr. Earl evidently has the Curtis, Rateau and other forms of multi-cellular turbines in mind. He gives as his reason that "the temperature in the turbine involves larger clearances with decreased economy." He has signally failed in his observations of the Parsons or parallel-flow type of turbine. Axial clearances between moving and stationary blades as high as one inch are employed; not, however, for the purpose of avoiding collision due to differential expansion of rotor and stator, such as occurs in multi-cellular turbines. In the Parsons type, the entire circumference between rotor and stator is occupied by working steam so that an increase in axial clearance does not result in distortion of the velocity diagram by the spreading of the jet during its progress through the various rows of blades in each stage or to the entrainment of the outside steam in the stage chamber. These effects do occur in some turbines of the cellular type and seem to prescribe a smaller running clearance than that desirable for mechanical safety.

Superheat in engines of high expansion ratios is mainly beneficial in reducing cylinder condensation. The advantage to be gained is somewhere near in proportion to the number of expansions. In turbines, cylinder condensation does not have to be dealt with and it is therefore found that, although higher economy may be obtained with higher degrees of superheat, a moderate degree is perhaps more desirable. It is easier to provide for and does not impose such extreme difficulties of maintenance in power station work. The expansion in the turbine is practically adiabatic. If working between 150 pounds pressure and 28 inches vacuum, approximately 23 per cent of moisture would be present in the exhaust. This introduces the element of fluid friction. In turbines employing high surface speeds and correspondingly high steam velocities, it becomes serious. By employing superheat, the point of adiabatic condensation may be deferred to the lower stages of the turbine, and in this manner the fluid friction may be decreased. In the Parsons type of turbine, where low steam velocities are employed, fluid friction is not so important, so that excellent economies are obtained with saturated steam as shown in the table. I know of one turbine plant which operated through cold weather with steam at 100 pounds pressure received through about 250 feet of piping, one-third of which was exposed uncovered to the elements. It was found necessary to install a special pump to keep the exhaust line free from water due to the enormous condensation, but the turbines sustained their load notwithstanding, and at far greater economy than the steam engines which they supplanted.

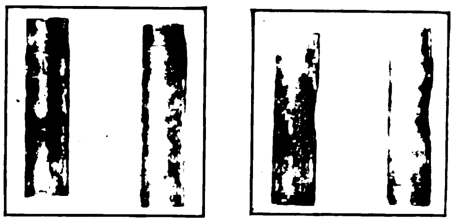
Mr. Earl's statement that "a vacuum of 29 inches is not hard to obtain when the apparatus is new and everything tuned up to 'concert pitch'" requires modification. The vacuum depends largely upon the barometric pressure and the temperature of cooling water. At sea level, a vacuum would be possible that would be out of the question at high altitudes. One station on the Atlantic coast operates the year round on vacuum ranging from 28 to 30 inches and without difficulty, excessive expenditure of power, or extreme care in maintaining the condensing system. At least 25 inland plants are operating on 27-in. and 28-in. vacuum without difficulty; 28 inches may be considered the practical limit with ordinary temperatures of cooling water. The maintenance of this vacuum simply requires good, intelligent work on the part of plant employes. Neither turbine nor engine should be placed in charge of ignorant, untrained labor if good results and high station economies are expected.

Mr. Earl has, I believe, over-estimated the importance of turbine troubles. It is freely admitted by the manufacturers that they have had troubles. Every fully developed machine represents the gradual elimination of defects arising in its predecessors. It is, therefore, hardly logical to condemn a machine on account of real or fancied difficulties simply because these have arisen and have been eliminated. Mr. Earl may have some particular type of turbine in view when he speaks of blades stripping and bearings cutting, mechanical unbalancing, etc. If he had closely investigated the reports from Parsons plants abroad and Westinghouse-Parsons plants in this country, I doubt if he would feel justified in his contention. The troubles which have arisen in the latter have not been kept from those who were legitimately interested; and it is a matter of record that with forty odd units in operation, less than 1 per cent of the blading has shown any indication of trouble from any source. Even this was in no manner due to faulty turbine design, but to distortion of casings by expanding exhaust pipes, and the like.

In no case have the bearings of a Parsons-type turbine been known to heat and cut. This form of turbine is designed with sufficient bearing area to support the weight of the rotating parts without the use of oil under pressure, and the oil is constantly circulated by the turbine itself so that it is impossible for the oil supply to be shut off while the turbine is running. At the least, it can be said upon this point that steam engines also have their troubles; cylinders and valves cut, governors get out of order even to the extent of bursting the flywheel and finally wrecking the engine. All well ordered plants have hose available for submerging hot engine bearings, "mechanical unbalancing creates disturbances" to the extent of requiring massive foundations and holding-down bolts not required for the turbine, wearing parts have to be frequently adjusted, and so on down the list.

The wearing of blades from erosion of steam is frequently advanced as an argument against the turbine. To be sure everything depends on the design, but experience shows that in general the wear does not represent an excessive rate of depreciation on the turbine as a mechanism. Erosion, as in hydraulic work, is practically proportional to the fluid velocities employed, and is aggravated at high velocities by entrained moisture in the steam in the same manner as sand or silt effects a high head Pelton water-wheel. In the simple impulse steam turbine, blade surface velocities as high as 2500 feet per second are encountered, and in some forms of compounded impulse turbines these velocities may be reduced as low as 1500 feet per second. In the Parsons form, however, it has been fortunately possible to reduce the steam velocities to a much lower point—about one-quarter of those occurring in the nozzle type of turbine—with the result that this erosive action is reduced to such a degree as to become entirely negligible.

The difference is strikingly shown in the accompanying illustrations representing the results of experiments under the conditions named. This erosive action may be somewhat reduced in the various impulse types of turbines by evaporating the moisture; which appears to be one of the reasons for the almost universal provision of high superheat in these types. In the several Westinghouse-Parsons plants which have come under my observation, no machines have shown the slightest erosion from steam, even with such abnormally wet steam as noted above.



FIGS. 1 AND 2.—SHOWING EROSION OF BLADES WITH A STEAM JET VELOCITY OF 600 FT. AND 2900 FT. PER SECOND RESPECTIVELY.

It is hardly necessary to point out that "the impressive list of practical qualifications" which Mr. Earl presents in favor of the engine, has been, with two exceptions, entirely met by the turbine. The exceptions are (1) extremely low speeds and (2) belted operation. Both are characteristics of passing engineering practice rather than present. The turbine in general meets the engine upon its own ground in every desirable particular, even to the economical use of exhaust steam at atmospheric pressure. Prof. Rateau has done notable work in this direction.

I agree with Mr. Earl that "the probable outcome of the situation will be a gradual specialization brought about by the test of experience." Considerable experience, however, has already been acquired which has apparently been overlooked in his article. The present position of the turbine is professedly one of specialization with no pretensions to the contrary. The generation of large powers for electric supply and industrial systems and for marine work is at present its admitted field; predictions regarding the future development of the turbine can hardly be made at this time with any degree of certitude.

JOHN R. BENSON.

Boston, June 4, 1904.

NOTES.

A Correction.—In our Exposition article last month it was stated, near the bottom of the second column, page 276, that a Commercial dynamo of 30 kilowatts output, direct driven by a gas engine, furnished power for the other working exhibits in the same space. This was an error; the three-bearing dynamo for gas engine drive is exhibited alone and not in operation.

The International Electrical Congress.—The membership of the International Electrical Congress to be held at the St. Louis Exposition, September 12 to 17, now numbers more than 1000, and more than 700 engineers have signified their intention of becoming members. More than 160 specially requested papers have been promised, a considerable number of which have already been delivered. Communications concerning the Congress should be addressed to Dr. A. E. Kennelly, Harvard University, Cambridge, Mass., who is the general secretary.

National Electrical Contractors' Convention On account of the exceedingly low rates issued by the several passenger associations between St. Louis and other points it has been unnecessary to secure a special rate on the certificate plan for the benefit of delegates and visitors to the National Electrical Contractors' Association, to be held at St. Louis, September 14, 15 and 16. A special convention train will leave the Grand Central Station, New York, on Saturday afternoon, September 10, at one o'clock, for St. Louis, where it is due to arrive on Sunday, September 11, at 6.45 p. m. Special provision is being made for the comfort of ladies traveling on this train. The headquarters for the Eastern delegates will be in the Washington Hotel, Washington Avenue and King's Highway Boulevard. Full information may be obtained from Mr. Alexander Henderson, 527 West Thirty-fourth Street, New York.

More Newspaper Science.—Two of our readers have favored us with the subjoined effusions clipped from daily newspapers which, although widely separated geographically, are evidently bound together by the tie of erudition. Concerning the proposed electrical equipment of the cog railway up Pike's Peak, one of them says:

> "The poles which will carry the wires will each have at the top a lightning rod designed to attract electricity which plays around the Peak so fiercely. The theory is that the poles will catch the 'juice' and transmit it through the rails of the cog road to the power house in Manitou, where it will be transformed and stored for use. They will take the electricity off the Peak and transmit to Manitou, where it can be used for driving trains up and down."

The other, after describing in flowery style the inauguration of a new electric power station, adds:

> "Of the manufacture of electricity it may be briefly said that the dynamo wheel whirls within a vertical circle of radiating soft iron wires. The wheel's surface is covered with many horseshoes of soft iron connected with the 'inciters' which send a current of electricity to them and thus form them into magnets. These magnets whirled before looped wires, charge them with electricity."

Which is not so very bad, after all.

Electric Hauling on Canals.—The results of the hauling experiments made by the Teltow Canal Building Commission, Germany, have just been made public. The locomotive used was designed by the Siemens-Schuckert Works; it has a front truck, both axles of which are driven by an 8-h.p. motor through double spur gearing. There is at the back a free guiding axle. On the truck there is a hauling pole 2.5 m. in length rotating around a horizontal shaft located above the driving axle and supporting at its upper end a funnel through which the hauling rope is slipped. The pole is moved by a 1-h.p. motor, through spur wheel and worm wheel gears. The hauling rope is wound on a drum, which is operated by a 2½-h.p. motor by means of a worm gear. In order to avoid any excessive strains on the locomotive, this drum is not made rigid with its shaft but connected to it through a friction coupling which is disengaged when the pull on the rope reaches 1150 kg. The weight of the locomotive is about 6.5 tons. As shown by the experiments, the pull on the rope is about 0.85 kgr. per ton of effective load, or 0.6 kgr. for a displacement of 1 ton, with a speed of 4 km. The output of the locomotive is 0.0127 horse-power per ton of efficient load or 0.010 horse-power per ton of displacement. Figures corresponding to speeds of 4.5 km. and 5 km. respectively were also ascertained, it being shown that 4 km. is the most economical speed, the consumption of energy at lower speeds being only a little smaller, while with higher speeds a relatively rapid increase is noted. The efficiency of the locomotive when hauling 600 or 1100 tons of efficient load is about 65 per cent.

The Steam Turbine in Germany.—The Siemens-Schuckert Works some time ago entered into a combination with some important firms; including Friedrich Krupp, The North German Lloyd and the Vereinigte Maschinenfabrik Augsburg & Maschinenbau Ges. Nürnberg, for the object of exploiting the Zoelly steam turbine built by the Swiss firm of Escher, Wyss & Co., Zurich. An improved type of this turbine is just being brought out. This is a multiple stage, axial flow turbine, in which the steam is conveyed to the running wheels through guiding wheels so as to have in the high pressure stage a partial and in the low pressure stage a full charge. The guiding wheels are fitted steam tight into the turbine casing, one running wheel being arranged between each pair of guiding wheels. The running wheels are mounted on a common shaft, traversing the whole length of the turbine. On the rims of the wheels are mounted the buckets, which have the form of relatively long rays, their cross section increasing at a regular ratio from the outside inward toward the axle of the wheel, thus maintaining constant the specific strain throughout the length of the bucket. The peculiar construction of the buckets will permit comparatively high wheel diameters and, accordingly, great peripheral speeds to be adopted, thus allowing of a relatively small number of stages.

A turbine direct coupled to a rotary current generator built by the Siemens-Schuckert Works is being operated in the workshops of the company, giving an output of 600 e.h.p. Recent tests made on this turbine by Prof. A. Stodala gave the following results:

KILOGRAMS OF STEAM PER KILOWATT-HOUR.

Saturated steam:	Kg.
At no load without excitation, 205.4 kg. t'tl.	
At no load with excitation, 465.4 kg. t'tl.	
80.1-kw. output	15.0
182.2-kw. output	11.7
240.1-kw. output	10.9
334.5-kw. output	10.1
387.6-kw. output	9.74
II. Superheated steam:	
390.4-kw. output 220° superheat	8.98
391.7-kw output 240° superheat	8.63

The Electric Light Convention.

The Boston convention of the National Electric Light Association was an extremely satisfactory one from every standpoint, so far as an "outsider" is able to judge. The attendance was large, the interest well sustained and the papers rather above the average in quality. There were the inevitable exploitation papers which everybody listens to with more or less resignation, but the ratio of these to the whole was very small. The exhibits were noticeably diminished as compared with previous years, which is easy to explain. This association has for several years been steadily approaching the status of a strictly technical body so far as attention to the regular proceedings is concerned; there is far less of rollicking and indulgence in what might be termed incidental pastime than ever before, and much more earnest attention to the papers and discussions.

It is doubtful if 10 per cent of the delegates to the Boston convention manifested any interest in exhibits which did not include some actually novel features; it appeared to be a "strictly business" gathering. Of course, this has its disadvantages for the progressive manufacturers who went to the expense of making exhibits, but it is a very natural development. The central station business has long since narrowed down to a business proposition requiring for its success the highest order of administrative ability, so that the delegates to these conventions have first and foremost in mind the necessity for exchanging experiences and views and gleaning any information that will assist in promoting the success of their establishments; information regarding apparatus and appliances is obtainable at any time with the utmost facility and minimum effort on their part. Consequently, the interest in the meetings is steadily growing and that in the exhibits is decreasing.

◆◆◆

The Steam Turbine and the Gas Engine.

The papers on these subjects which were read at the convention were mostly disappointing, but the discussions were somewhat instructive. As we remember them now, these papers contained very little that had not been said from once to half a dozen times before, and nothing at all conclusive. Just why any author of a paper to be read before a body of this sort should imagine that those present will be interested in a detailed description of machinery or apparatus which has been copiously described in the technical press long before, is a question to which we have never succeeded in formulating an answer entirely flattering to the author. With this class of material eliminated from the papers mentioned, much time could have been saved and the remainder of the material would have been more effective.

The merits of the steam turbine, as well as its demerits, in its present stage of development are too well known to require enumeration, and we would not presume to venture anything like a prediction as to the future. So fas as one may judge from what has already been accomplished, however, it is reasonable to believe that the internal-combustion engine has far greater possibilities of future development than any other form of prime mover now known. The serious obstacles in the path of gas engine development are the producer problem and the valve-gear, principally the former; this has only begun to receive serious attention in this country, however, so that it is too early to feel discouraged about it. The valve-gear problem is not nearly so serious, but it is an extremely knotty one. That the gas engine valves and gear will eventually be reduced to smoothness and reliability of operation equal if not superior to those of a releasing-gear steam engine cannot be safely questioned, however, and if American engineers *should* fail to bring the producer up to the desired degree of commercial efficiency, it is highly probable that the oil engine will receive the attention which it deserves, but has never had, always excepting the praiseworthy efforts of Herr Diesel.

◆◆◆

The Double-Voltage Arc Lamp.

The arrangement of two pairs of carbons connected in series in a single arc lamp and burning simultaneously dates back almost to the beginning of the art. In our callow youth we "invented" such a lamp, only to discover that we had been saved the trouble several years previously. But there was no real need for such a lamp in those days of simple series circuits. Now, however, the extended use of arc lamps on constant-potential circuits, combined with the steady rising of constant-potential standard voltages, bids fair to change this considerably. A double-voltage lamp is being used in Providence, R. I., on 250-volt circuits and in large numbers, and there is no reason why this type should not prove immensely useful on circuits of lower potential. The enclosed arc works best at 70 to 80 volts potential difference, but it does very nicely with 60 to 65 volts;

circuits of 110 volts nominal are usually operated at from 115 to 125 volts, and there is no objection whatever to running them up to 130 volts, except that 130-volt incandescent lamps are not regarded as "standard." At this voltage a differential double-voltage lamp will operate very satisfactorily. If the standard voltages were raised to 165, 330 and 660, as suggested in another paragraph, double-voltage arc lamps would fit in beautifully, the limit of economical distribution area would be increased approximately 300 per cent and wiring installations would not require logs of copper in the heavy duty lines.

◆

Armature Windings.

As we intimated briefly in a previous number, the grasp of the principle of armature winding is immensely facilitated by considering the winding on the basis of coils instead of conductors. The only argument against this method is that in large armatures a "coil" is not a coil at all, but a loop. This has no more practical bearing than would the argument that the divisions of a commutator should not be called segments because they are not segments in the common geometrical sense. At any rate, if one's ideas of definition are too rudely violated by calling a loop a coil, there is the alternative of calling it by its right name, "loop." The fact remains, regardless of these semi-quibbles, that the practical armature winder not only does not need to know anything about front and back armature pitches, re-entrancy and the rest of the academic terms that delight the heart of the text-book writer, but is merely confused and hampered by them. And while students and designers may be able to get at fundamental principles by way of these devious methods, it is vastly easier to do so without them.

There are two generic types of winding: lap and wave, when reduced to one turn per coil or pair of inductors (in a drum winding). The former have been appropriately termed "multiple" windings, but a wave winding can also be a multiple winding. Either "lap-connected and wave-connected" or "lap-lead and wave-lead" would be more distinctive and descriptive; "equipotential" would fit the wave or wave-lead winding, but it is a clumsy word and there is no antonym, even if a lap winding were inherently non-equipotential. However, no matter what one chooses to call the two types, the only features necessary for one to know are the number of coils and the method of connecting coil terminals to the commutator. The pitch at the armature core has no effect whatever upon the type of winding so long as the two features mentioned are correct; the spread of a coil on the core affects commutation chiefly and the generated e.m.f. to a slight extent, assuming that the spread is somewhere near the pole pitch. The simple wave or wave-lead winding may have any even number of paths up to the number of field magnet poles, while the lap or lap-lead winding necessarily has a number of paths equal to the number of magnet poles, unless it is a duplex or triplex winding. Each set of coils forming one path in a wave-lead winding is subjected to the inductive influence of every magnet pole on the machine simultaneously, so that the e.m.f. is exactly the same in every path; each set of coils in a lap-lead winding, on the contrary, is under the influence of only two magnet poles at any given instant, so that if there should be any difference between the strengths of field under the different pole-faces, different e.m.fs. will be induced in the different paths and cross-currents will flow backward through the paths generating the weaker e.m.fs., overheating the armature dangerously. These are the fundamental characteristics of the two types of winding.

◆

A 500-Volt, Three-Wire, Direct-Current System.

The paper on this subject, which we print elsewhere in this number, will undoubtedly be read with keen interest by central station managers who did not hear it read at the convention. The author describes a very bold policy which appears to have been vindicated by actual application for a period of about three years. For several years we have steadily advocated raising the standard constant potentials to something like 150, 300 and 600 volts, but Mr. Barnes and his associates in Providence have gone 66 per cent beyond our modest suggestion at one leap. Admirable as their progressive daring and intelligent execution are, we are unable to believe that the plan they have adopted is advisable; 500 volts is a very high potential to introduce in people's houses, to begin with, and 250-volt incandescent lamps do not appeal to our ideas of economy. There are, it seems to us, many more but less important reasons why 300 or 330 volts would be a better over-all voltage for a three-wire system than 500, but those just mentioned would be ample to deter us from assuming the responsibility of a 500-volt system. There is no doubt, however, that the present so-called "standard" voltages of 110, 220 and 500 are out of date; there is also no doubt, at least in our mind, that the two higher direct-current voltages should be multiples of the lowest one, whatever that one may be.

The use of the structure of a steel frame building as the neutral conductor for all branch circuits also appears to be unnecessarily radical. The neutral of the system should, of course, be securely "grounded," but dependence upon the frame of a building for one side of a work circuit does not impress us as sound engineering practice. It has a great advantage in simplifying branch circuits and switches, but cases have been known where great simplicity has proved more expensive in the long run than a more complex arrangement.

◆

Electric Heating.

One of the most reasonable utterances from a manufacturer concerning his own class of apparatus that have come within our knowledge recently was the paper on this subject that was read at the Electric Light Convention by Mr. James I. Ayer. The author made no effort to persuade the central station fraternity that electric heating is a commercial proposition regardless of conditions, which is, unfortunately, the attitude that manufacturers are apt to take regarding their own lines of apparatus. His paper very clearly points out the limitations of electricity as applied to heating, but it also contains some valuable suggestions as to the conditions under which electric heating can be made profitable. Making allowance for just a wee bit of entirely human bias, the paper may be regarded as a very safe guide regarding this class of central station service.

There is no reason to doubt that if central stations could afford to put out electric heating apparatus on the same basis as arc lamps, a very considerable addition to the station load could be worked up for the warm and hot months of the year, and possibly for the milder months of May and October in southern latitudes. It is a question, of course, whether or not it would pay to put out apparatus and maintain it free in order to get a relatively moderate increase in load, at reduced rates, during four months of the year; in the abstract it seems a little dubious, but it is a matter to be figured out according to individual operating conditions, of course. There is no doubt whatever, though, that a heating load will be profitable during the "short load" months, at the reduced rates necessary to obtain it, if the customer can be persuaded to buy or rent his apparatus.

DESIGN FOR A LIGHT GASOLINE MOTOR CAR.

BY J. C. BROCKSMITH, M. E.

The accompanying working drawings illustrate a type of gasoline automobile which is about as light and simple in construction as such a machine can be made consistent with good results and still be within the reach of the amateur builder and automobile enthusiast. The well-known arrangement of "motor in front, sliding gear transmission, and bevel gear drive" has been adopted as representing the best practice for light cars. Fig. 1 is a side elevation of the complete machine, which shows the general arrangement and appearance of the car.

The motor is a two-cylinder vertical machine of the two-stroke-cycle type; it is air cooled and located under a well ventilated bonnet in front. The motor has an output of 6 horse-power at the normal speed of 750 r.p.m. The power is transmitted through a cone clutch in the fly-wheel to the transmission gear which provides forward speeds of 6, 12 and 25 miles an hour and one reverse speed of 6 miles an hour, all at the normal motor speed of 750 r.p.m. It will be understood, however, that any intermediate speed can be obtained by the usual methods of shifting the spark and throttle control. The rear axle is driven through a universal joint and bevel gear, the latter being enclosed in the same case which contains the differential gear.

Steering is effected by means of a hand-wheel operating a screw and nut and is of the "irreversible" type; that is, no inequalities in the road can work back through the steering linkage and produce a motion of the hand-wheel. Upon the steering column are also mounted the spark and throttle levers, by means of which the speed of the motor is controlled. The machine is further controlled by means of the clutch release and brake pedals which are seen protruding above the inclined footboard. The gear is changed by means of the lever shown alongside the seat on the right-hand side. When changing from one gear to the next, the clutch pedal must, of course, first be depressed, thus disengaging the motor from the transmission, so that no power is passing through the gears and they can be brought into mesh without danger of stripping the teeth.

The brake acts on the secondary shaft of the change gear, and being geared up to the rear axle in the ratio of 4 to 1 a very powerful braking effect is obtained with a moderate size of brake drum and a comparatively light pressure by the brake.

The gasoline tank is located directly under the seat and is filled through the cap shown in the top, which can be readily got at by removing the seat cushion.

The wood work of the seat is of the simplest possible description, only straight boards being used; the curved surfaces usually seen on automobile bodies would probably be out of the question for anyone who wished to construct the wood work himself.

The body is hung on three springs, a semi-elliptic spring being used in front while the rear springs are full elliptic. The wheels are 28 inches in diameter, have wooden spokes and are equipped with 3-in. detachable pneumatic tires. Fig. 3 is an end elevation of the complete machine which brings out a number of dimensions and points of construction not clearly indicated in Figs. 1 and 2. The front spring is a 38-in. 5-leaf semi-elliptic spring fastened at its extremities to a pair of short links to allow for extension, and at the center is bolted to a wooden cross-bar which is shaped to fit the curvature of the spring and which supports the frame and body of the vehicle. The front axle is given a drop of 1¼ inches below the center line of the wheels in order to give additional room for deflection of the springs and thus prevent the motor shaft from striking the axle.

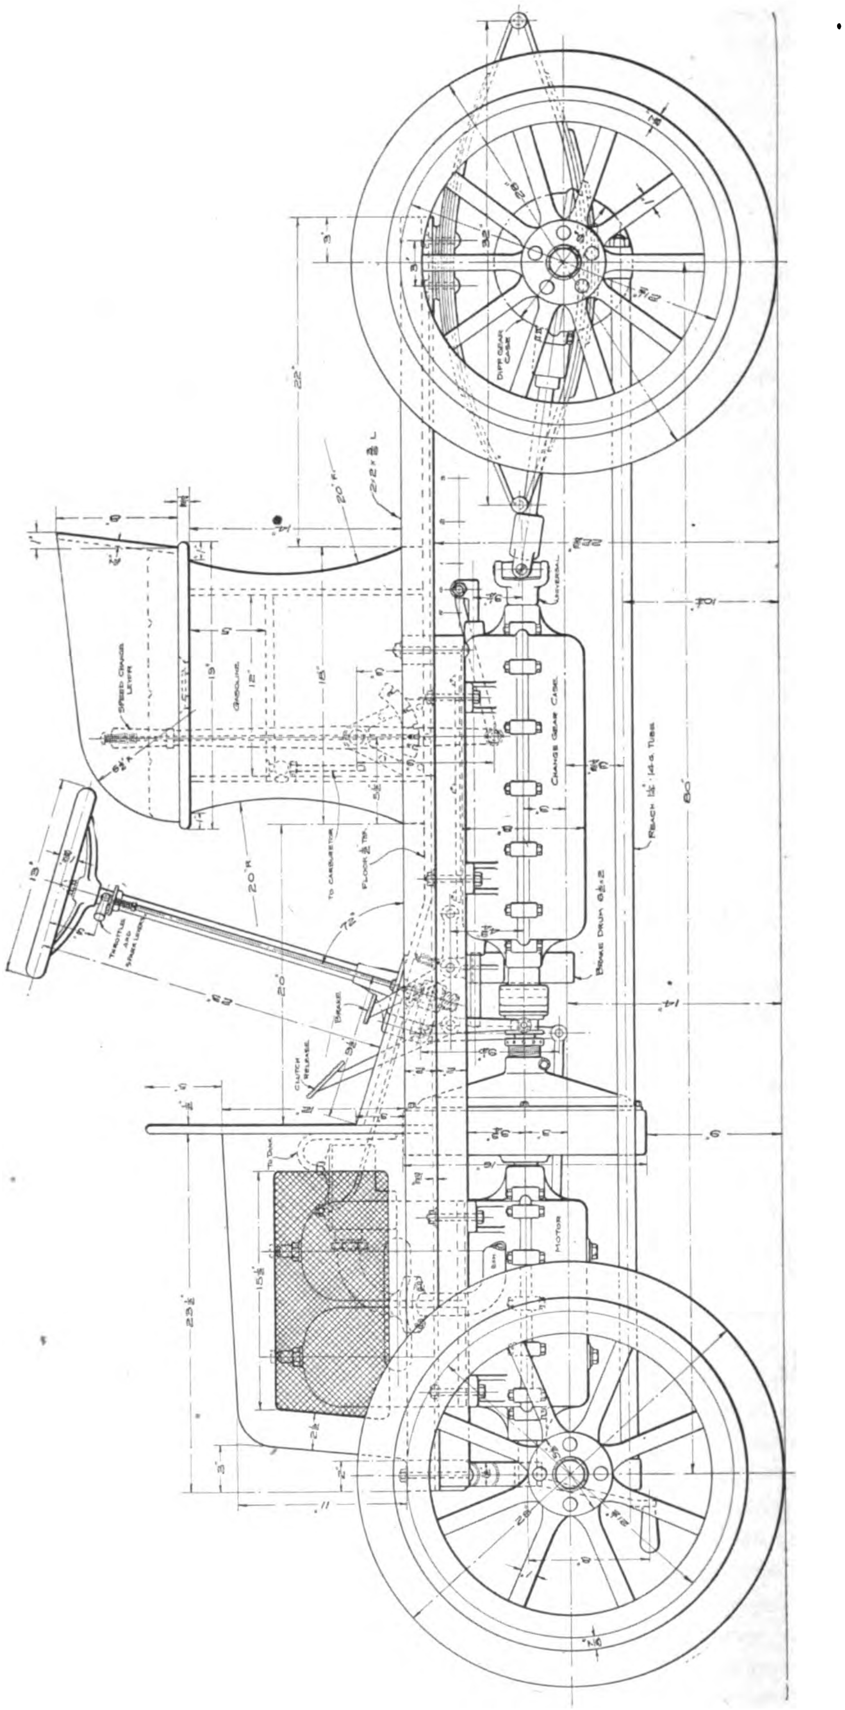

FIG. 1.—SIDE ELEVATION OF COMPLETE MACHINE.

This view also shows a section of one of the wheels, which brings out the construction of the hub and the form of the rim and tire, the latter two being of standard section and dimensions. The construction of the seat is also indicated in the view; it will be noted that the sides are inclined outwardly and come inside the flanges of the angle iron frame at the bottom, being fastened thereto by means of screws. The steering column is shown on the right-hand side of the machine, as this side is considered in common practice to be the best for operating the machine.

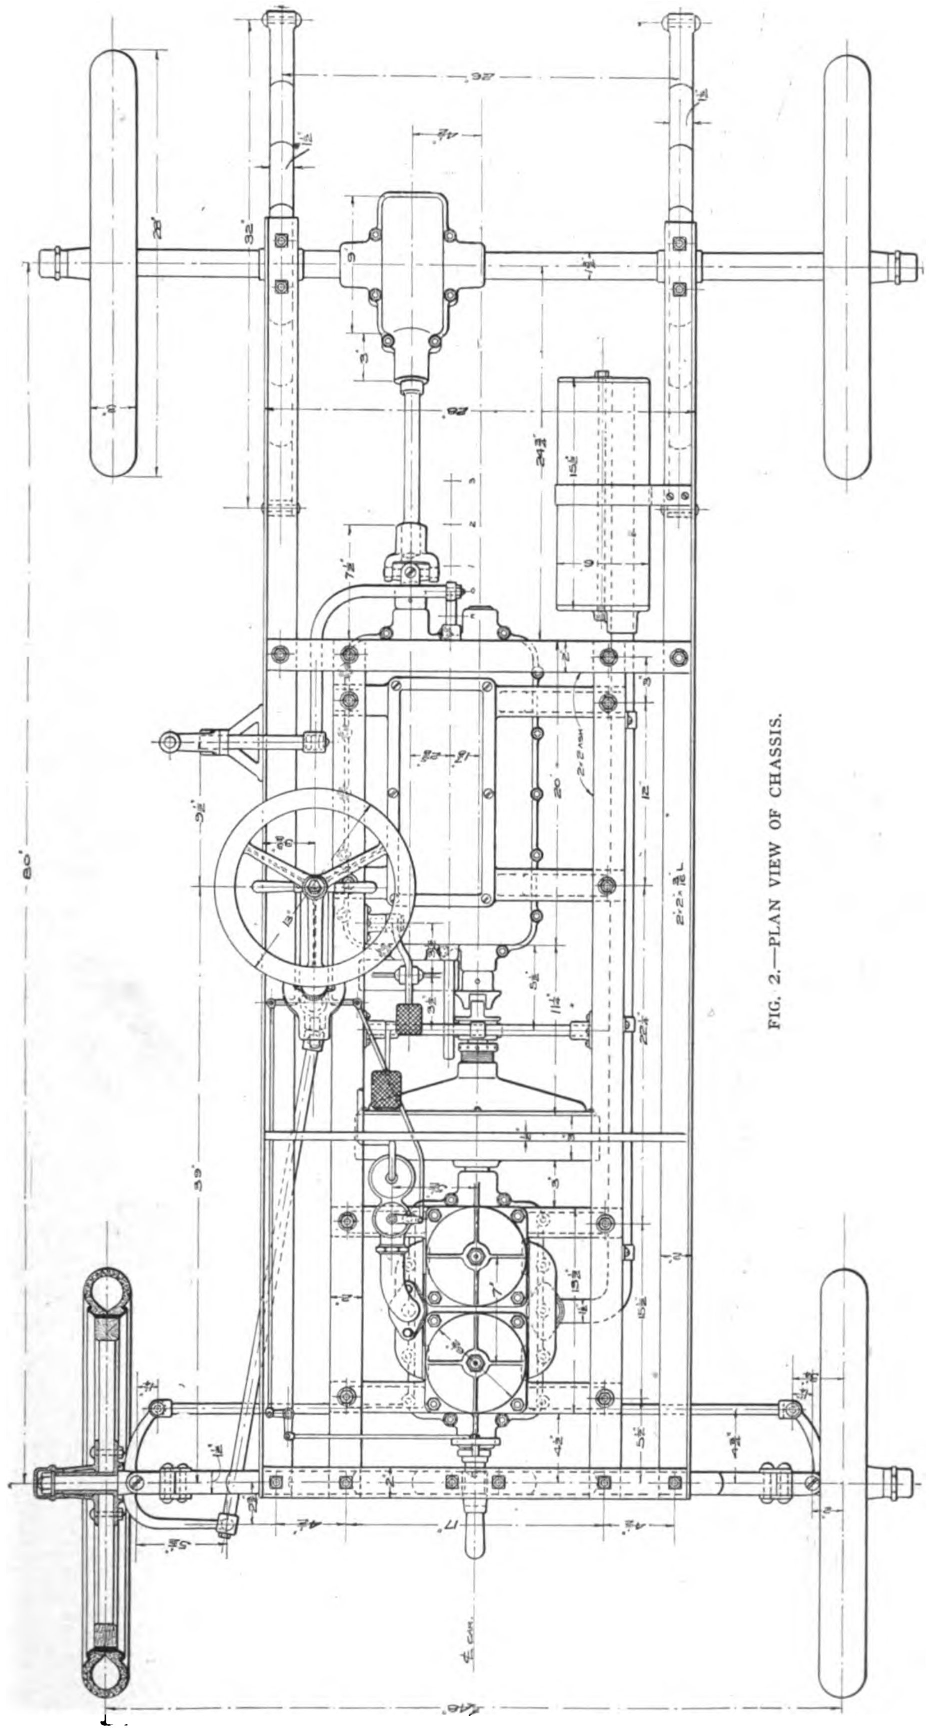

FIG. 2.—PLAN VIEW OF CHASSIS.

Fig. 2 shows a plan view of the chassis. This shows all the operating parts in their proper relation and is probably the best drawing to work from in assembling the machine. The frame is composed of two lengths of 2-in. x 2-in. x 3/16-in. angle steel, each 84 inches long. Across the front is bolted a piece of 2-in. ash which is shaped to fit the spring; ⅜-in. carriage bolts may be used for this, and a washer should be used under the nut to prevent it from cutting into the wood. Bolted to the under side of this cross-piece in front are two longitudinal frame members of 2-in. x 2-in. ash, to which the motor and change gear case are bolted. The rear ends of these longitudinal members are supported by a 2-in. x 2-in. cross-piece, which is in turn bolted to the bottom flanges of the angle-iron frame. The clutch release and brake pedals, it will be seen, are swung on rods attached to the wood frame members. The curved connecting link which moves the sliding gear shifter and connects with the hand lever is clearly indicated in this view. It is made of the peculiar shape shown in order to avoid interference with the frame members.

The exhaust pipe and muffler, which are represented as broken away in Fig. 1, are shown in position in this view. The exhaust pipe consists of a length of 1½-in. steel tubing, bent to suit the frame members in front and fastened thereto by means of small clips of ⅛-in. x 1-in. iron. The muffler is simply a hollow sheet metal cylinder, with cast heads bolted in by means of a through bolt and perforated with numerous small holes on the under side; the aggregate area of the perforations should be about equal to the area of the exhaust pipe in order to avoid undue back pressure. It is probable that a length of common 6-in. stove pipe will answer for the cylindrical part. If this is found to have an undesirable amount of resonance, it may be wound with wire, which will stop the vibration of the walls and will also help to strengthen them. It will probably be necessary to have a cross member in the frame at the extreme rear. The frame is left long in the rear to allow for the addition of tonneau seats if the builder finds them desirable.

The Motor.

Fig. 4 is a front vertical section through the completed motor, which shows the location of the various ports and passages. The motor has no valves and the pistons act as valves, opening and closing the inlet and exhaust ports in the usual manner of two-cycle motors. The cylinders are 4 inches bore by 4 inches stroke. The crank case is divided into halves along a horizontal plane and is of comparatively small diameter, the fly-wheel being placed outside. Arms are cast on the top half of the case, by means of which it is bolted to the frame of the car so as to afford proper clearance for the rotation of the fly-wheel. The pistons are long and have three rings for packing, which are made wider than the ports in the cylinder walls to avoid any liability to catching.

Both the inlet and the exhaust sides of the cylinder are provided with branch pipes; the connections for the main pipe in each case should be inclined to the axis of the cylinder, as shown in Fig. 5. The spark plugs are tapped into the center of the cylinder head, where they are in a good position to ignite the charge and are also accessible for inspection and cleaning when this becomes necessary.

Fig. 5 is a semi-sectional side view of the complete motor. This shows the transfer passages connecting the cylinder with the crank case and also the shape of the deflecting vanes on the piston head. The contact maker is shown on the front bearing boss and is adapted to be rotated about the cam through a certain angle, thus varying the period of ignition in the customary way. The shaft is extended somewhat on this end for fitting on the starting crank.

Fig. 6 gives the details of the cylinder: these should be cast of good close-grained gray iron, and the bore should be finished as smooth and true as possible. The cylinder wall is 5/16 inch thick and is provided with 23 cast flanges, 15/16 inch high, for cooling. The vertical section shows the size and proper location of the ports, the transfer ports being two in number ¼-in. x 1¼-in. opening, and the inlet and exhaust ports are each 5/16 in. x 2 ins.

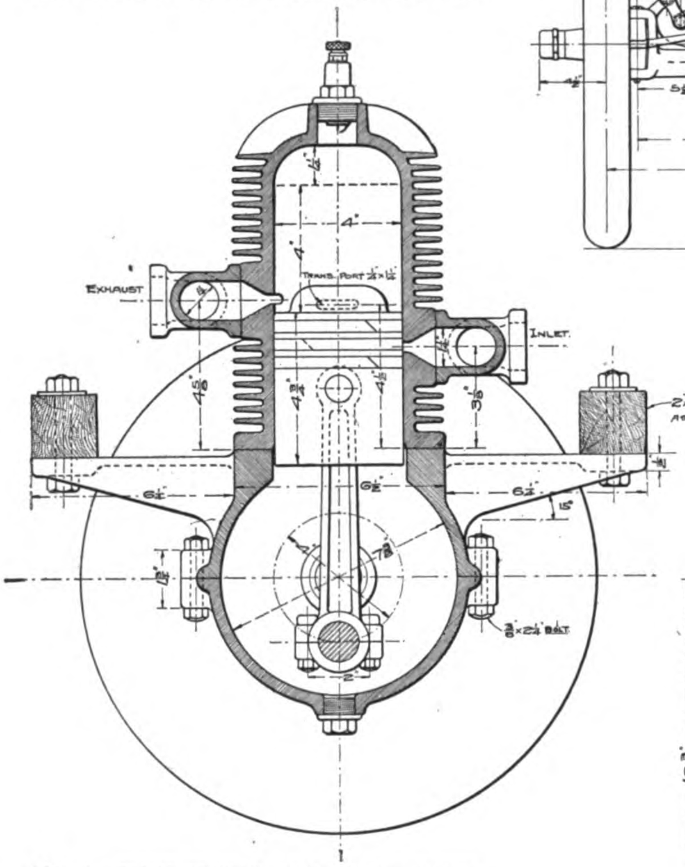

FIG. 4.—FRONT SECTION OF GASOLINE MOTOR.

Fig. 7 is a detail of the piston; it has three grooves turned for ⅜-in. rings. The rings should be turned about 1/64 inch larger than the bore of the cylinder and ⅛ inch thick. They are then cut through with a diagonal slot and should be fitted to the bore so that the ends stand a trifle apart to allow for expansion when they heat up during operation. The body of the piston should be turned about three one-thousandths small for the bore of the cylinder, and the grooves should be turned a nice fit for the rings, which can then be snapped into place and pinned to the piston so that the joints will not be required to traverse that portion of the cylinder which is broken by the ports. The wrist pin is ⅞-in. cold rolled steel and is held in position by two ¼-in. set screws in the inwardly projecting bosses.

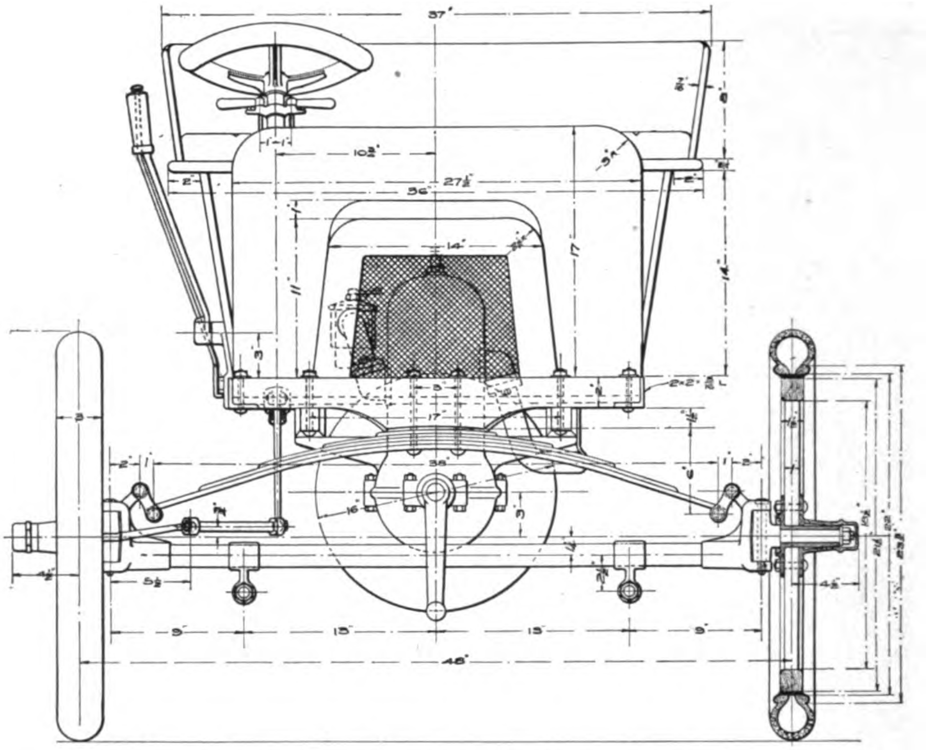

FIG. 3.—END ELEVATION OF COMPLETE MACHINE.

Fig. 8 is a detail of the connecting-rod. This is intended to be a phosphor-bronze casting. Provision is made at both ends of the rod for taking up water. The body of the rod is of "I" section with a 3/16 in. web.

Fig. 9 shows the crank shaft. This is preferably made from a solid open-hearth steel forging, the cranks being cut from the solid metal. Figs. 10 and 11 show respectively the top and bottom halves of the crank case. These are intended to be cast in

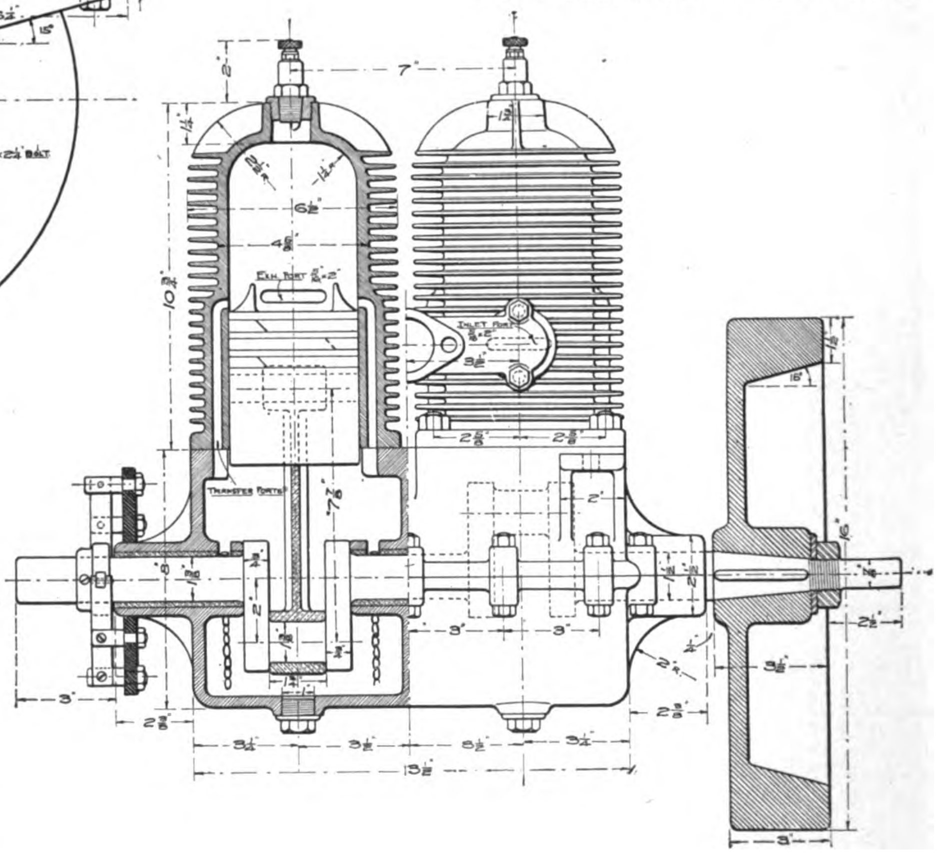

FIG. 5.—SIDE SEMI-SECTION OF GASOLINE MOTOR.

aluminum alloy containing about 25 per cent zinc. The halves should be planed and carefully surfaced where they bolt together; this joint should be perfectly gas tight, and it is preferable not to use packing but to rely on the surfacing and the bolts for drawing the parts in close contact.

Fig. 12 is a detail of the contact maker for use with jump spark ignition. A spark is required in each cylinder once in each revolution, and since the cranks are at 180° the contacts are also arranged 180° apart. The plate upon which the contacts are mounted is bored for and centered upon the main bearing boss. This plate may be made of aluminum or brass and only the stationary contacts need be insulated from it. That is to say, the spring blades are grounded on the engine frame, which is a necessary part of the scheme of connections.

the sparking apparatus. A separate coil is required for each cylinder. For spark coils and plugs the builder will do well to purchase standard articles. Also in regard to the carburettor, it is probable that more satisfactory results will be obtained from a ready-made article than from one of the home-made variety.

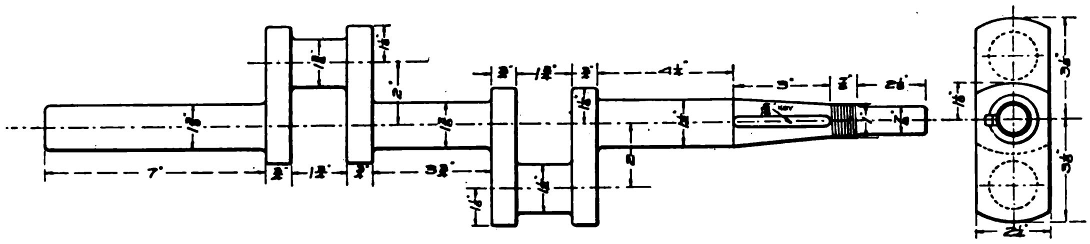

FIG. 9.—DETAIL OF CRANK SHAFT.

Fig. 14 shows the details of the motor fly-wheel and clutch. The wheel is of cast iron and is to be turned all over, the inner surface of the rim being finished to a 15-deg. taper and forms the female portion of the cone clutch. The male portion of the clutch is a disc of aluminum alloy faced with leather and riveted to a steel center which is bored to fit the reduced end of the crank shaft. A spiral spring forces this disc into contact with the fly-wheel surface, so that the cones are always in engagement except when the clutch pedal is depressed while changing from one gear combination to another. The spring pressure thus applied is entirely self contained and does not produce any end thrust upon the motor or change gear bearings, due to the fact that the fly-wheel is covered by a cap which takes care of this thrust and at the same time forms a dust-proof cover for the parts. In order to disengage the clutch the shaft carrying the male cone must have an endwise motion of about ½ inch, which is allowed for in the jaw clutch that connects the motor shaft to the speed change gear.

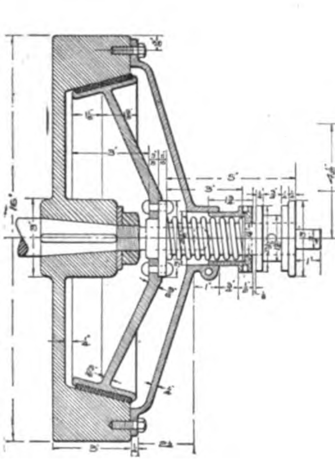

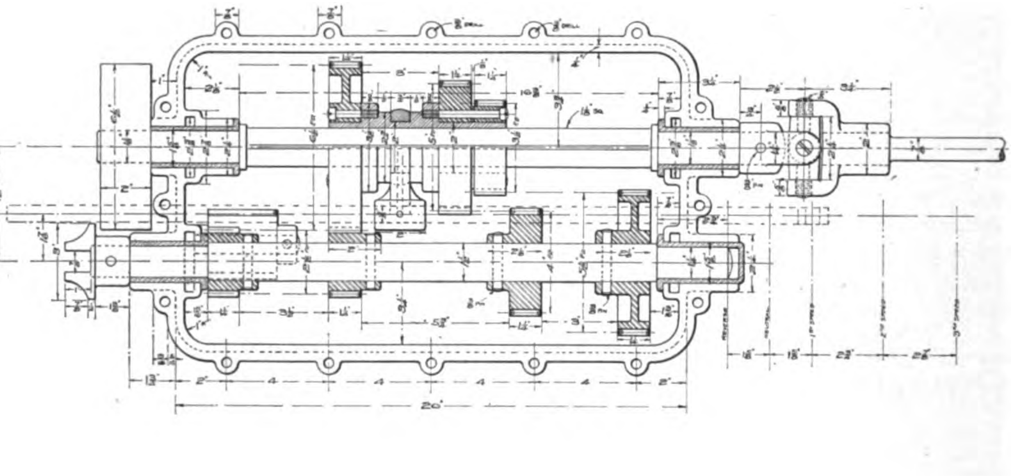

FIG. 14.—DETAIL OF FLYWHEEL AND CLUTCH; AND PLAN VIEW OF CHANGE GEAR CASE— FIG. 15.

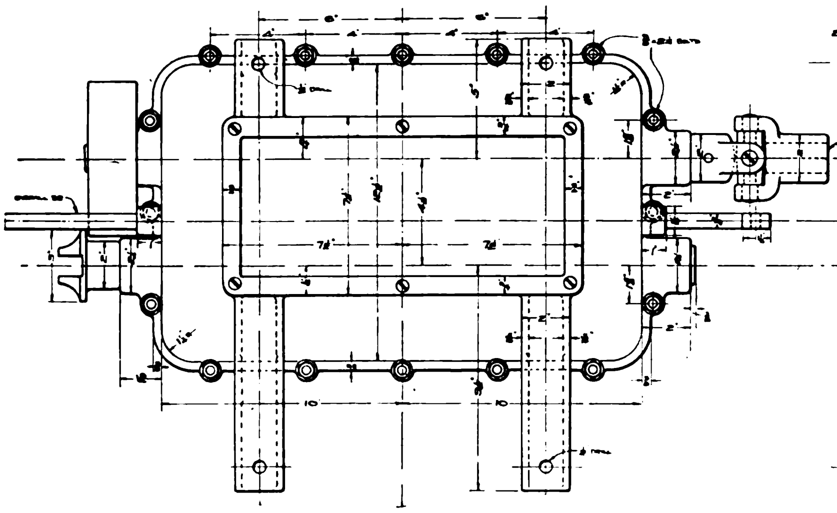

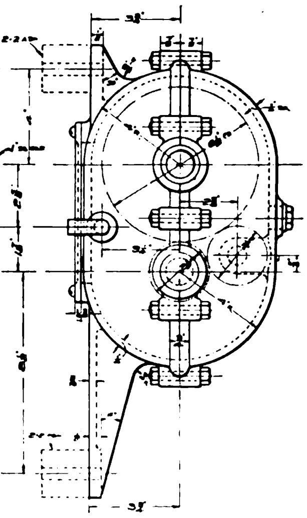

FIG. 16.—PLAN AND END VIEWS OF COMPLETE CHANGE GEAR CASE—FIG. 17.

Transmission Gear, Axles, etc.

Fig. 15 shows the speed change gear, with the top half of the case removed to make clear the arrangement of the gears and their operation. The driving shaft is round and has secured to it by means of pins four gears of different diameters. The driven shaft is square and has mounted upon it a spider carrying three gears of suitable diameters to mesh with the gears on the driving shaft. The spider may be slid endwise along its shaft so that any desired pair of gears may be engaged. The drawing shows the gears engaged for the first forward speed, which gives the highest ratio of engine turns to rear wheel revolutions. The reverse speed gives the same ratio as the first forward speed except that an idler gear is interposed between the driving and driven shaft, thus changing the direction of rotation. The reverse gear is obtained by moving the gears to the left of their position in the drawing and the two other forward speeds are obtained by moving the spider to the right of its present position. The center lines at the extreme right of the figure indicate the exact distances through which the

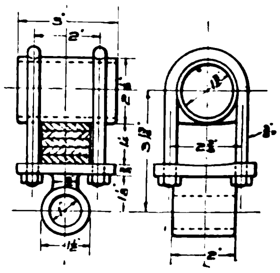

FIG. 19.—DETAIL OF REAR AXLE SPRING CLIP AND REACH-FITTING.

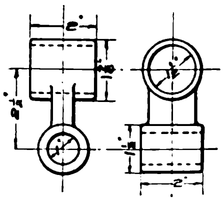

FIG. 21.—DETAIL OF FRONT AXLE REACH-FITTING.

shifter rod must be moved to get the various combinations. The universal joint which transmits the motion to the rear axle gear and also the brake drum are shown in this view. The accompanying table gives the data for gear ratios and sizes of gears for various combinations:

Table 1.—Change Gear Data.

Speed.	Pitch diameter of gears. Driving shaft.	Pitch diameter of gears. Driven shaft.	Gear ratio.	Total gear ratio to rear axle.	R.p.m. rear wheels.	Car miles per hour.	Motor r.p.m.
Reverse and 1st	2½"	6½"	2.6	10.4	72	6	750
2nd	4	5	1¼	5	144	12	720
3rd	5½	3½	0.635	2.55	300	25	765

Bevel gear ratio 4.1. Change gears, 8 pitch.

Fig. 16 is a top view of the complete gear and case, showing the lengths of arms for bolting to the frame work of the car, the shifter rod, brake drum, removable cover, and universal joint. Fig. 17 is an end view of the gear case, which helps to make clear the position of the idler gear by means of which the reverse speed is obtained. It also shows the screw plug at the bottom of the case, through which the old oil may be drained off. The case should always be partly filled with a heavy oil and the gears and bearings are then lubricated automatically. The best practice indicates that all gears should be cut from machine steel, have the teeth rounded or beveled on the edges, and then case hardened. If for any reason this is impracticable, phosphor-bronze might be used, though it will not, of course, wear as well. Cast iron is, of course, out of the question, as it is so brittle that the teeth would be likely to strip in changing speeds.

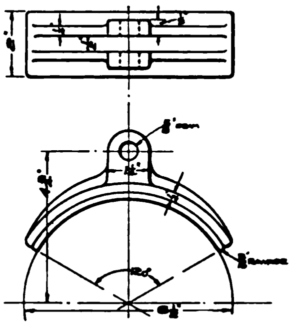

FIG. 26.—DETAIL OF BRAKE SHOE.

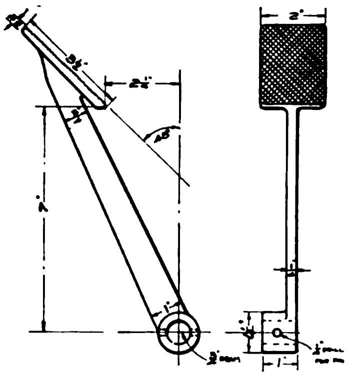

FIG. 23.—DETAIL OF CLUTCH RELEASE PEDAL.

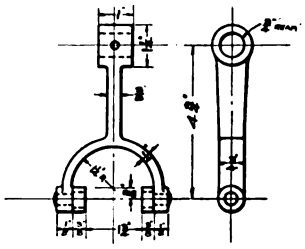

FIG. 24.—DETAIL OF CLUTCH FORKED LEVER.

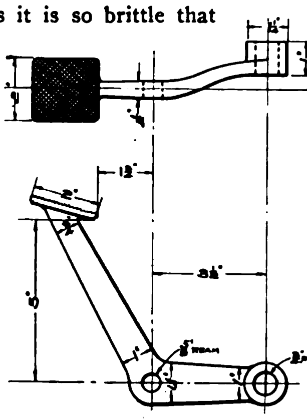

FIG. 25.—DETAIL OF BRAKE PEDAL.

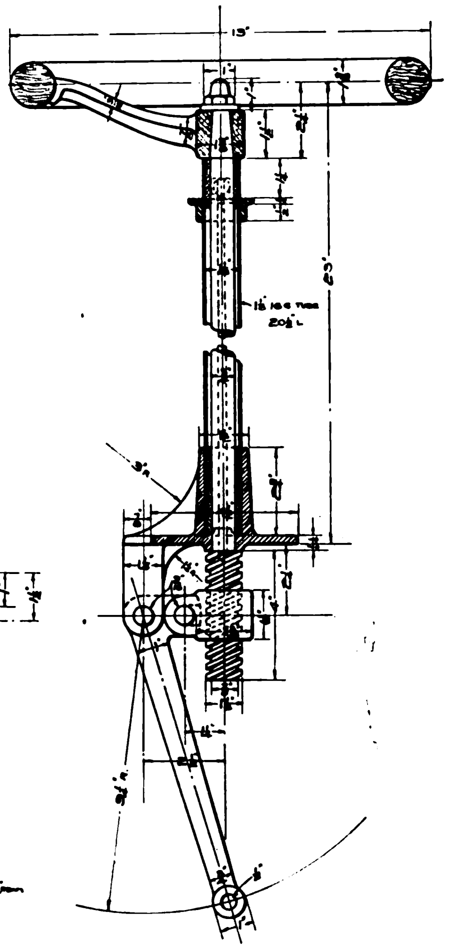

FIG. 22.—DETAIL OF STEERING COLUMN.

Fig. 18 shows the construction of the rear axle and the bevel gear drive. The revolving portions of the axle are of 1⅛-in. solid steel turned down to 1 inch at the hubs and keyed in. The differential gear is of standard construction and is therefore not detailed. The hubs may conveniently be of phosphor-bronze or steel. The gear case is intended to be cast of aluminum alloy containing 25 per cent zinc. The same is used for the engine crank case and the change gear case. The revolving portions of the axle are enclosed in a 1¾-in. steel tube which is fitted with phosphor-bronze bushings at its extremities. It will be noted in this connection that only plain bearings are used all through the construction of the car. Fig. 19 is a detail of the spring clip fitting

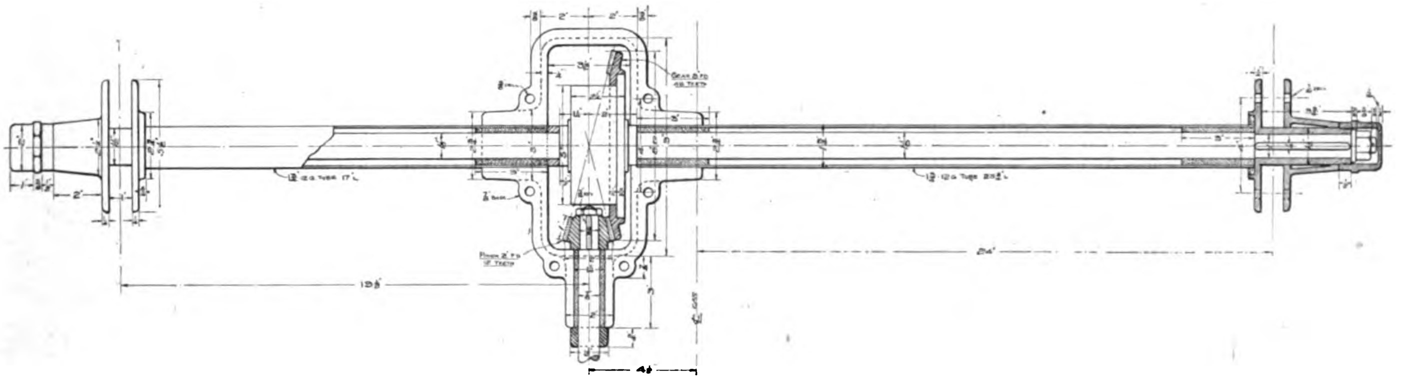

FIG. 18.—DETAILS OF REAR AXLE AND BEVEL GEAR.

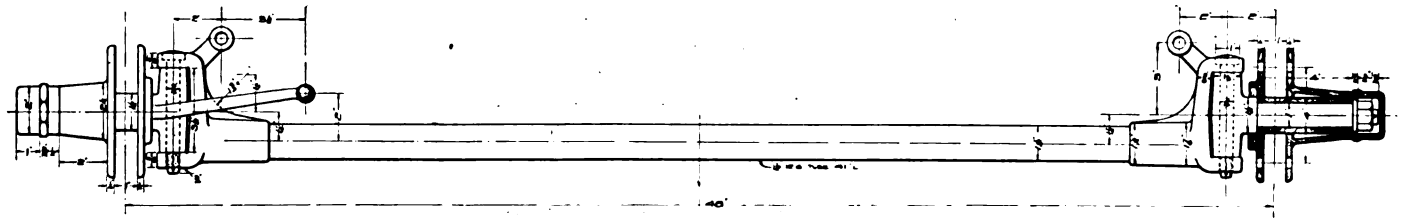

FIG. 20.—DETAIL OF FRONT AXLE.

for the rear axle. This consists of a steel casting which is bored to fit the axle tube and is clamped thereto and to the spring by means of a pair of ⅜-in. "U" bolts.

Fig. 20 shows the construction of the front axle and hubs. The axle consists of a length of 1½-in. tube brazed into the forked steering ends. The front hubs are the same as the rear ones, with the exception, of course, that they are bored a running fit for the axle instead of being keyed on. Further details of the axle ends can be obtained from Fig. 2. Fig. 21 shows the reach fitting for the front axle. This is bored to fit the front axle tube and the reach is intended to be a turning fit for the lower portion so that the running gear may adjust itself to any unevenness of the road. The reaches consist of a pair of steel tubes, the location and length of which may be seen in Fig. 1. They have solid ends brazed in and a nut is placed on the outside.

Fig. 22 shows the construction of the steering column. The tubular portion is stationary and has attached to it near the top the spark and throttle levers; the center rod turns with the hand-wheel and operates the screw at the bottom. The screw is 1⅛ inches outside diameter and has three threads with a pitch of one thread per inch. The proportions of the linkage are such that about one and one-half revolutions of the hand-wheel are required to turn the front wheels from one extreme to the other.

Figs. 23 and 24 show respectively the clutch, release pedal and the forked lever for disengaging the clutch. The latter has a pair of small rollers on the forked ends, which engage the grooved collar on the clutch shaft for drawing the cones apart. Fig. 25 shows the brake pedal. This, as well as the clutch pedal, should preferably be a steel forging. Fig. 26 shows the brake shoe, which may be a casting of alzinc and is faced with leather for the friction surface. This may be secured to the metal surface of the shoe by means of shellac and a considerable number of wooden shoepegs. The wear on this facing will probably be rapid, but it can be easily and cheaply renewed.

TELEPHONE TRAFFIC DEPARTMENT METHODS.

BY CHARLES H. COAR.

Time was when the traffic department of a telephone exchange was considered of minor importance, and no great efforts were exercised to ascertain the condition of the exchange service; whereas to-day it is considered of the utmost importance if efficient results are to be obtained from the operating staff.

Considering the fact that the wages of the operating staff constitute a principal item of expense in exchange maintenance amounting to approximately $3 per telephone a year in a modern central energy system of 5000 subscribers, one ceases to wonder at what possible benefits could accrue from the seemingly insignificant data obtained by the traffic department.

Good service in a telephone system can only be had when good transmission, reliability, promptness and civility exist, and none of these qualities could be dispensed with without a decided detrimental effect. Good transmission is necessary, of course, if service is to exist at all, while reliability, promptness and civility can be considered of relative importance. Assuming that efficient apparatus is installed, these last three qualities will be found to depend on the selection, training and management of the operators, and incidently on the conditions imposed.

The selection of girls for positions as operators should be done by persons with ability to read character, and by a woman, since she can request information without causing embarrassment.

It is not advisable to accept girls under 18 or over 25 years of age, and all applicants should furnish references as to past employment, and if upon examination they fulfil the necessary requirements such as sight, hearing, voice and reach, a record should be kept of each applicant containing the address and other desirable information concerning the applicant's examination, character and impression, together with the date of application.

These records form a handy reference and enable the traffic department to summon such candidates as are deemed desirable when necessary.

Certain traffic departments of the larger exchanges have spared no expense in obtaining the best facilities for training their operators, and the results obtained seem to justify the expense.

A successful applicant should first be taught the rudiments of the telephone, so as to know the difference between a transmitter and a receiver, what is meant by the terms used in the operating room, how to handle the cords and plugs in making a connection, how to converse over the telephone, and also how to become ambidextrous. This latter is a feature that is especially noticeable in many of the larger exchanges by its absence. Operators who are supposed to be perfect, will be found imposing on their right arm, while the left is used only in cases of necessity.

When the applicant is sufficiently trained in the rudiments, she may be placed at a position, having a receiver provided for her which is connected with the regular operator's set at this position, and in this manner she should soon become familiar with the requests of subscribers and the methods used in answering and making connections. She may then be allowed to operate a dull position under the supervision of a regular operator, until such time as she is thought to be competent to operate a position unaided. A night shift is usually assigned to her, then the future of course depends wholly on her own ability.

Applicants who have been previously employed as operators in small exchanges, as a rule, do not become good operators in a large exchange, for it is characteristic of this class to believe themselves fully competent, so that they view these preliminaries as needless. Persons well versed in traffic department methods consider it much more preferable to school their operators from the raw material, so as not to have any predetermined opinions or methods on the part of applicants to contend with.

Civility is one of the essential qualities required of a competent operator—that trait of being able to turn away wrath by a soft answer. Nagging and scolding of operators by the monitress should not be tolerated.

If at any time it becomes necessary to severely criticise an operator, it should be done so that the remaining employes will not hear the conversation. Many good operators become nervous every time a monitress stands near them, for the reason that they have formed the idea that a monitress is there to note all their deficiencies, and for this reason some lenience should be shown the operator, in accepting a monitress's report. When a monitress observes a position being nicely operated, there should be no hesitation on her part in informing the operator at this position of the fact; for the praise thus bestowed will make itself evident in the renewed efforts of the operator to please.

Everything taken into consideration, the idea of compensating the operators according to their service tests is a good idea, but it is not advisable to hold back part of their salary in case the service test is poor. The employe should know she is to have a certain amount due her on pay day regardless of the service test, which if excellent should be rewarded by a slight increase for this particular month. The matter of wages and extra compensation for good service tests must necessarily be confined to local conditions.

In an exchange where the service is strictly unlimited on party lines, it is customary in practice to expect a competent line-position operator to be able to complete about 200 calls per hour, but this is true of only certain positions during their busiest hours. In making this statement only the modern central-energy switchboard is considered.

Cases are said to be on record where a line-position operator completed 500 calls in one hour and a trunk operator 1000 calls in the same period.

In exchanges where the service consists of individual, party, measured and pay-station lines, it is generally conceded that the completion on an average of from 170 to 190 calls per hour is good operating. There are systems in which automatic counters are inserted in the cord circuits, which tend to lighten the operation of measured service lines, but in the majority of exchanges having this class of service either slips are recorded by the answering operator or a register is operated by the calling subscriber at his instrument. Where this class of service exists the operating would be necessarily slower. It becomes necessary at times in enchanges having several classes of service to distribute a portion of each kind of service throughout the different operating positions, in order that no particular position will be difficult for one operator to handle. It is usual, however, to classify the subscribers' numbers as much as possible with the kind of service they have, allotting the lower numbers to the individual service. By means of the peg count, information relative to this distribution is obtained, which enables the traffic department to distribute the lines in such manner as to give the best possible results.

By peg count is meant the recording of all calls occurring in an exchange for a period of twenty-four hours, in such manner that the total number of calls occurring at one or all the positions may be ascertained for this period. It is customary in most exchanges to have a peg count in the earlier part of the month, between the 5th and 15th, from 12 to 12. In making a peg count the operators record the calls either by pencil and paper or by moving a peg in the jacks, or by a small tabulating meter, which is the quickest as well as most convenient. An individual meter, operated mechanically, is provided for each operator. It has occurred to the writer that a small tabulating meter, such as could be fastened and operated in the palm of the hand, would be very convenient for this purpose, if properly constructed. The calls could then be recorded during any of the customary movements used in operating, say by a thumb pressure of the hand containing the meter, thus doing away with the extra movements now required in most methods.

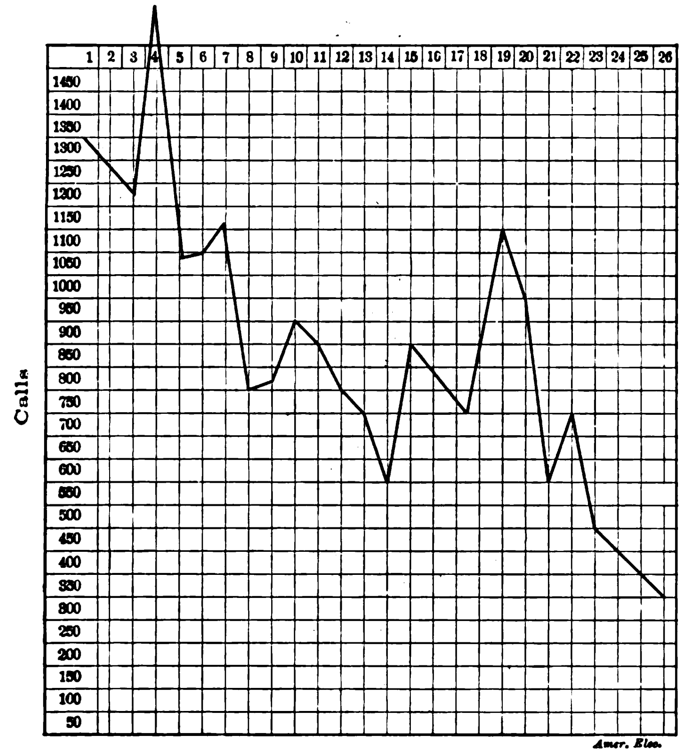

FIG. I.—PEG COUNT FROM EXCHANGE OF 2200 SUBSCRIBERS.

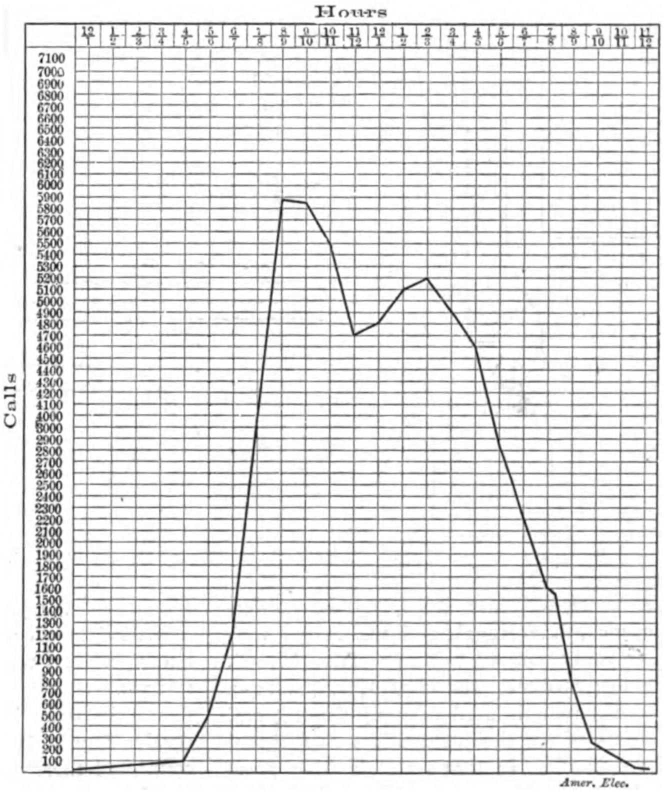

FIG. 2.—24-HOUR CHART SHOWING TOTAL CALLS RECEIVED.

After obtaining the number of calls at each section for the period of twenty-four hours, a curve is plotted, as shown in Fig. 1, which is useful in determining what positions are overcrowded or otherwise.

It has been demonstrated many times that one-eighth of the total number of calls occurring at a position during twenty-four hours is approximately the number of calls occurring at that position during its busiest hour, and the same proportion applied to the calls of the entire switchboard gives fairly good results in ascertaining the total number of calls during the busiest hour.

The curve shown in Fig. 1 gives the number of calls answered at each position for a period of twenty-four hours, the numbers at the top designating the different positions, while the figures in the left column represent the number of calls. The heavy black line is termed the load curve, and it is by plotting this curve that the positions overcrowded or otherwise are plainly shown.

It will be noted that a very poor distribution of lines existed where this peg count was taken, for it will be seen that there occurred at the first position approximately 1350 calls during the twenty-four hours, at the fourth position 1600 and zigzaging throughout the different positions to the small number of 400 calls at the twenty-fifth position. This exchange had about 2200 subscribers at the time this peg count was taken, with a total number of calls as compiled from the chart of 22,600, thus allowing slightly over 10 calls per telephone during twenty-four hours, which is found to be a fair average in general practice. By properly distributing these total calls, sixteen operators would be quite sufficient for efficient operation during the busiest hour, and quicker service would result, for dull position gives slow service, because it is very noticeable that an operator at a dull position gives slow service because she has not enough calls to complete, which would tend to make her alert and active. It is customary to find the first sections in a switchboard crowded, while others have hardly any lines.

Where this condition exists, the traffic department plans a distribution of the lines, causing the operators to have a mixed class of service to answer, that is, business and residential lines, for in this manner the load is more evenly distributed throughout the board, resulting ofttimes in diminishing the operating force, as well as increasing the efficiency of the service.

The chart shown in Fig. 2 is compiled from the peg count of an exchange of 5000 subscribers, and shows the total number of calls occurring in the exchange during any of the twenty-four hours in which the count was taken. The numbers in the space provided at the top represent the individual hours, starting from 12 to 1 a. m. at the extreme left and reading by hours to 11 to 12 p. m., space being provided for twenty-four hours, while the figures in the left column designate the number of calls. The heavy black line shows the disposition of the calls answered. Thus during the busiest hour, which occurred, as shown, between the hours of 8 and 9 a. m., the total number of calls answered was 5900, while during the dull period or midnight but a few calls were answered. In some exchanges, the dull period occurs between the hours of 2 and 4 a. m.

Charts of this description bring out much clearer the particular needs required for the betterment of the service than a column of figures, and upon filing these charts away, a ready means of comparing the results of the different months is obtained.

A great many different methods are used to secretly test the operator's ability and manner of answering subscribers, consisting mostly of circuits so designed that the person doing the testing may listen on the operator's set without her knowledge. These circuits terminate in jacks at the chief operator's desk, in many instances, where a special receiver, ranging from 2500 to 5000 ohms in resistance, is used in listening. It is necessary to employ a high resistance receiver, because most operators' hearing is very acute, enabling them to know when any one is listening on their set by the change in sound, which is not appreciable when a high resistance receiver is applied thereto.

In order to get a fair test of the subscribers' service it is necessary to select a group of lines and observe them during a certain period of the day. The number of groups and lines would be determined by the size of the exchange, but a fair portion should be selected so as to give a good average of the general service.

The circuits shown in Fig. 3 illustrate a test which is very efficient and also applicable to most systems from the intermediate rack. In Fig. 3 the circuit *A* represents the subscribers' line, multiple jack, answering jack, line signal, and the relays with their connection to this apparatus through the intermediate rack clips 1, 2, 3 and 4. The *B* circuit is used to apply the test and consists of the flexible conductors 1, 2 and 4, terminating in snaps and binding posts preferably as shown, and a jack having connected to its inner or rest contacts a 1000-ohm drop and a condenser in series; also a line signal lamp, a high resistance receiver terminating in a plug, and the receiver jacks and connecting cord. From fifteen to twenty-five of such circuits shown in connection with the flexible conductors 1, 2 and 4 may be mounted similarly to a small switchboard for convenience in handling. One receiver with the jacks and connecting cord would of course suffice for this group. This group of circuits may then be connected to an equal number of lines at the intermediate rack, by means of flexible conductors and snaps, applying the numbered snaps to the corresponding rack spring.

The different line signals of this group are supplied by a common terminal with sufficient current to light them, but this could easily be obtained at the rack. The subscribers' line numbers which are selected for testing should be recorded as they are connected to the test set, in order that the person doing the testing will know what line numbers are connected to the various test circuits.

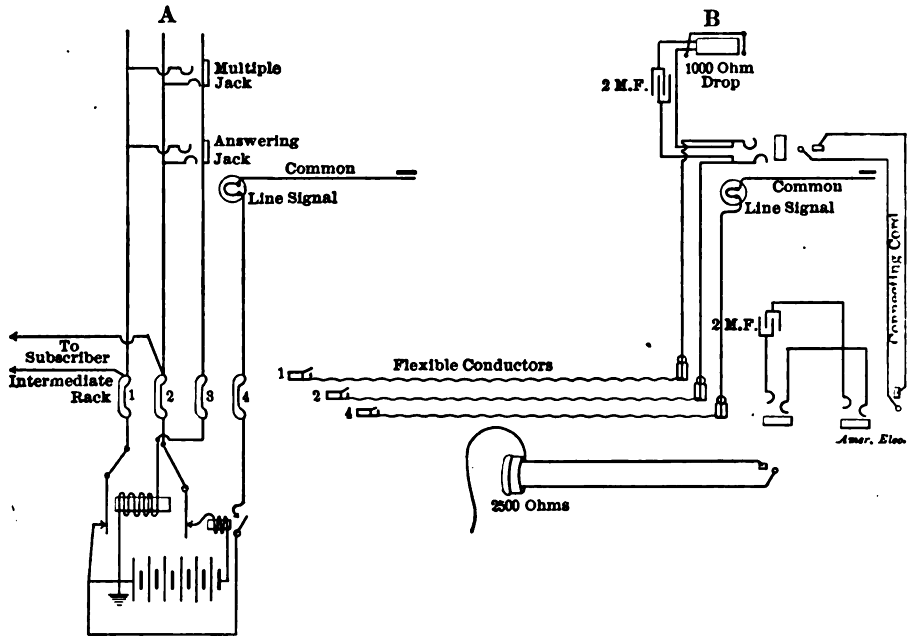

FIG. 3.—DIAGRAM OF TESTING CIRCUITS.

Assuming the lines connected, it will be evident upon tracing the circuits shown in Fig. 3 that as soon as one of the connected subscribers removes his receiver, the switchboard line lamp and the corresponding test circuit lamp will both light, and when the answering operator inserts a plug into this switchboard jack, both lamps will be extinguished, owing to the operation of the cut-off and line relays in the customary manner. The person doing the testing will thus be able to ascertain when one of the connected subscribers desires central, and by plugging the high resistance receiver into the proper jack can collect the desired data concerning the time consumed and operator's manner of making the connection.

The drops in the test circuits are used to receive any calls occurring over the lines connected thereto, enabling the person doing the testing to collect data concerning the manner of ringing subscribers, and other data such as could be obtained by listening on these circuits. The circuits being simple should present no difficulties, whatsoever in securing a fair test of the exchange service in general.

Circuits similar to these can be installed at the chief operator's desk, and complaining subscribers may be connected to them, for the purpose of bringing these lines under direct observation of the chief, in order that she may observe their service during complaints.

A variety of opinions exist regarding the length of time it should take for an operator to request "Number," after the subscriber's signal is shown, but in most systems an average of three seconds is considered good, although in many instances where comparatively easy operating exists, the elapsed time is even shorter.

A form having space provided for the following data concerning 50 or 100 lines will be found useful in recording the results obtained by using the circuit described.

a—Number of line.
b—Time of calling.
c—Time consumed by operator in inserting plug.
d—Time consumed by operator in requesting number.
e—Words used.
f—Number of subscriber called for.
g—Time called for subscriber's answer.
h—Length of conversation.
i—Time consumed in taking down connection.
j—Time consumed in reporting line busy.
k—Time consumed in reporting don't answer.
l—Time consumed in reporting out of order.
m—Manner of ringing.
n—Call lost.
Totals and average.

If these items are properly filled out and an average taken, a fairly accurate report of the services in general is obtained, although space is only provided for the more important operations.

A CONVENIENT LAMP BANK.

BY GEO. T. HANCHETT.

A portable resistance which is readily renewable and subdivided into units, may easily be made from a bank of incandescent electric lamps; and by the employment of lamps of the bung-hole type, such a bank can be made exceedingly compact. The lamps are preferably placed in a box equipped with binding posts and a carrying handle and hinged so that the top and sides can be opened when the bank is in use so as to rapidly dissipate the heat developed.

The accompanying illustration shows a bank of eighteen 16-c.p. lamps arranged in two rows. These may be connected either in series or in multiple on a two-wire or a three-wire system, and the actual resistance of either row varied by unscrewing a suitable number of lamps.

The applications of such a device are so numerous that it would be out of the question to mention them all, but some of the most important follow.

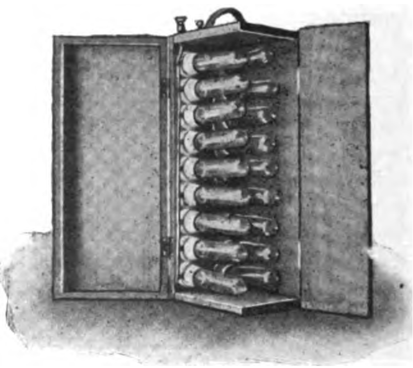

FIG. 1.—LAMP BANK.

As a load for small meters the apparatus is most convenient, since it can be applied to either two or three-wire meters and is always under control. In cases where it is desirable to test a large three-wire meter with the neutral wire disconnected and without interfering with the regular commercial load of the meter, such a bank connected in series across the line as a supplementary load (the neutral wire beyond the meter being connected to a neutral point in the lamp bank) is very useful, permitting any discrepancies in the balance of the load to be compensated for by the addition of a suitable number of lamps on the slightly loaded side.

The only suitable way to test the resistance of motor armatures is to cause current to flow through them and measure the drop with a low-reading voltmeter. The available current, however, must be used in connection with a resistance so as to be under control, and a lamp bank of this description is exceedingly convenient and suitable for the purpose.

In designing a field rheostat, especially for motor control, the lamp bank is very convenient for preliminary investigations. By connecting it in series with the field and adjusting the number of lamps in circuit, the limits of speed variation under which the motor can safely operate may be readily found, and an ammeter and voltmeter give the necessary data for a rheostat which will duplicate the results. The cost of making such a lamp bank should not exceed $7.00. It forms a very convenient adjunct to any testing laboratory, and is capable of consuming over a kilowatt. It should preferably be equipped with four watt lamps.

WATER COLUMNS AND LOW WATER ALARMS.

BY R. T. STROHM.

In most places where stationary boilers are installed, it is not convenient to attach the gauge cocks and the gauge glass fittings directly to the shell of the boiler, and yet have them in plain view, or within easy reach, of the fireman. The most common method is to attach both to a separate and distinct fitting called the water column, as illustrated by Fig. 1. The water column, *A*, consists of a cylindrical iron casting, about 4 inches in diameter on the inside, on an average, though it may be as small as 2½ or as large as 5 inches in internal diameter. The thickness, of course, depends largely upon the pressure to which it must be subjected, but owing to the fact that cast-iron is a very unreliable and treacherous material when subjected to tension, the thickness should be ample, with a large factor of safety. This cylindrical column, *A*, is tapped both at the top and at the bottom to receive wrought-iron nipples, *B* and *C*, which connect with the pipes *D* and *E* leading to the steam space and the water space of the boiler, respectively.

These fittings and pipes are all made large, for a very good reason. The water column is intended to give reliable evidence as to the height of the water in the boiler, and in order to do so, its connections with the boiler must be free and open. All feedwaters contain sediment or scale-forming substances, and these, in the process of circulation, are deposited in various parts of the boiler and in pipes leading into it. A clogged water connection to the water column would, of course, render the readings of the gauge glass and the indications of the gauge cocks wrong and unreliable. Hence the use of large pipes, to prevent any such occurrence, within a reasonable length of service. If, however, the column is continually neglected, no care being taken to blow it out at intervals, the bottom connection must eventually clog up. To obviate the necessity of removing the entire column and its connections, in such a case, to permit proper cleaning, a cross, *F*, is used to connect the nipple, *C*, and the pipe, *E*. In the opening opposite the pipe, *E*, a plug, *G*, is screwed, which can easily be removed. Should the boiler connection become filled with sediment, the plug, *G*, is taken out and an iron bar pushed through the pipe until the passage is free from obstruction. A blow-off valve is placed on the pipe, *H*, and the frequent use of this should serve to prevent dangerous deposits of sediment in the water column or in the nipple, *C*.

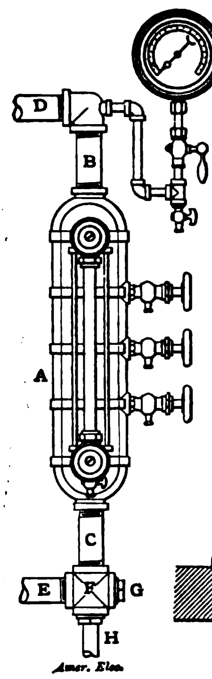

FIG. 1.

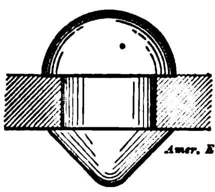

FIG. 2.

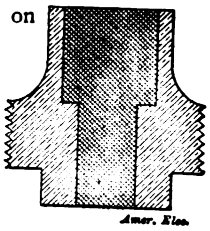

FIG. 3.

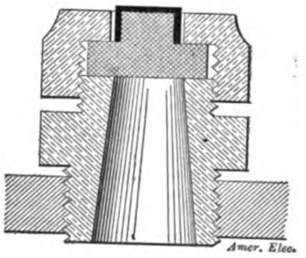

FIG. 4.

The water column is tapped to receive the gauge glass fittings and the gauge cocks. These appurtenances are usually placed in planes at right angles to each other, as indicated, the gauge glass being at the front. It is also customary to tap the column on both sides, so that the gauge cocks may be placed either to the right or to the left of the glass, according to the location of the boiler. The steam gauge is attached to the upper pipe fitting by a ¼-in. pipe so arranged that it may be easily drained or blown out. Draining becomes necessary if the boiler is to stand idle during very cold weather.

It is one of the many duties of the fireman to maintain a safe, and likewise a nearly constant, water level. However, numerous other matters demand his attention, and under these circumstances it is found that the water level in many boilers fluctuates considerably and frequently reaches the danger point. Low water is acknowledged to be a fruitful source of boiler explosions, and to prevent explosions due to this cause, and also to warn the attendant when the water approaches or reaches the danger level, numerous safety devices and alarms have been attached to steam boilers.

Doubtless the simplest of these many precautionary appliances is the fusible plug. It consists of a plug having a core of tin or lead, or of some alloy having a low melting point. This plug is screwed into the shell of the boiler at the lowest safe water level. So long as the plug is covered with water, the heat from the furnace or from the furnace gases is conducted away as rapidly as it is received. But if the water level falls so as to uncover the plug, there is no means of removing the heat, and the soft metal fuses, the pressure inside the boiler forcing out the molten metal and thus forming an outlet for the escape of the steam. This escape of steam calls attention to the fact that the water has reached the danger level.

One method of inserting the fusible plug is illustrated by Fig. 2. A hole about ½ inch in diameter is drilled in the plate, and a rivet of lead or composition metal is driven in and headed. This form is not easily replaced when it has blown out, however, and in this respect the plug shown in Fig. 3 has the advantage, since it may be replaced from the exterior of the boiler shell. As illustrated, it is simply a brass plug, having a center of fusible alloy, screwed into the plate. If it should melt, the empty brass shell is removed and a new plug substituted. In case the water contains corrosive impurities which may affect the soft metal in the plug, it becomes necessary to use a protective cap, as shown by the plug in Fig. 4. In this form, the fusible portion is a button or disc held firmly between the plug body and a removable screw cap. Over the top of the button is placed a thin copper cap which effectually prevents contact of the water and the fusible alloy. Since the top of this plug is considerably above the plate surface, it will give the alarm before the water actually uncovers the plate, thus preventing overheating and bulging of the shell.

The fusible metals used in safety plugs are lead, tin, Babbitt, and alloys of cadmium. All of these have melting points considerably below the temperature of red-hot iron. The United States Supervising Inspectors specify that Banca tin shall be used in fusible plugs; its melting point is about 445° F. They also require the plugs to be at least ½ inch in diameter at the smallest end of the internal opening. The plugs are placed in the bottom of the steam drum in the water tube type of boiler, in the rear head of the return tubular boiler, above the upper row of tubes, and in the crown sheet of the locomotive and vertical types of boilers. They should be kept free from accumulations of scale, otherwise this may become strong enough to hold the pressure and prevent warning of the danger, even after the plug has melted out. On the other hand, a layer of sediment may prevent the water from absorbing the heat as it should, and may thus cause the plug to fuse when there is absolutely no danger. Inspectors are required to renew these plugs at each annual inspection; for the melting point of the fusible metal may change under the effects of the heat and the water, so as to make an old plug an unreliable device. Furthermore, it is not possible to test the fusible plug so as to determine whether it is at all times in condition to give the alarm in case low water should occur.

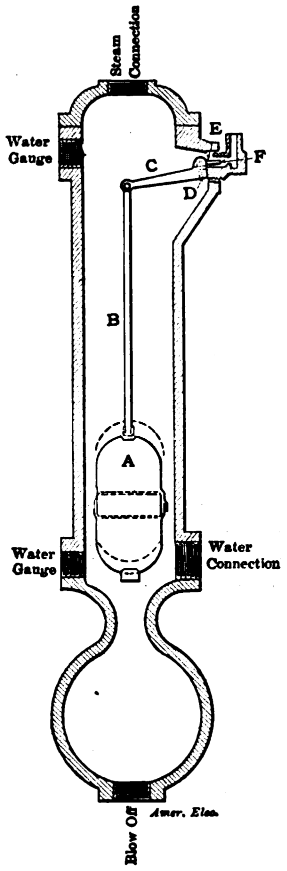

FIG. 5.

In view of these objections and difficulties, a class of safety devices known as low water alarms has been placed upon the market. The principles of construction and operation vary largely, but the alarm in Fig. 5 represents one of the most common forms of this apparatus. It consists of a cast-iron water column within which is placed an air and water-tight float, *A*, rigidly attached to a vertical rod, *B*, the latter being in turn connected to a bell-crank lever, *C*, pivoted at *D*. The short arm of the lever is attached to a tapering plug valve, *E*, which controls the opening, *F*, leading to a small steam whistle. When the water is at its normal level in the column, the buoyancy of the float, *A*, pushes the long arm of the lever, *C*, upward, and forces the plug, *E*, to its seat, closing the exit, *F*. Should the water level fall to or below the danger point, the float also descends and in so doing opens the valve, *E*, permitting live steam to escape through *F* and sound the whistle, thus calling the attention of the fireman or water tender to the fact that the water level is low. The whistle will continue to blow until the pump or the injector has been started and the boiler filled to or near its normal level.

The alarm just described, however, can give warning only in case of low water. There is danger also in carrying too high a level, since this may cause water to be carried over into the engine cylinder in such amount as to wreck the engine. The alarm shown in Fig. 6 is a combined high and low-water alarm. It contains two floats, each of which, through a connecting rod and lever, controls a valve leading to the whistle. When at normal level, the water is at such height as to maintain the float, *A*, in the position indicated by the dotted lines, and the float, *B*, in the position indicated by the full lines. If the water rises, the float, *B*, also rises and when the level reaches the top gauge cock the float, *B*, opens the valve, *C*, and gives the alarm. On the contrary, if the level falls much below the lower gauge cock, the float, *A*, falls to the position denoted by solid lines and opens the valve, *D*, also sounding the whistle. To keep the whistle silent, therefore, it is necessary to maintain a fairly constant water level in the boiler. It will be observed that each of these columns is provided with a spherical sediment chamber, which can be blown out by a blow-off valve attached at the bottom of the column. By opening the blow-off valve, the water level in the column may be lowered sufficiently to test the action of the low-water float, and this test can be made at any time.

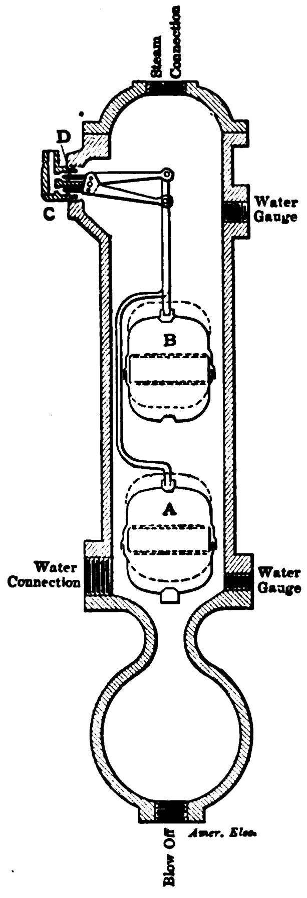

FIG. 6.

It is not necessary to have two floats for the purpose of registering both high and low water. These objects may be attained by the use of a single float, as in Fig. 7. In this type, there is a passage through the center of the float, *A*, allowing it to move up or down on the rod, *B*, according to the variation of the level. The rod is fitted with two nuts, *C* and *D*, one at each end, which may be screwed closer or farther apart, thus regulating the allowable limits between which the water level may fluctuate without sounding the alarm. The counterweight, *E*, pivoted at *F*, balances the weight of the rod, *B*, and its lever, *G*. The latter is pivoted at *H*. When the water level gets too high, the float strikes the nut, *D*, pushes the rod, *B*, upward and causes the lever, *G*, to fulcrum against the point *L*, which pulls the joint, *H*, and the plug, *M*, downward, admitting steam to the whistle through the ports, *N N*. If the level falls too low, the float, *A*, strikes the nut, *C*, pulling the lever, *G*, downward, so that its shorter end fulcrums at *Q*. Further downward motion of the rod, *B*, then opens the valve and sounds the whistle, as before. A valuable feature of this alarm is that all working parts are connected to the removable head, *R*, so that there is little difficulty in removing these parts for adjustment or repair. Another single-float alarm for both high and low water is illustrated by Fig. 8. In this case the float is rigidly attached to the rod, which moves up and down through a slot in the end of the valve lever, *A*. The adjustable collar, *B*, regulates the variation in water level through which the alarm will not sound. It will be seen that no matter whether the lever *A* be depressed or raised, it will raise the plug, *C*, since this lever may fulcrum at either edge of the block, *D*. Still another type of high and lower-water alarm is shown in Fig. 9. Instead of attaching the float to a rod, it is

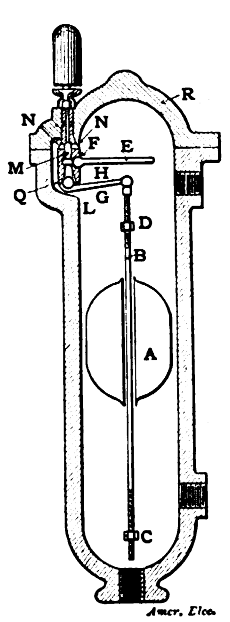

FIG. 7.

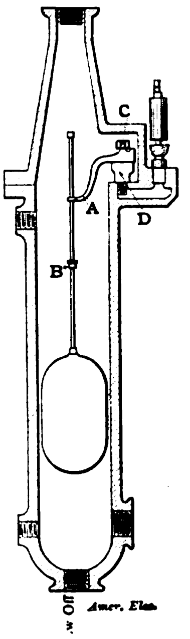

FIG. 8.

made spherical and is perfectly free of all connection with the remainder of the apparatus, floating at the surface of the water. The spherical shape offers the greatest resistance to the pressure from without. When the water level rises too high, the float presses against the curved diaphragm *A* attached to the lever *B* by the rod *C*. This motion of the lever opens the valve *D* and gives the alarm. A ring, *E*, also attached to the valve, *D*, by a rod, *F*, catches the float when the water level falls too low and is depressed by the weight of the sphere, thus opening the whistle valve. All of the working parts are fixed to the removable head.

The alarms previously described depend upon the buoyancy of hollow cylindrical or spherical floats for their action. Considerable difficulty and annoyance have been experienced by the leakage of these floats, and also by their collapse under the high pressures now carried in many plants. The introduction of seamless floats has prevented leakage trouble, but distortion due to pressure is not so easily overcome. A style of low-water alarm which obviates both of these difficulties is illustrated by Fig. 10. The whistle valve, *A*, is jointed to the lever, *B*, which is fulcrumed at *C*. To the left of the fulcrum a cast-iron weight, *D*, is hung from the lever, and at the extreme right is suspended a hollow cylinder, *E*, by the rod, *F*. This cylinder is perforated, near the top, by several holes, through which it is filled by the water in which it is immersed. So long as the water level remains above the lower danger line, the alarm is silent, as the moment of the weight, *D*, about the fulcrum, *C*, is greater than that of the submerged cylinder, *E*, thus keeping the valve, *A*, closed. Should the water level fall dangerously low, the cylinder, *E*, will no longer be wholly submerged, and its weight, together with the weight of the water it contains, will overbalance the effect of the counterweight, *D*, and open the whistle valve, *A*. The stop, *G*, prevents the descent of the cylinder, *E*, beyond a point necessary to open the valve, *A*, fully. The advantage of having all internal mechanism attached to the removable cover plate is observed in this alarm also.

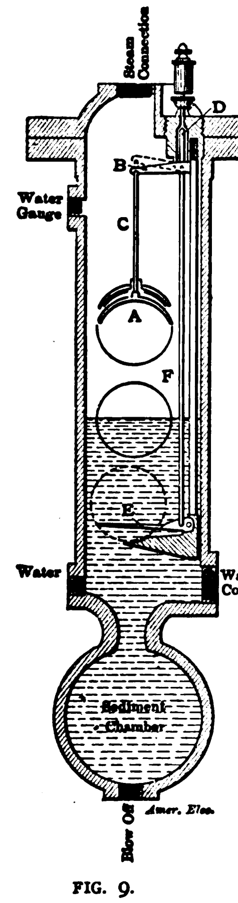

FIG. 9.

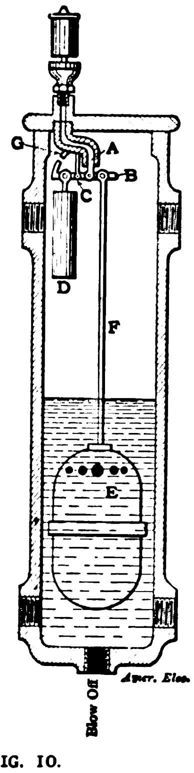

FIG. 10.

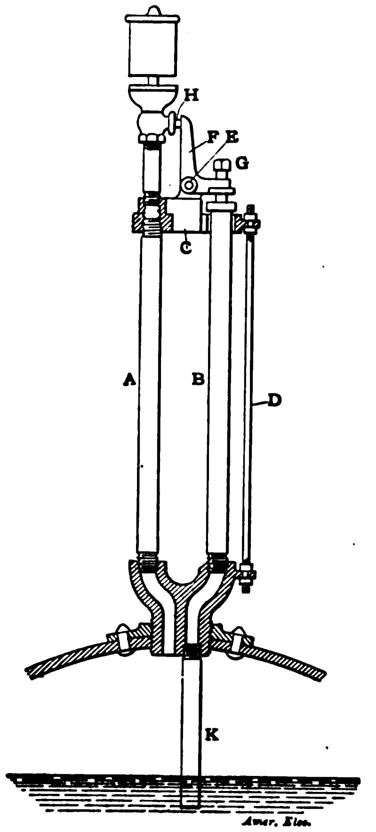

FIG. 11.

The use of two bars of different metals, having different coefficients of expansion, to operate various devices, has become quite common, and in Fig. 11 is illustrated a low-water alarm making use of the difference of expansion of two metals under the effect of heat. Two pipes, *A* and *B*, are connected to a cast-iron Y, which is screwed into the boiler shell above the water level. The pipe, *A*, which is of wrought-iron, serves to lead steam from the steam space to the whistle valve, and is rigidly attached to the cast-iron yoke, *C*. The pipe, *B*, of copper, has its lower end firmly screwed into the Y fitting. Its upper end is closed by a cap, and is free to move vertically up and down through a hole in the yoke, *C*. A tie rod, *D*, with adjusting nuts, serves to hold the yoke rigidly in place. Fastened to the yoke, *C*, is a short lug holding a pin, *E*, on which the bell-crank lever, *F*, is pivoted. The short end of this lever carries a set-screw, *G*, which rests against the cap on the pipe, *B*. The long end of the lever touches the stem, *H*, of the whistle valve. A pipe, *K*, whose lower end is at the lowest safe water level is inserted into the opening of the Y, which leads to the copper pipe, *B*. So long as the water in the boiler is above the danger limit, the end of the pipe, *K*, remains submerged, and the boiler pressure forces a column of water up into the pipe, *B*. Owing to the large radiating surface of this pipe, the water is comparatively cool. Should the water level fall below the end of the pipe, *K*, however, the water in the pipe, *B*, runs out, and the space is filled with live steam. The difference in temperature between the water formerly filling the pipe and the steam causes the pipe, *B*, to expand, pressing the set-screw, *G*, upward. This motion being transmitted to the short end of the lever, *F*, the longer end is forced against the stem, *H*, opening the valve and permitting the alarm to sound. The linear expansion of copper is slightly more than 1-10,000 of an inch per foot for each Fahrenheit degree increase of temperature. Consequently it may be readily seen that the movement of the lever will be very small, and that to keep the alarm in proper working order, it will be necessary to maintain very accurate adjustments of the parts.

The alarm shown in Fig. 12 makes use of the expansion of air as an agent by which to give warning of low water. The device is screwed into the water column in the place of the lower gauge cock, so that the chamber, *A*, is filled with water when the water level is normal, and this water is comparatively cool. Separated from the chamber, *A*, by a thin partition, *B*, is a closed chamber, *C*, one side of which is formed by the flat circular diaphragm, *D*. The chamber, *C*, is filled with air. When the water level becomes too low, steam enters the chamber, *A*. Its heat being transmitted through the wall, *B*, the air in chamber *C* expands, forcing the diaphragm outward, carrying the plug, *E*, with it, until it meets the end of the screw, *F*. This contact closes an electric circuit, and rings a bell which may be placed at any desired point. When sufficient water has been pumped in to raise the water level, the water in chamber *A* cools down, and the spring, *G*, returns the plug, *E*, to its former position.

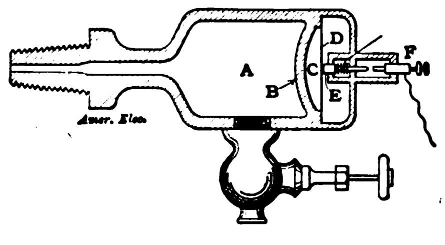

FIG. 12.

There are many advantages to be derived from the use of a good water alarm. It gives undeniable evidence of inattention or carelessness on the part of the boiler attendants, and since it can be kept silent only by the maintenance of a proper water level, the device encourages uniformity of working conditions. It has been argued that after a short period of working with automatic alarms, the firemen grow to depend wholly upon these attachments as a guide in feeding the boilers. While not altogether objectionable, this practice forms a strong argument in favor of alarms of absolute reliability at all times. Additional advantages of a steady water level are to be found in less leakage of tubes or seams due to unequal expansion, less danger of burned plates, and dryer steam.

WIRING FOR FACTORIES, MILLS, ETC.

BY ARTHUR B. WEEKS.

Before beginning any wiring work, it is best to go over the course thoroughly to get the most direct route, eliminating all the turns possible, and saving all the splicing practicable. The run having been arranged, the cleats or insulators are located. Porcelain cleats can be used to advantage on cable as large as 300,000 circular mils and by properly spacing the cleats very little sag in the line will result. For cables larger than 300,000 circular mils special cleat insulators are used. At turns the insulators should be neatly arranged, and in open work with joists, 2 x 4's will be required on which to fasten the insulators. Where mill construction is employed, none need be used.

When boring through mill floor construction, where nails are hit promiscuously, it is best to bore with either a rachet or pneumatic drill. Much time will thereby be saved and many "bits" spared from being spoiled by nails. In crossing other wires, circular loom or porcelain tubes should be used, the loom or flexduct being preferable owing to the fragile nature of porcelain.

It is generally known that in running wires through walls or partitions porcelain tubes are required. In some cases tape will be necessary for holding a tube in place. Inside wiring should always be rubber core, and in some special places, fire and weather-proof. When passing into cellars and subways or under engine room floors and among steam and water pipes great care is required in running wires. As much clearance as possible should be allowed between pipes and wires, and no sag in the wires should be permitted. Pipes carrying oils and gasoline are sometimes run in tunnels built for them, and since nothing but an incandescent lamp can be used in such places, it is best to cut them in directly on the line, using no fuses at the lamp, but fusing the main outside the tunnel, and controlling all the lamps by a switch. A vapor-proof globe is the safest made. Too much care in this respect cannot be used, and where power wires tap a feeder in so dangerous a place as this, it is not wise to change the size of the wire; but the same size of wire as the feeder should be used to a point out of the danger district, where fuse blocks may be located.

In damp places porcelain weather-proof sockets should be used, and if there are inflammable gases, vapor-proof globes should be employed. One sometimes finds brass lamp sockets used in such places due to ignorance or gross carelessness. A well-paid electrician can save many times his salary in the course of a year, by taking care of just such things. A fire can be easily started from a blown fuse in a tunnel containing gases, or in one where gases are liable to escape.

Iron conduit can be frequently used to advantage through tunnels; and outlet boxes employed where there are taps. In running two-phase, alternate-current power lines, however, do not run a conduit for each wire; but insert the two wires of one phase in an iron conduit, using another conduit for the wires of the other phase. The underwriters may allow all four wires in one conduit; but the former practice will usually be found better.

Many ingenious methods are in vogue for securing wire supports through tunnels and in fire-proof buildings across and parallel to the girders. One thing should be uppermost in the wireman's mind when doing such work, and that is to secure perfect insulation. There are other important features much to be desired, such as neatness, symmetry and permanency; much wiring being done with the proverbial "lick and a promise," and never touched again. A joint is often made, and, no tape being at hand, is left for the indefinite future; a hurry job for a splice where a wire has broken calls for slipping the wire off an insulator to provide the requisite slack, and, instead of being properly attended to, the wire is left unsupported. At a furnace, the flames may have bared the conductors, and these are left for the future. A loose wire in the binding post of a motor has perhaps arced until a repair job is needed to put it in order; perhaps all it will get is a twist around the screws of the terminal. Loose screws in fuse blocks and blown fuses from poor contact often go unnoticed.

If changes in factories call for a change in wiring, the work should be made neat and permanent as soon as possible. Twenty feet or more of cable hanging loosely from a nail or hook on the wall, or over a peg on a post for a week or more, does not look business-like. In iron buildings for storing varnishes and oils, special care should be required, and no fuse whatever allowed at individual lamps. Vapor-proof globes should be used in all dangerous places, and porcelain weather-proof sockets in damp ones. Lights should be located so that when the lamp is carelessly left to swing, it will not strike against tanks, girders or wall, or else guards should be fitted for these sockets.

Wiring for outside work should be substantially done, especially if wires enter buildings at points where ice is liable to accumulate on them, or where falling ice strikes them. This is often overlooked, with the result that wires break or become grounded. The wires should be secured so that it will be impossible for them to be pulled against the iron work of a building. Special work is sometimes necessary. They should have a firm support inside the building and if they leave the building at an angle, a support is also necessary on the outside. It is sometimes more convenient and less expensive to run feeder wires on the outside of buildings instead of carrying the wires through from various rooms, making numerous turns to avoid shafts and belts and other obstructions.

To fasten wires along a brick wall, 2 x 4's can be fastened to the wall and the insulators fastened to these, or the wall can be plugged and malleable iron wall brackets fastened directly to the wall. Double petticoat glass insulators should be used for this work, and not porcelain knobs. Rubber core wire should not be used for outside work, as it is not intended for this work and is not durable. Outside work of this kind requires good weather-proof wire, and should the wiring be around boilers, blast furnaces, etc., where there is great heat, fire-proof as well as weather-proof wire will be needed.

While No. 14 wire might be amply large for use in these places, it is best to use No. 12 or even No. 10, since mechanical strength should be the first consideration. In work of this kind where there is no fire risk, taps for drop lights can be made with No. 14 fire and weather-proof wire directly, without fused rosettes. The lamps in the circuit, however, should be controlled by a switch, and the main fused. If the switch and cut-out block, or fused switch, are out doors, a convenient box can be made and secured to an iron column within reach of the ground. Arc lamps in the vicinity of blast furnaces should be raised and lowered by means of ¼-in. iron cable, and so located as to be least effected by heat and escaping gases.

Lessons in Practical Electricity

THE TRANSFORMER.

As explained in an early lesson, the passage of a current through a wire coiled about a bar of iron or steel will magnetize the bar. If the magnetizing current be alternating, the magnetism in the bar will be alternating: that is, the polarity of the ends will alternate in accord with the alternations of the magnetizing current. As the magnetizing current rises from zero to maximum in one direction, the magnetic flux in the bar rises from zero to maximum in the corresponding direction, and as the current dies away to zero again, the flux dies away. Now, if a second coil be wound about the bar, the rising, falling, reversing, etc., of the magnetic flux will induce in this second coil an e.m.f. which will rise, fall, reverse and rise, fall, and so on, in response to the variations of the flux. The elementary form of such an arrangement is indicated in Fig. 1, where a round iron bar is shown wound with a primary coil, *P*, which is supplied with current from an alternating-current generator, and a secondary coil, *S*, in which an e.m.f. is in-

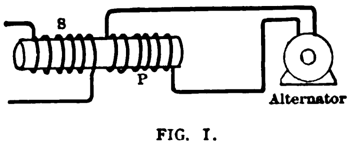

FIG. 1.

duced by the varying magnetic flux produced by the current in the primary coil.

In an arrangement such as that shown in Fig. 1, the magnetic flux would have to complete its circuit through air from pole to pole of the bar, and the flux produced by a given magnetizing current would be relatively small on account of the high reluctance of the air path. With a continuous core, as indicated in Fig. 2, the flux would be much greater, and a given magnetizing current in the primary coil would produce a much higher e.m.f. in the secondary coil, the induced e.m.f. being exactly proportional to the flux strength, as in the case of a dynamo. If the coils were arranged as indicated in Fig. 2, however, part of the magnetic flux produced by the primary coil would pass around the coil through the air instead of the other leg of the core, as indicated roughly by the dotted lines in Fig. 3, and these would not only be wasted so far as inducing secondary e.m.f. is concerned, but they would increase the self-induction of the primary coil and thereby reduce its activity. In order to reduce this magnetic leakage to the smallest degree it is customary to wind one coil over the outside of the other, as shown in Fig. 4, so that practically all of the magnetic lines of force set up by the primary winding will "cut" across the convolutions of the secondary winding as they expand and collapse from and toward the center of the iron core. Even with this arrangement, there is a little leakage of magnetic lines through the insulating material between the two coils (represented by the heavy line in Fig. 3).

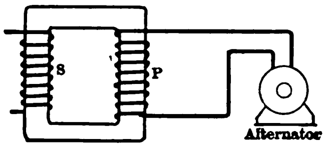

FIG. 2.

The relations between the primary winding, e.m.f. and current and the secondary winding, e.m.f. and current are roughly as follows:

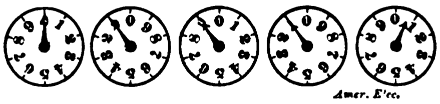
$$\frac{Pri\ e.m.f.}{Sec.\ e.m.f} = \frac{Pri.\ turns}{Sec.\ turns} = \frac{Sec.\ current}{Pri.\ current}$$

The expression $\frac{Pri.\ e.m.f.}{Sec.\ e.m.f.}$ is termed the transformer ratio, or ratio of transformation. It is some times convenient to represent it by a symbol, k_t. Then the relations between the windings, e.m.fs. and currents may be indicated very concisely by means of simple formulas, thus:

$$E \div k_t = e$$
$$N_t \div k_t = n_t$$
$$I \times k_t = i,$$

the capital letters representing primary e.m.f., number of turns and current while the small letters indicate corresponding secondary values. These formulas are only approximately accurate, for reasons that will be explained more fully in the next lesson. Reduced to plain English they mean: That the secondary e.m.f is approximately equal to the primary e.m.f. divided by the ratio of transformation; that the secondary current is approximately equal to the primary current multiplied by the ratio of transformation, and that the requisite number of secondary turns is approximately equal to the number of primary turns divided by the ratio of transformation.

The starting point, however, is the applied primary e.m.f.; this is always the first known quantity, and upon it depends the number of primary turns for a given transformer capacity. The size of the core, and consequently the magnetic flux, also affects the number of primary turns. The counter e.m.f, of the primary winding (due to self-induction) is so nearly the same as the applied e.m.f. at the primary terminals that the two may be considered equal for purposes of rough analysis. This e.m.f. is given by the equation



TRICKY METER READING.

$$E_t = 4.44\ f\ \Phi\ N_t \div 100{,}000{,}000$$

in which f is the frequency of the supply e.m.f. in cycles per second and Φ is the magnetic flux produced in the transformer core. The amount of magnetic flux in the core is limited, practically, by the size of the core cross-section. Hence, the size of core has a direct bearing upon the number of primary turns. The size of the primary conductor also has an important bearing upon the number of turns for the reason that the space occupied by the winding must bear some relation to the size of the core, and only so many turns of a given size of wire can be got into a given space. Since these are features of practical design, and do not affect fundamental operating principles, they will not be analyzed here.

The e.m.f. induced in the secondary winding by the magnetic flux is ascertained by exactly the same formula as the primary induced e.m.f., substituting primary values, thus:

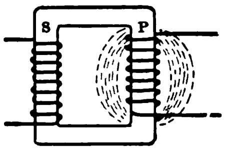


FIG. 3.

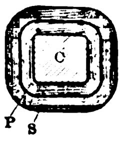

FIG. 4.

$$e_t = 4.44\ f\ \Phi\ n_t \div 100{,}000{,}000$$

from which it will be evident that the relations between the primary and secondary *induced* e.m.fs. and conductor turns are accurately given by the formulas which give approximately the relations between *terminal* e.m.fs. and turns. The relations between terminal and induced e.m.fs. will be explained in another lesson, along with other phenomena involved in transformer operation.

Letters on Practical Subjects

Mr. Bennett's Meter Reading.

To the Editor, American Electrician:

Referring to Mr. Bennett's tricky meter reading in the June number, I submit 91,000 as the reading, assuming that the right-hand dial is calibrated in hundreds (a complete revolution = 1000). Beginning at the right, the pointer is between 0 and 1 and therefore reads 0; the next pointer is at 1 and the middle pointer is at 9. The pointer of the dial next to the left appears to be at 1, but it cannot have reached that figure until its right-hand neighbor reaches *O*, so that it must be read *O* as the meter stands.

Canton, Pa. H. LEE CLARK.

[The same solution and explanation have been received from B. H. Barre, Bennettsville, S. C.; R. C. Barton, Alameda, Cal.; Wilfred S. Boult, Brooklyn, N. Y.; J. D. Cartin, Watertown, N. Y.; Uriah Davis, Chicago; C. F. DeRichmond, Ridgewood, N. J.; James B. Dillon, Louisville, Ky.; B. H. Elkins, South Windham, Me.; George A. Gould, Phillipsdale, R. I.; D. I. Gue, Chester, Iowa; C. S. Kaefle, Trenton Falls, N. Y.; Wilson A. McCown, Ladonia, Tex.; George Ocobock, Ovid, Mich.; Martin O'Connor, Milwaukee, Wis.; C. F. Richardson, West Minneapolis, Minn.; Albert H. Ryan, San Diego, Cal.; Philip C. Schools, Wardner, Idaho; Joseph E. Stenlake, Allentown, Pa., and A. V. Youens, Wilkinsburg, Pa.

The following readings, which are the same as Mr. Clark's except that the indication of the right-hand pointer is estimated, have also been received: 91,033 from W. M. Aiken, Bennington, Vt.; 91,050 from Arthur Barthels and Robert Young, of San Francisco (independently); 91,060 from J. P. Jones, Cedar Falls, Iowa, and Ralph Ryder, New York; 91,066 from Fred J. Ruffey, Rochester, N. Y., and L. A. Schultz, Craftonsville, Cal.; 91,075 from C. M. Green, Conneaut, Ohio.—EDITOR.]

◆

An Unusual Potential Wire Effect.

To the Editor, American Electrician:

We are operating a three-wire, 220-volt system with potential wires from the center of distribution back to the station voltmeter. Sometimes the voltage on one side of the neutral wire is higher at the center of distribution than it is at the station bus-bars: that is, the voltage between the neutral wire and one of the main wires is higher at the far end of the feeders than it is at the bus-bars. Can anyone explain why?

Canton, Pa. H. LEE CLARK.

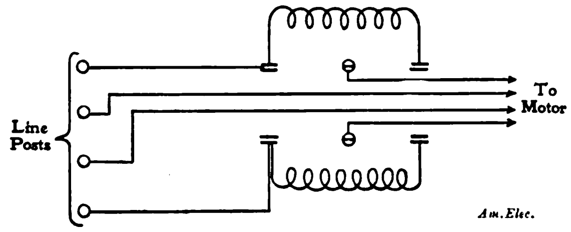
◆

An Emergency Induction Motor Starter.

To the Editor, American Electrician:

An autotransformer starting box used on

a 50-h.p., two-phase induction motor recently burned out, and as it was important that the motor should be kept in operation, I had recourse to the following simple expedient: Two pieces of No. 14 iron wire, each 100 feet long, were wound into spirals 4 inches in diameter and mounted on frames which were put into barrels and filled with water. The starting switch panel was then mounted on two timbers and located near the barrels, and the motor was connected to the improvised starter and the main line as shown by the accompanying sketch.



EMERGENCY INDUCTION MOTOR STARTER.

Although there is nothing new or original about this arrangement, it is described with the hope that it may be of interest to some readers of the AMERICAN ELECTRICIAN.

Mesa, Ariz. F. W. CERNY.

◆

A Commutator Trouble.

To the Editor, American Electrician:

The plant I am in charge of has two 45-kw., direct-current generators connected in the usual way to a three-wire system of distribution. The commutator of the dynamo on the positive side of the system gives trouble continuously by developing what seems to be a carbon burn extending around one-fourth of the commutator circumference, approximately. We have sandpapered the commutator, of course, a number of times; but after a couple of nights' running the blackening returns. I will appreciate any suggestions as to the cause of this trouble and the remedy for it.

Nogales, Ariz. V. P. MALONEY.

[Readers are invited to send to this office, for publication, suggestions concerning Mr. Maloney's commutator trouble. Such communications must be received here not later than July 15th.—EDITOR.]

◆

Those Needed Mirror Lamp Holders.

To the Editor, American Electrician:

In your June issue, under the head of "Some Things We Need," Mr. C. R. James calls attention to the need of a device whereby an incandescent light could be quickly and easily attached to each side of the mirror of a dresser. We have just this in our "Electrogrip." If Mr. James or any one else interested will send their address we will be pleased to send, without any cost to them, a sample of the device.

APPLIED DEVICE COMPANY.

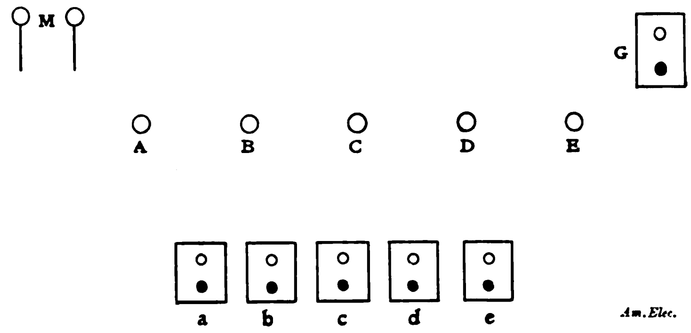
Problem in Switch Connections.

To the Editor, American Electrician:

A problem in incandescent wiring came up in my work some time ago and I submit it for consideration by the readers of the AMERICAN ELECTRICIAN. Five outlets, located respectively in the kitchen, dining-room, parlor, hall and veranda of a residence, were to be wired for control individually by means of five flush push-button switches and collectively by means of a similar switch located in a bedroom upstairs. In the accompanying diagram, the outlets are represented at *A, B, C, D* and *E,* the corresponding individual switches by *a, b, c, d* and *e,* the gang switch by *g* and the main line entrance by *M.* The object, of course, is to make the connections with the least quantity of wire.



PROBLEM IN SWITCH CONNECTIONS

SAM L. LAUGHLIN.

Guelph, Ontario, Canada.

[Solutions for publication must reach this office not later than July 15th.—EDITOR.]

◆

Mr. Lincoln's Problem in Motor Circuits.

To the Editor, American Electrician:

The enclosed diagram (Fig. 1) is submitted as a solution of Mr. Lincoln's problem published last month. The two motors are connected to and disconnected from the supply circuits by means of a four-pole, double-throw switch, and reversed individually by means of the double-throw, double-pole switches *R1* and *R2.* When the four-pole switch is closed upward, the two motors are connected to the 110-volt circuit in parallel; when it is thrown downward, they are connected in series to the 220-volt circuit. The four-pole switch may readily be obtained by mounting two double-pole switches side by side and bolting a hard fibre bar across the two cross-bars of the switches, or substituting one long bar for the two shorter ones on the ends of the switch's blades. The two reversing switches, it may be noticed, are so connected to the motors and the starting boxes are connected in circuit in such a way, that no separate main switch is required for each motor; the leads from the reverse switch to the four-pole switch would be fused, of course, and each motor may be controlled by its reversing switch when the motors are on the 110-volt circuit. When they are on the 220-volt circuit, they cannot be controlled independently, of course, because they are in series.

Alameda, Cal. R. C. BARTON.

[C. E. Bryson, Chicago, and Martin O'Connor, Milwaukee, sent in solutions exactly like Mr. Barton's except that no starting boxes were shown on their diagrams. C. H. Pool, New York, sent a solution like the above except that no starting boxes were shown and the field and armature of each motor were transposed; that is, the armatures were connected to the middle posts of the reversing switches and the fields to the jaws.—EDITOR.]

To the Editor, American Electrician:

The enclosed diagram (Fig. 2) is submitted as a solution of Mr. Lincoln's problem. The motors are provided with individual reversing switches of the double-pole, double-throw type and are connected to either the 110-volt or the 220-volt circuit by means of a four-pole, double-throw knife switch. The motors should, of course, be protected by fuses; I omitted these because they have no bearing on the problem as it was stated.

Barre, Vt. HAZEN CLARK.

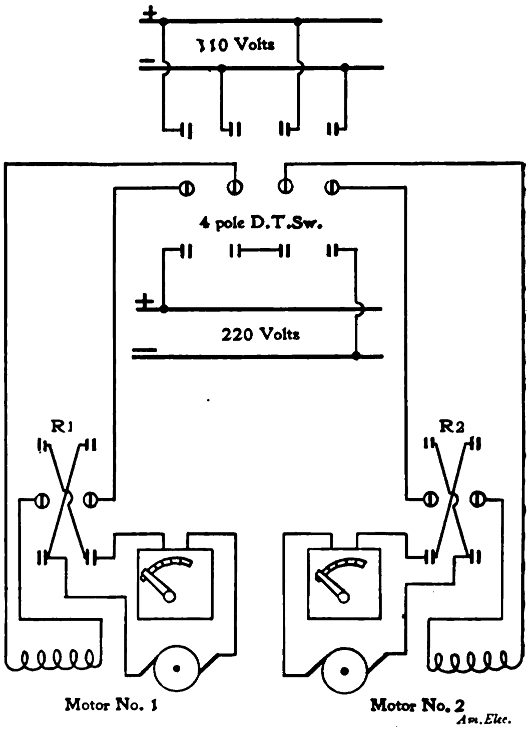


FIG. 1.—MR. BARTON'S SOLUTION.

To the Editor, American Electrician:

The accompanying diagram (Fig. 3) is one solution of Mr. Lincoln's problem in motor connections. Each motor armature is connected to an ordinary two-pole, double-throw, knife-blade switch for reversing; the free terminals of the field magnet windings are connected permanently together and to one post of a three-pole, double-throw switch, and the free posts of the reversing switches are connected to the other two posts of the triple-pole switch. Throwing the handle of the latter to the left puts the two motors in parallel on the 110-volt circuit; throwing it to the right puts them in series on the 220-volt circuit with the current reversed through motor *A*. This reversal does not affect the direction of rotation because both the field and armature are reversed in polarity. The motors should be fused individually, of course, to protect them when in parallel; the fuses would preferably be inserted in the two leads from the reversing switches to the main switch and in the two leads from the field magnet windings to the junction between them, but a three-pole fuse block might be used in the leads from the main switch posts by making the middle fuse equal to both the other two together. Each motor is provided with a starting box, *S*, which is put in the armature circuit in order to reduce the number of parts remaining "alive" when one or both of the reversing switches are open and the main switch closed. It is obvious that two motors of this type cannot be operated satisfactorily in series unless their loads are practically equal, but as nothing was said in the stated problem about this, I have not considered it in the submitted solution.

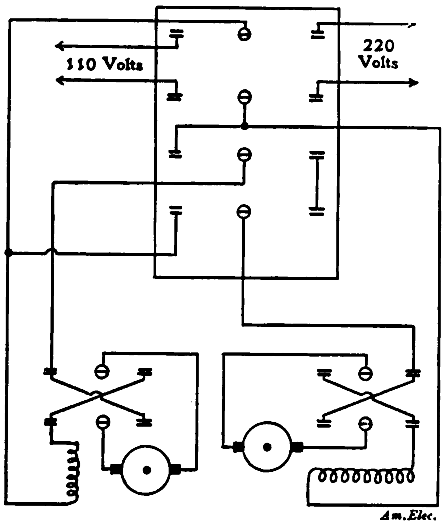

FIG. 2.—MR. CLARK'S SOLUTION.

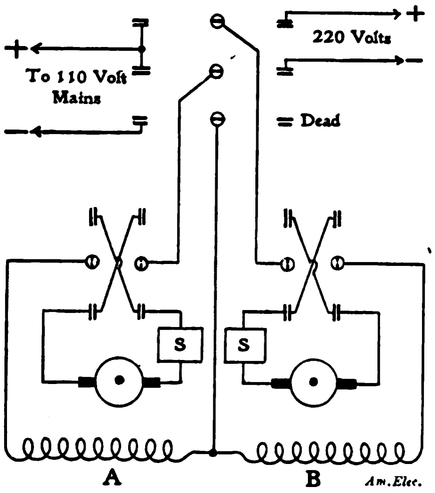

FIG. 3.—MR. MALCOLM'S SOLUTION.

GEORGE W. MALCOLM.

Brooklyn, N. Y.

[Richard Gessner, Oak Park, Ill., and Frank F. Redding, New York, sent in solutions like Fig. 3 except that the starting boxes were connected in the field circuits instead of the armature circuits; that is, in that part of the motor circuit between the reversing switch and the junction between the fields.

Charles B. Smeeth, Ironwood, Mich., sent in a diagram like Fig. 3 except that no starting boxes were included.—EDITOR.]

To the Editor, American Electrician:

I enclose herewith a solution of Mr. Lincoln's problem in motor connections (Fig. 4). The statement of the problem does not specify whether Mr. Lincoln already had reversing controllers for the motors or not, so I have assumed that they had only plain starting boxes. Two double-throw knife switches are therefore shown in the diagram for reversing the motors; the triple-pole, double-throw switch connects them properly to either of the supply circuits.

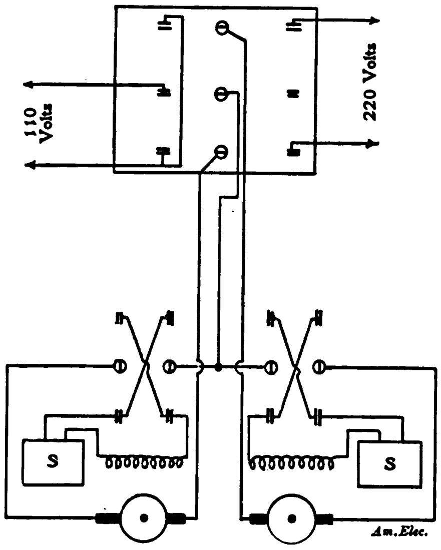

FIG. 5.—MR. SIEGEL'S SOLUTION.

As the system is simple, a detailed explanation is not necessary.

H. LEVAQUE.

Atlanta, Ga.

[Vernon R. Marshall, Chicago, Ill., sent in the same solution as Fig. 4, except that no starting boxes were shown.—EDITOR.]

To the Editor, American Electrician:

Enclosed you will find a solution of Mr. E. S. Lincoln's problem in motor connections. The diagram (Fig. 5) is practically self-explanatory; only three switches are used: one triple-pole and two double-pole, all of them double-throw.

C. R. SIEGEL.

Washington, D. C.

[W. H. Middleton, Jr., Princes Bay, N. Y., sent in a solution identical with this excepting that starting boxes were not shown.—EDITOR.]

To the Editor, American Electrician:

I send herewith a diagram (Fig. 6) as a solution of Mr. Lincoln's problem in motor connections. A four-pole, double-throw switch is used to connect the motors to either the 110-volt or the 220-volt circuit, and a double-pole, double-throw switch to reverse the two machines. A single starting box, *S B*, is used to start the two motors together; they must necessarily be thus started when in series on the 220-volt circuit, and if there is no objection to this arrangement there can be none to simultaneous starting on the 110-volt circuit. It is assumed, of course, that the motors will be properly protected by fuses; the arrangement of these is not a part of the problem, however, so I have not shown them in the diagram.

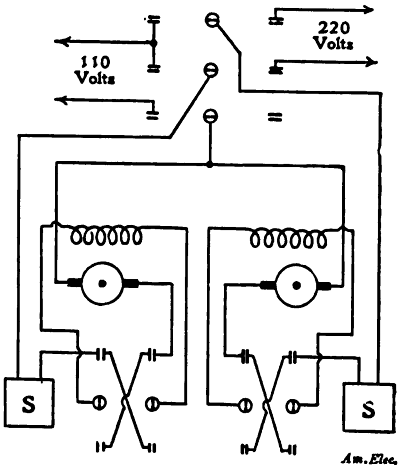

FIG. 4.—MR. LE VAQUE'S SOLUTION.

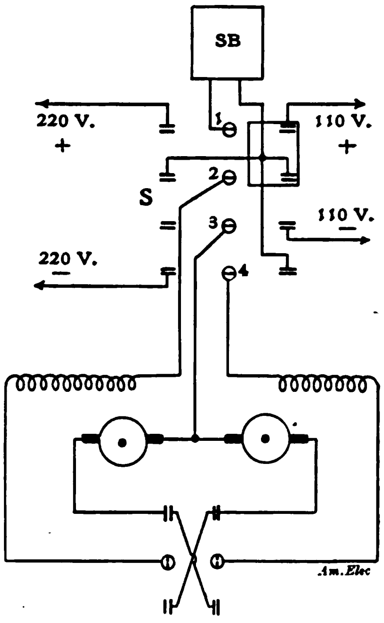

FIG. 6.—MR. MARSHALL'S SOLUTION.

JOHN J. MARSHALL.

San Francisco, Cal.

[The same solution was sent in by Jerome B. Wittkoski, Grand Rapids, Mich.—EDITOR.]

Queries and Answers

IMPORTANT.—No attention will be given to any inquiry which does not give the full name and address of the inquirer.

Which is regarded the standard primary voltage for central stations of moderate size and distribution area, 1000 to 1050 volts or 2000 to 2100 volts? N. B. U.

2000 to 2300 volts.

Where can I obtain castings for the voltmeter or ammeter described in the December, 1903, number of the AMERICAN ELECTRICIAN? D. S.

From Parsell & Weed, 129 West Thirty-first Street, New York.

Upon applying to the purification of beer a process for sterilizing water electrically, the fuses in the electrical circuit blow out frequently. What is the cause, and how can it be overcome? P. H.

The cause is too little resistance in the circuit; insert some resistance coils or else use heavier fuses.

Please explain the action of the Lincoln synchronizer. W. R.

This instrument, its principle and operation, were fully described in our November, 1901, number. Space limitations prevent its description in this department, and we do not reprint any matter in the other pages.

What is the outside diameter of a gear having 5 inches pitch diameter, 60 teeth and 12 pitch; also of a gear of half the pitch diameter and number of teeth, same pitch? H. M.

Outside diameter = pitch diameter + $\frac{2}{\text{pitch}}$; consequently the gears are 5.1666 ins. and 2.666 ins. outside diameter, respectively.

If a person should stand on wet ground and touch the blades of a knife-blade switch with a piece of metal held in the bare fingers, the switch being in a "live" 110-volt circuit absolutely free from grounds, would the person receive a shock? J. H. G.

No. There is no such thing as absolute insulation, however, so that such an experiment would not be safe with a circuit of high potential, such as 2000 volts alternating or 5000 volts direct current (arc light).

What is the advantage of grounding the secondary circuit of a transformer? A. C. L.

If the circuit is grounded on one side, the maximum difference of potential that can occur between the line and the ground is equal to the secondary voltage; if the transformers are grounded at the middle points of their secondary windings, the maximum possible potential difference between the secondary line and ground is one-half the secondary voltage. Crosses or leaks between the primary and secondary windings of the transformer, then, cannot cause dangerous potentials between the secondary line and ground.

What feature of engine construction or operation determines whether it is a high-pressure or a low-pressure engine? (2) What determines the identity of the high and low pressure cylinders of a compound engine? (3) Is a condensing engine necessarily a low-pressure engine? W. R. McD.

The pressure at which steam is delivered to the engine. The term is empirical; an engine taking steam at any pressure above 60 pounds is a high-pressure engine, whether the initial pressure be 90 pounds or 200. Low-pressure engines are not generally built now. (2) The pressure of the admitted steam; hence the cylinder taking steam first is the high-pressure cylinder. (3) No; but a low-presure engine is necessarily a condensing engine, because the exhaust pressure is not high enough to overcome the back pressure of the atmosphere.

What is a link motion on a steam engine? (2) Is there in regular operation an engine having electrically-operated valves? (3) Is there in regular operation an engine having an electrically-operated governor? (4) What is the usual speed variation between no load and full load for engines driving electric generators? T. K. D.

An arrangement of links and a motion transmission by means of which the engine valve may be operated by either of two eccentrics, one for the operation of the engine in one direction and the other for running in the opposite direction. Every American locomotive is fitted with such an arrangement. (2) Not to our knowledge. (3) Not to our knowledge; but there are many engines equipped with automatic governors which are adjusted by means of electrical mechanism to give the proper shaft speed. (4) From 1 per cent to 2 per cent, according to the buyer's requirements or the designer's judgment.

In Miller's "American Telephone Practice" the author says, referring to tests for line insulation resistance, that the insulation resistance per mile of circuit is equal to the total insulation resistance of the line *multiplied* by the length in miles; should it not read "divided" by the length? W. M. L.

No. The leakage paths through the insulation between the conductor and the supports are in parallel; consequently their joint resistance is equal to the individual resistances divided by the number of leakage paths, or the resistance of one path is equal to the joint resistance multiplied by the number of paths, assuming all the paths to have equal resistances, which is the only practical basis. The longer the line, the more leakage paths there will be, and consequently the lower will be the total insulation resistance. Mr. Miller's statement is therefore correct, on the assumption that the insulation is of the same quality everywhere along the line.

Please give a short formula for determining the resistance of a ground by means of a voltmeter. F. W. W.

No formula is generally applicable. The resistance of leakage paths between the conductors and frame of a dynamo may be determined by the formula

$$R_i = \left(\frac{E}{v} - 1\right) R,$$

in which E is the e.m.f. at the brushes of the machine, v is the indication of the voltmeter when connected to one brush and the frame, and R is the resistance of the voltmeter from terminal to terminal. The insulation resistance of an entire installation may be measured in the same way, E being the e.m.f. across the mains and v the lower of two voltmeter readings obtained with the instrument connected between a good solid "ground" and first one side and then the other of the circuit. The measurement of the resistance of an accidental "ground" on a circuit depends on local conditions.

Is it good practice to supply incandescent lamps and motors from the same circuit? (2) What system of wiring is best for incandescent lighting at 240 volts? (3) Is a No. 3 wire large enough to carry current 100 feet to two 25-h.p. 240-volt motors, allowing 3% drop in the line? (4) What is the best method of making connections between a travelling crane and the supply line? G. S. D.

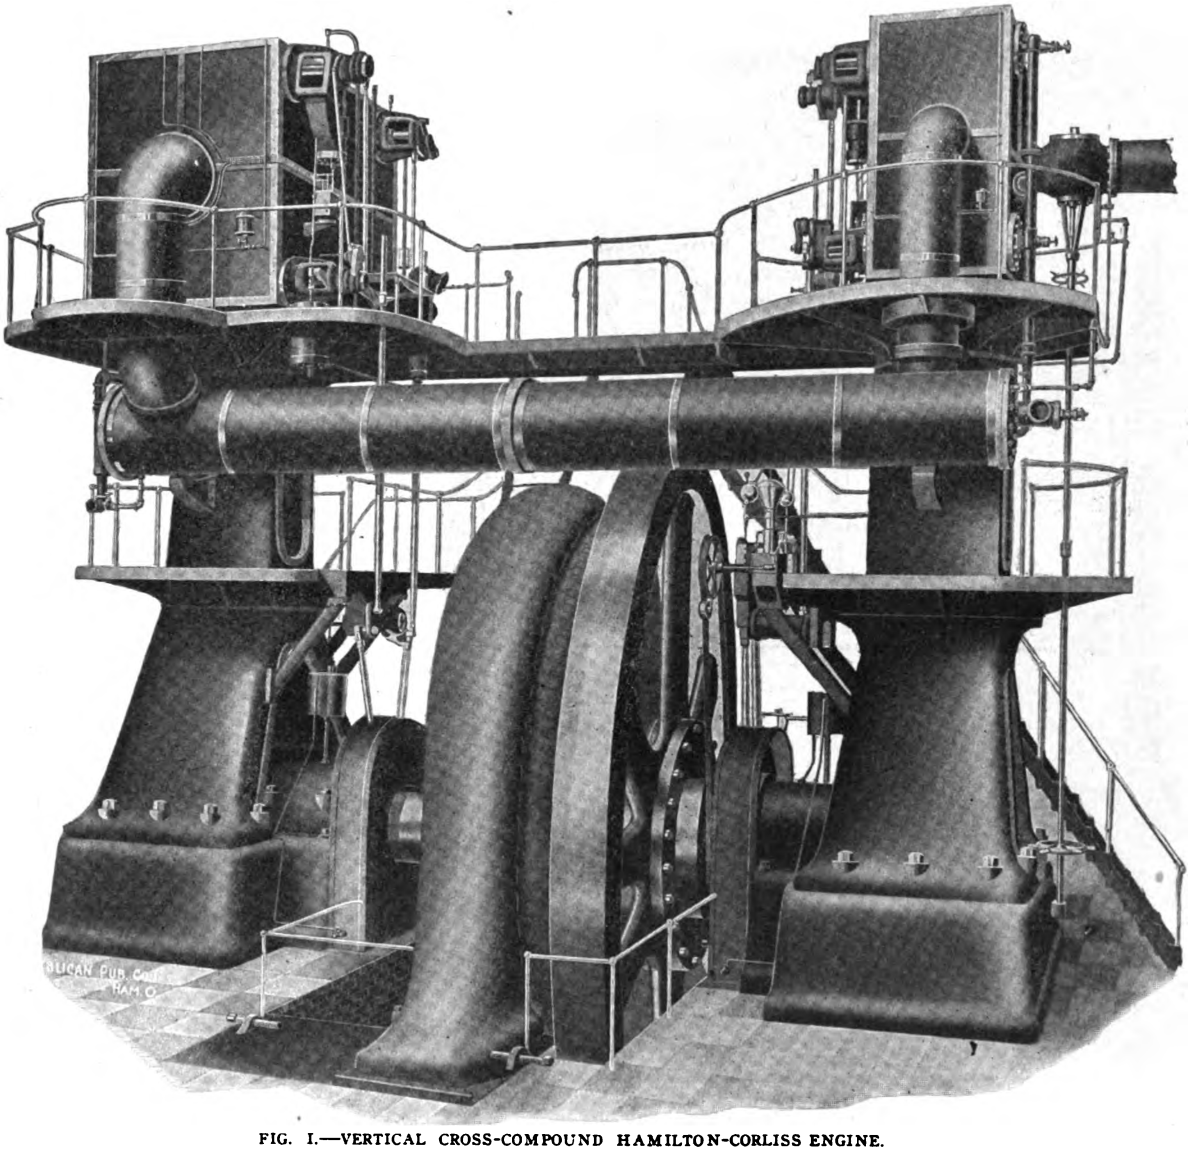
It depends on local conditions. If the supply conductors are of sufficiently large cross-section to prevent objectionable fluctuation in voltage when the motors are thrown in and out of circuit, it is permissible to supply lamps from the same circuit. Generally speaking, it pays to run separate circuits rather than to use a common circuit with conductors large enough to avoid serious fluctuations. (2) There is no "best" system. Usually it is preferable to use the three-wire system, 120 volts on each side of the neutral, with a motor balancer to equalize the voltages. (3) Yes, so far as the drop alone is concerned, but it is not large enough to comply with the underwriters' requirements. If the wire be rubber covered, if must be No. 0000 single or two No. 1 wires in parallel in each leg; if weatherproof, it must be either No. 0 single or two No. 4 wires in parallel. (4) By means of strap conductors mounted parallel to the crane travel and collector shoes mounted on the crane and sliding along the straps.

Can shunt-wound dynamos be operated in parallel without an equalizer? (2) How can shunt-wound and compound-wound dynamos be operated in parallel? (3) What classes of work are series, shunt and compound-wound motors used for? (4) If a motor driving a machine requiring the full power of the motor at normal speed be reduced to half speed by a regulating rheostat in the armature circuit, will the motor be overloaded? (5) If a 220-volt motor be operated at 190 volts, will not the speed be reduced and the armature current increased, as compared with what it would do on 220 volts? T. N. S.

It would be impossible to use an equalizer with them; the equalizer between dynamos operating in parallel is for the purpose of equalizing the current in the series field windings. (2) As though the compound-wound machine were shunt-wound; if there be more than one compound machine, all of that type must have an equalizing connection between them. (3) Series-wound motors are used where full load or over must be started from standstill and the speed may vary inversely with the load; shunt machines are used where practically constant speed is required and the load at starting is relatively small. Compound-wound motors are used where heavy loads must be started from standstill and the speed must not vary widely under varying loads; if practically constant speed is required, the series windings are short-circuited when the motor has almost reached normal speed. (4) Not unless the torque required by the driven machine is greater at half speed than it is at full speed. (5) Yes, if the load is exactly the same; the difference will not be important if the motor is well designed, however.

NEW HAMILTON-CORLISS STEAM ENGINE.

The Hooven, Owens, Rentschler Co., Hamilton, Ohio, has added to its well-known line of Corliss engines a vertical cross-compound type, the 2500-h.p. size of which is illustrated herewith. This engine is to be exhibited at the St. Louis Exposition, in conjunction with a National Electric Company alternator, the revolving member of which will be mounted directly on the engine shaft between the crank housings, as shown in Fig. 1. The alternator was described in our issue of May, 1904.



LICAN PUB. Co.
HAM. O.

FIG. I.—VERTICAL CROSS-COMPOUND HAMILTON-CORLISS ENGINE.

The bed-plate is of the box-section type, deep, massive and strongly webbed, with liberal bearing surface on the foundation. It is cast in one piece, and is carried around the crank at full height, forming a deep crank pit to retain oil. This base has easy lines and well-rounded corners. The main bearing portion is bored and faced to receive the bottom box, which is of the shell type, and so arranged that it can be removed by raising the shaft enough to remove the weight from the box. This box is arranged for water circulation.

The "A" frame is cast in two pieces, strongly webbed, and is planed and fitted together and bolted with reamed fitting turned steel bolts. Its lower portion is of the box, or rectangular section, which gradually changes to a circular section as it reaches the top, giving pleasing, but strong lines. The openings on the sides are especially designed to receive oil shields which entirely enclose this part of the engine. The guide barrel is circular in form, slightly flattened on the sides where the openings come, and the latter are designed for perfect fitting oil shields and doors. This portion of the frame is also strongly webbed. The guides are separated from the walls of the barrel by an air space, and are bored from a common center. The barrel is faced at both ends at the same setting, in order to obtain perfect alignment.

The cylinder sizes of the Exposition engine are: High-pressure cylinder, 34 ins. diameter; low-pressure cylinder, 68 ins. diameter; stroke, 54 ins.; speed, 83 r.p.m.; main bearings, 25 ins. diameter by 42 ins. long; shaft in wheel and generator, 30 ins. diameter; crank pin, 11 ins. diameter by 11 ins. long; wheel, 22 ft. diameter; weight, 120,000 lbs. The cylinders are made of close-grained charcoal iron, as hard as is practical to machine them. The exhaust chambers are separated from the cylinder walls by an air space. The arrangement is such that there is a 2-in. space between the cylinder walls and lagging for non-conducting covering. They are lagged with sheet steel with bright polished angle steel. The valves are located in the barrels to avoid the inconvenience of having to disconnect the valve gear when the heads are removed. The valves, however, have been placed in such a manner as to reduce the clearance to about the same as if they were placed in the heads by bringing the exhaust valves partly within the cylinder walls, although at no time do the valves enter the space swept by the piston, while the piston is allowed to sweep past the ports. The arrangement is different on the steam valve side. The ports on this side are so arranged that the incoming steam strikes the piston squarely on the end, thus preventing any side shock or pounding common to the vertical type of engine. Both steam and exhaust valves are double ported and have a very short travel. The valves are cored and made as light as possible.

The pistons are also cored and made as light as is consistent with the proper factor of safety. Each piston has a follower ring and one sectional ring, which is pressed out by spiral springs held in place by T-headed brass bolts. The pistons are forced on a taper and locked with a jam nut and keeper. The cross-head is of steel, with cast-iron slippers, lined with best phosphor babbitt, peined in, bored and scraped to fit. Each slipper has a wedge adjustment which is entirely independent, hence the position of the slipper is not changed by its movement. The slippers are fastened to the cross-head by several steel bolts, thus relieving the wedge bolts of any extra strain, and are so arranged that they can be easily removed. The piston rod is fastened to the cross-head by threads, jam nut and keeper. The connecting rod is of the solid end pattern, and is five and one-half cranks long, with wedge adjustment at either end, so arranged that in taking up the boxes the length of the rod and clearance spaces remains constant. The boxes are of bronze, babbitted, peined, bored and scraped to fit.

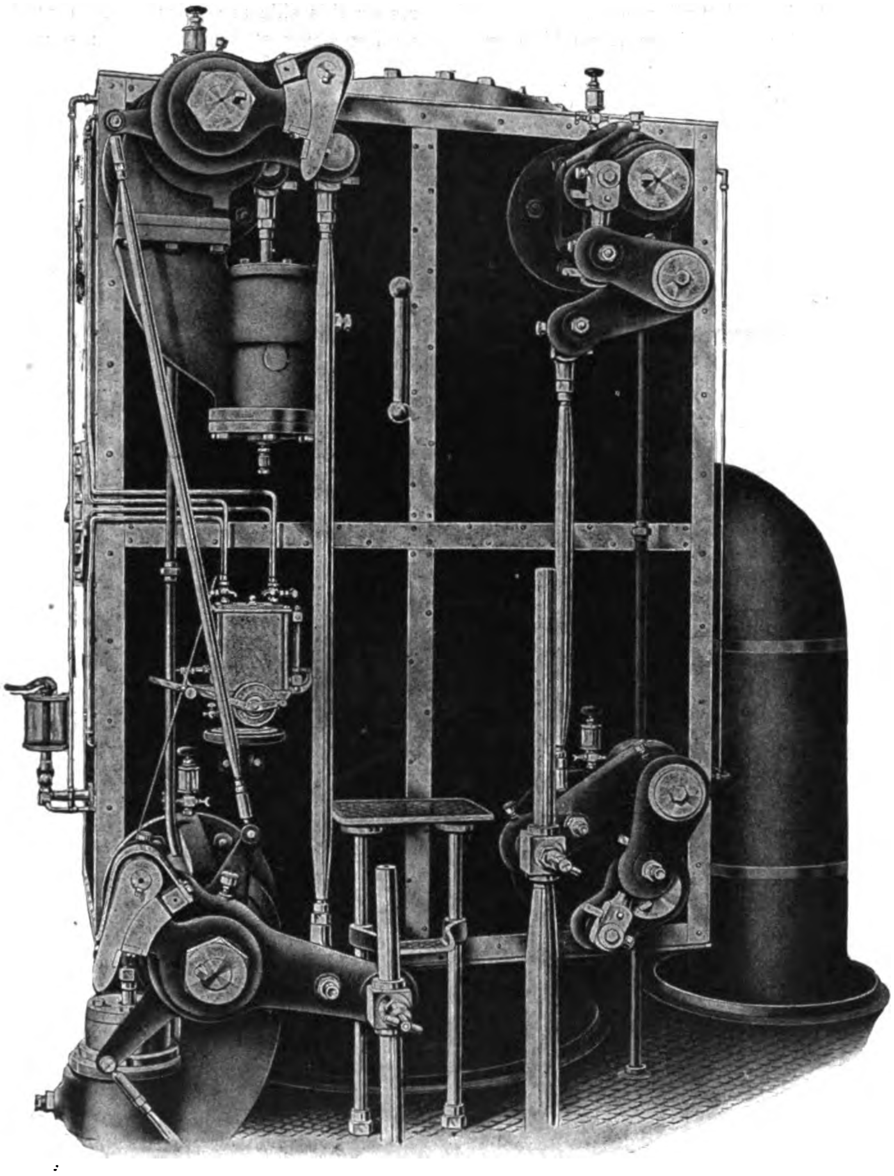


FIG. 2.—HIGH-PRESSURE VALVE GEAR.

The valve gear differs somewhat from the company's regular type. The steam and exhaust valves are actuated by separate eccentrics, direct, without wrist plates, as shown in Fig. 2 herewith. The necessary motion is obtained by the use of levers and links on each bonnet separately, thus greatly reducing the strains. The dash pots are hung from the bonnets and are close to the cylinder, making a very compact and self-contained arrangement. They are of the manufacturer's new noiseless pattern, with the weight of the moving parts greatly decreased, and are adapted for much higher speeds than usual. Both steam and exhaust cam rods have efficient unhooking devices, so that the valve gear can be worked by hand to facilitate starting and warming up. The valves are double ported, with very short travel, and, hence, have very little wear. The dash-pot levers are placed on the valve stems within the opening of the bonnet, and, therefore, are well supported on both sides to reduce wear. The releasing gear hooks and latch block trip plates have eight reversible wearing edges. All valve-gear connections are made to run as nearly noiseless as possible. The links have bronze connections with key adjustments. The governor is of the high-speed, center-weighted, fly-ball type, with motor and micrometer attachment for changing speed from switchboard to regulate for throwing in parallel. It is placed on the first gallery platform, and is easily accessible. Both cylinders are under control of the governor. The intermediate rocker arm supports for the eccentric rods are of box section, strongly bolted to the guide barrel, and are reinforced by braces from the "A" frame.

The fly-wheel is made in eight segments, a section of the rim and one arm to each segment. These segments are carefully planed and fitted at the joints, and are bolted to the hub with turned steel bolts, holes being reamed for a driving fit. The rim is clamped together with steel arrow-headed links, which are shrunk in place. The hub is in two separate discs forced upon the shaft. These discs are drilled and reamed and are bolted to the arms with turned steel bolts.

The main bearings are lubricated by a continuous stream of oil, furnished by an oil pump driven from the eccentric. The oil is pumped from a tank, located beneath the floor, to two receivers, which are located over each main bearing cap. From there it flows by gravity to all parts of the journal. The bottom box of these journals is cored out and arranged for water circulation. The eccentrics, cross-head slippers, cross-head and crank pins are oiled from a gravity feed system by multiple sight-feed tanks located on the upper part of the engine. The cross-head slippers have wipers on the bottom end, which dip into reservoirs at the bottom end of stroke, insuring perfect lubrication of the guides. All the valve gears, rocker arms, etc., are lubricated from grease cups. The engine is thoroughly furnished with oil guards and shields to prevent oil from being thrown on the floor. The eccentrics are entirely enclosed, to prevent oil from creeping along the shaft and reaching the generator.

These engines will be built in sizes ranging from 16 ins. and 32 ins. by 36 ins. stroke to 48 ins. and 96 ins. by 60 ins. stroke.

◆

THE MAGNETITE ARC LAMP.

During the past few years various means have been devised for improving the efficiency of the arc lamp, the improvements consisting for the most part in the addition of metallic salt to the carbon, which evaporating in the arc makes this luminous and hence increases the amount of light delivered by the lamp. The addition of such substances, however, entails many difficulties and also precludes the use of an air-tight globe owing to the dust which is produced when the lamp is burned. The General Electric Company has brought out an arc lamp in which magnetite, or the black oxide of iron, plays an important part. In this lamp the negative electrode consists of magnetite and is consumed. The positive terminal is not replaced, but is a copper segment and constitutes a permanent part of the lamp. The production of a non-consuming, positive electrode is made possible if this be given a sufficient heat conductivity which will not permit it to become too hot, but sufficiently so to avoid the deposition of material on it. With the magnetite are incorporated other substances, as arc-steadying compounds, titanium compounds for increasing the efficiency, etc. With the use of such an electrode rates of consumption of twenty to thirty hours per inch are produced, which gives a life of 150 to 200 hours for an 8-in. electrode. With very little sacrifice of efficiency, a life of 500 to 600 hours is produced, which, while obviously valuable in cases where trimming is difficult, is hardly needed for general illumination, since a street lamp should be looked after oftener than this. In the magnetite arc all the light comes from the arc flame and an arc length from ¾ to 1⅛ ins. is therefore most efficient. In order that a constant volume of light may be produced, the arc length should be constant, which calls for a feeding mechanism different from the floating system of the carbon arc lamp and which is obviously much simpler. The operation of the magnetite arc lamp is as follows: When the current is turned on the arc is struck by separating the electrodes to a definite distance, say ⅞ in. The electrodes are then locked in this position and remain fixed for some hours, when by the consumption of the negative electrode the arc length, and thereby the arc voltage, has increased sufficiently to operate the feeding mechanism which resets the arc to its original length.

A HIGH-SPEED MOTOR-DRIVEN PUMP.

The operation of pumping machinery by electric motors offers, especially in mines, many obvious advantages. The electric-driven pumps, however, have had one drawback which, while not serious, had nevertheless to be taken into account. This was the necessity of toothed gearing, belts or other devices to transfer the power from the rapidly revolving motor shaft to the slow-moving crank-shaft of the pump. In the pump which we illustrate herewith these objectionable features have been eliminated by the simple expedient of connecting the pump plungers to cranks mounted directly upon the shaft of the motor. This pump has a capacity of about 250 gallons per minute against 1000 ft. head when running at a speed of about 300 revolutions. Its mechanical efficiency is claimed to be over 93 per cent, approximating closely that of the highest types of large steam pumping engines. The pump is of the duplex type, the cranks at the opposite ends of the motor shaft being set at right angles to each other. The plungers are of the outside-packed pattern and the two plungers of each pump are connected by side rods. The plungers are 3½ ins. in diameter and have a stroke of 5½ ins. The pump and motor are mounted upon a rigid box-girder frame and the unit is self-contained and occupies a relatively small space. It contains many novel features of construction, and careful attention has been given to the design of the internal parts, as well as to the running parts and oiling devices. This type of pump, which has only lately been introduced, has many advantages, including simplicity of construction, small space requirements, cheapness of installation and attendance. The pumps are built by the Blake & Knowles Steam Pump Works, New York, in capacities of from 200 to 4000 gallons per minute and for heads varying from 100 to 2000 feet.

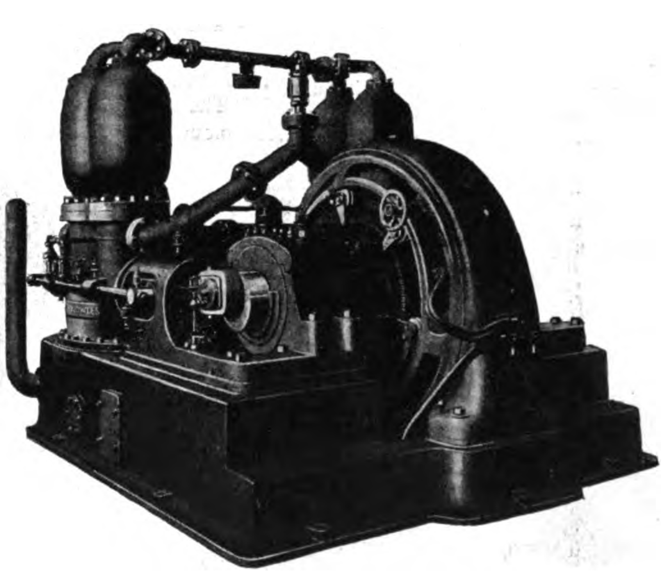

FIG. 1.—HIGH-SPEED MOTOR-DRIVEN PUMP.

New Apparatus and Appliances

ELECTRICIANS' TOOL CHESTS.

In an article under the above title which appeared in this colume last month, it was erroneously stated that the chests were manufactured by William Vanderman. While Mr. Vanderman is the inventor of these chests, the manufacturer is the Vanderman Plumbing and Heating Company, of Willimantic, Conn.

FIBERLITE SHADE AND HOLDER.

The Applied Device Company, of Springfield, Mass., has brought out the shade and holder shown by Fig. 1 herewith. The holder is made of heavy wire, all in one piece, and clamps the lamp socket with a catch similar to a guard. It fastens to the inside of the shade, and any tendency to pull it off only makes it hold more securely. The shade is made from a fibre similar to that used for the lining of sockets, and is colored mottled green on the outside and pearl gray inside. The fibre is finished under pressure, which gives it a glossy finish. It is tough and springy and is not easily crushed out of shape.

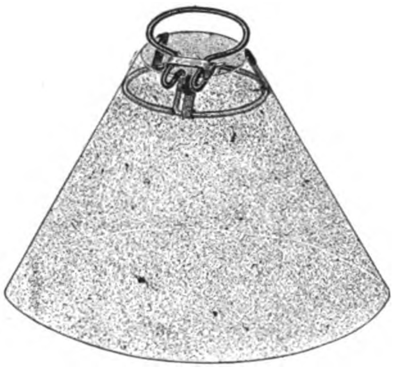

FIG. 1.—FIBERLITE SHADE AND HOLDER.

IMPROVED POP SAFETY VALVES.

The Crane Company of Chicago, Ill., has brought out a number of improved forms of pop valves for stationary, marine, locomotive and portable boilers, whose construction embodies a self-adjusting feature which automatically regulates the pop of the valve. The self-adjusting auxiliary valve and spring are entirely independent of the main valve and spring. The steam in the pop chamber finds a passage through holes or ports into an annular space provided in the auxiliary valve or disc, and by reason of the light auxiliary spring this pressure lifts the auxiliary valve and allows the steam in the pop chamber to gradually escape, thus permitting a greater range in setting pressures with the least waste of steam, and at the same time supplying a cushion or balancing medium which prevents any chattering or hammering and affording easy action in closing. The encased spring valves are constructed with a casing or chamber enclosing both springs and protecting them against the action of the steam. This form of valve is also useful where a number of valves may be connected to one main exhaust or discharge pipe. The encasing spring chamber extending over a greater portion of the top surface of the main valve, prevents any retarding action from the steam due to back pressure, which might be caused by one or more valves opening slightly in advance of another, in having any material effect on the free opening of the main valve.

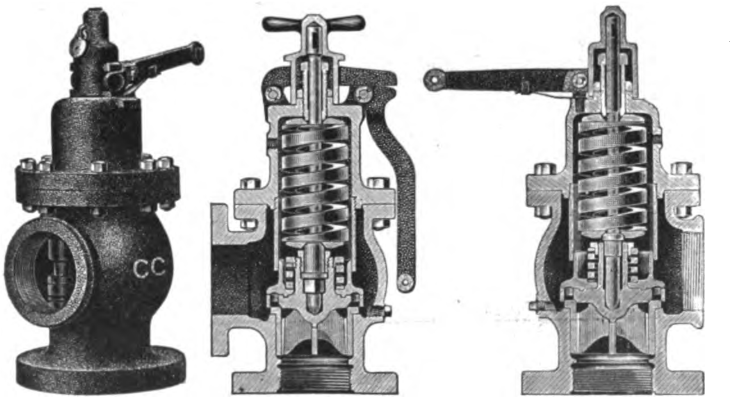

FIG. 2.—POP SAFETY VALVES.

THREE-BEARING GENERATORS FOR GAS-ENGINE PLANTS.

The numerous calls for a line of small generators for operation in connection with gas engines, has prompted the Commercial Electric Company, of Indianapolis, Ind., to prepare for the market a line of machines having three bearings and a heavy balance wheel mounted upon the shaft for the purpose of overcoming the fluctuations in speed occasioned by the irregular impulses of the gas engine. This construction makes it possible to secure good lights with almost any practical gas engine; makes unnecessary the awkward counter shaft previously used in belt dynamo installations, and subjects the dynamo shaft to no damaging strain as is the case where the heavy balance wheels is used on any two-bearing dynamo. The generator construction throughout is that of their standard yoke type with the exception of the bearings. The armature is carried by three pedestals mounted upon a cast iron base each of which contains a bronze-lined self-oiling bearing. The paper pulley is mounted direct upon the hub of the balance wheel and the combined "paper pulley" is supported closely, on both sides, between two of these pedestals. This arrangement, together with an extra heavy shaft, makes impossible any strain from the weight of the balance wheel or the pull of the belt, upon the portion of the shaft on which the armature is mounted. The entire machine is carried upon sliding rails with hand wheels and screws by which it can be shifted for tightening the belt. These dynamos are made in sizes ranging from ½ kilowatts to 30 kilowatts.

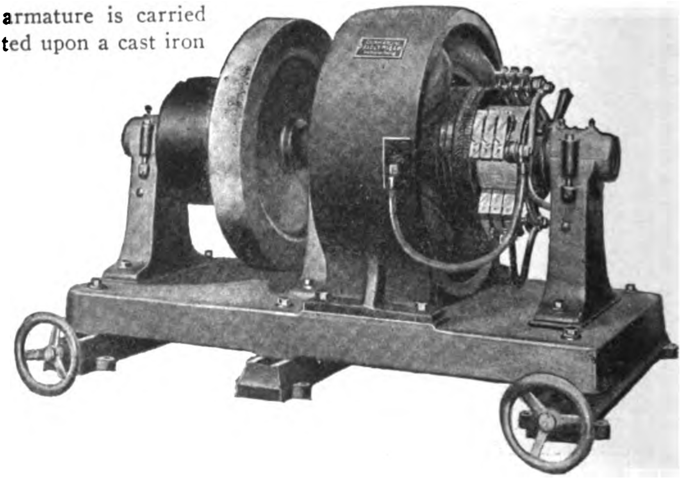

FIG. 3.—THREE-BEARING GENERATOR.

500-VOLT CIRCUIT SWITCH.

The Hart & Hegeman Manufacturing Company, of Hartford, Conn., has brought out the switch shown in Fig. 4 herewith, which has been designed to operate safely and successfully on a 500-volt circuit with 20 amperes, and which, it is claimed, will break a current of 75 amperes at 500 volts. This is accomplished by passing the switchplate through a narrow slot between two porcelain barriers. The air space is so small that the manufacturer claims it is impossible for the spark to follow.

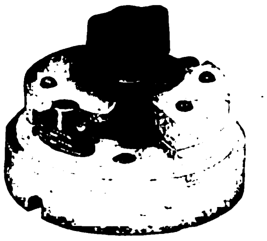

FIG. 4.

AUTOMATIC OIL FILTER.

The Burt Manufacturing Company, Akron, Ohio, is the manufacturer of the oil filter shown in the accompanying sectional view, designed to receive the condensation from oil separators and exhaust heads and to automatically separate the oil from the water, while at the same time purifying it. The water is drained to the sewer and the oil, rising into a separate chamber, overflows into the oil reservoir. The filter is made in twelve different sizes, with filtering capacities of from 300 to 500 gallons per 24 hours. The mixed oil and water is received through the inlet at the top of the filter and then passes through a layer of waste, which collects all the heavier impurities of the oil. Then it passes through the perforations in the bottom of chamber *B*, following the course indicated by the arrows, into tube *C*, and from here on to the filter plate *D*. The increased weight of the water has a tendency to keep the oil back in tube *C*, but when the pressure of the oil in chamber *B* becomes sufficient the oil is forced down and spreads over the plate *D* in a very thin film. This, it is claimed, constantly changes surface and grows thinner as it travels from the center to the circumference of plate *D*, thus exposing every particle of oil to the action of the water. It then flows on to plate *1D* and *2D*, going through the same process in each case. When the oil leaves the plate at *2D* it is said to be in a finely divided state and thoroughly washed by the water. It is separated from the water by gravity, and all the remaining impurities settle in chamber *E*, from which they can be drained to the sewer by opening the gate valve at the bottom of the filter. From the plate *2D* the oil rises and again filters through *F*, another layer of waste, into the pure oil chamber, where it accumulates until it overflows into the oil reservoir. The water is automatically separated after it passes down the tube *C* and reaches the bottom plate, on account of its being heavier than the oil, and the surplus water passes into the pipe leading to the automatic water-separating device.

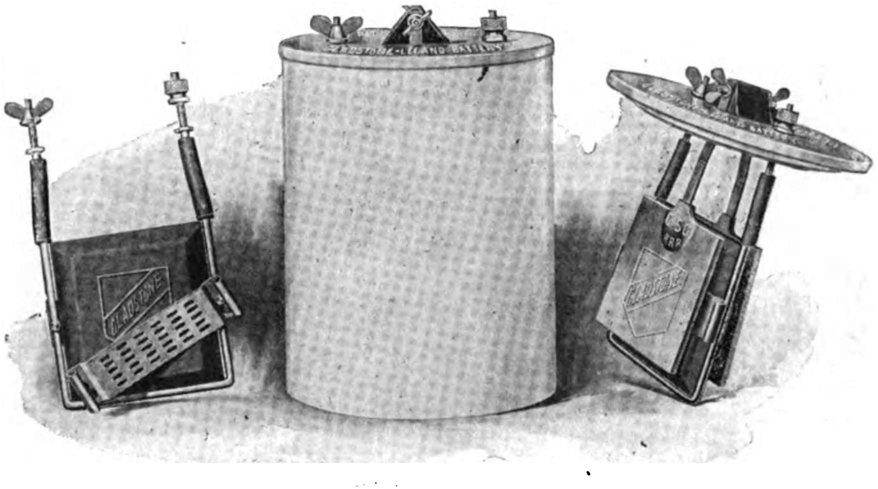

FIG. 6.—GLADSTONE-LALANDE PRIMARY BATTERY.

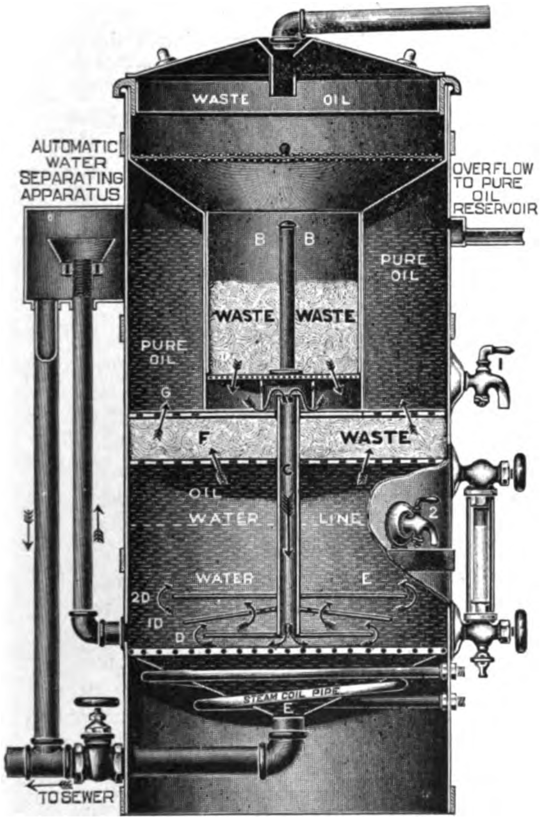

FIG. 5.—AUTOMATIC OIL FILTER.

THE GLADSTONE-LALANDE PRIMARY BATTERY.

The battery shown in the accompanying illustration is an improvement on the type of battery invented by De Lalande & Chaperon, of which there are several modifications on the market at the present time. In the Gladstone-Lalande battery the negative electrode is composed of a plate of agglomerated oxide of copper, having its surfaces reduced to the metallic state. This copper oxide plate is carried in a supporting hanger, made of copper rod formed into a U-shaped frame, the two free ends of which are threaded to receive clamping nuts, by which it is fastened to the porcelain cover of the battery. This supporting hanger is provided with two perforated, flat spring, copper clamps, attached to the opposite sides of the hanger. One of these spring clamps is riveted at each end to the hanger, and the other is detachable, having slotted eyelet holes at each end which fit over the two rivet heads on the sides of the hanger; the clamp is locked in position by being pulled slightly in a downward direction. The copper oxide plate is so placed in the hanger that one of its flat surfaces bears against the fixed spring clamp. The detachable spring clamp is then locked to the hanger, so that it bears against the other flat surface of the oxide plate, which is held firmly between the two spring clamps. The advantages possessed by this form of construction are that when the battery needs to be recharged the exhausted oxide of copper plate can be removed from the hanger and a new one substituted with the least possible loss of time, and without soiling the fingers. The wide surfaces of contact presented by the perforated spring clamps render it unnecessary for any cleaning or sandpapering of these parts when recharging the battery. The positive electrode consists in all cases of two flat plates, composed of an alloy of zinc and mercury, which are suspended from the cover. In some models these flat zinc plates are cast on an inverted U-shaped hanger, having a threaded extension which passes through a hole in the cover, to which it is clamped by a suitable nut. In other models (as shown in the illustration) the two zinc plates are cast on separate stems, having a hole at the upper extremity which allows them to be bolted to the projecting knob on the top of the cover, which is provided with a horizontal hole to receive a threaded bolt for this purpose. The electrolyte in all cases is a 20 per cent solution of pure caustic soda, and a layer of pure mineral oil is poured on top of the solution to prevent evaporation and creeping. These batteries are manufactured by the Battery Supplies Company, Newark, N. J.

AN AUTOMATIC LAMP SHADE.

The accompanying illustration shows an automatic lamp shade which the General Incandescent Arc Light Company, of New York, has placed on the market. The shade and holder can be instantly put on or removed from any size of electric light from four to twenty-four candle-power without removing the lamp from its socket, adjusting itself to the lamp automatically. In addition to the economy in time with the use of this shade, the manufacturer claims that it will double the amount of illumination thrown down by the lamp. The shade may be used on an upright portable lamp by bending the arms up to right angles and adjusting from inside the holder.

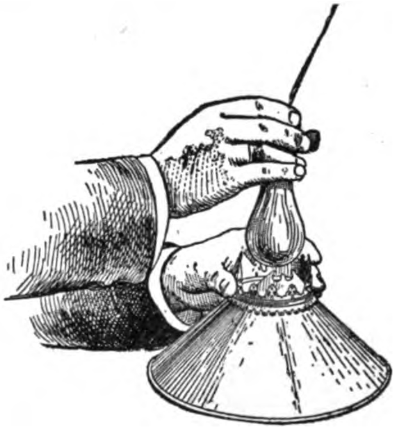

FIG. 7.—AUTOMATIC LAMP SHADE.

BOSS WEATHER-PROOF ENTRANCE BUSHING.

Fig. 8 herewith shows a weather-proof entrance bushing made by the Belcher & Loomis Hardware Company, of Providence, R. I., which has the approval of the underwriters. The cap is detached by simply

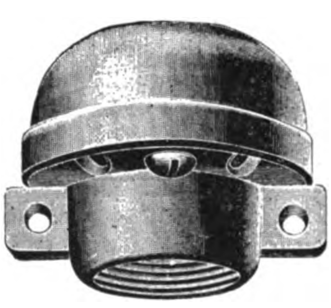

FIG. 8.—ENTRANCE BUSHING.

loosening the screw, and no fishing is required where the wires enter. The bushing prohibits any moisture getting in where wires enter the pipe, and one of the principal uses to which it may be put is in connection with a transformer where the house wires enter the conducting pipe. It makes a permanent and serviceable fitting and is easily installed.

CRESCENT RECEPTACLES FOR ELECTRIC LIGHT WORK.

The receptacle shown by Fig. 9 herewith is made by the Crescent Electrical Manufacturing Company, of Rochester, N. Y., from extra heavy porcelain, and has no exposed metal parts. Its use makes possible the easy reversal of wires from either back or front connections, and does away with the need of carrying a number of different styles in stock. The illustration is half the actual size of the complete receptacle.

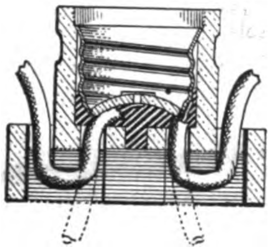

FIG. 9.—CRESCENT RECEPTACLE.

SOCKET PLUG FOR FLASHING LAMPS.

The Phelps Co., of Detroit, Mich., is introducing a socket plug for flashing incandescent electric lights on and off at the rate of about fifteen times a minute. This plug fits any Edison-type socket and holds any ordinary incandescent lamp. Each plug is complete in itself. Inside of an ordinary Edison base, there is a mechanism which makes and breaks contacts at intervals. This mechanism is operated solely by the lamp itself. As the lamp burns it generates a certain amount of heat in the socket, which causes a small thermostat to expand, thus breaking the contact, and when the lamp has cooled sufficiently the light is again automatically switched on. This is continued throughout the life of the plug, which is said to outlast several lamps. The contacts are of heavy platinum. The plug is known as the "Skedoodle" socket plug and can be used on either alternating or direct-current circuits.

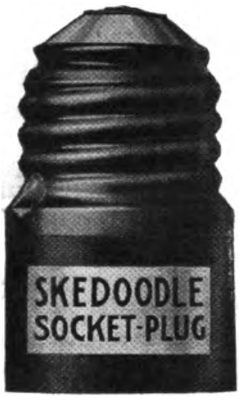

FIG. 10.

NEW SCREW-CUTTING BENCH LATHE.

The Seneca Falls Manufacturing Company of Seneca Falls, N. Y., has brought out the screw-cutting bench lathe shown by Fig. 11 herewith. The head stock has a large hollow spindle, made from a crucible steel forging, with draw-in chuck for split collets up to ½ in. capacity, and phosphor-bronze boxes with improved end-thrust ball bearings. The cone pulley has three steps for wide belt and with strong back gears gives six changes of speed. A push pin on the head gear allows the cone to be instantly locked or unlocked without using a wrench. The tail stock is of the curved or cut-under pattern, which allows the compound rest to swing around parallel with the ways and over the base of the tail stock, with room to operate the feed-screw handle. The spindle has an improved locking device, and the tail stock is provided with side adjusting screws for turning tapers. There is a long bearing on the bed and it is locked in such a manner as to render it firm and rigid. The carriage has a long bearing on the ways and is gibbed to the bed both front and rear. A cam-locking device locks the carriage to the bed when using the cross feed. The cross-feed screw has a graduated collar which reads in thousandths of an inch and can be set at zero in any position. Plain and compound rests are regularly furnished and easily interchanged. The base is graduated and renders the compound rest capable of fine adjustment. The automatic cross and longitudinal feeds are actuated by a phosphor-bronze worm on the lead screw, receiving its power from the head spindle through spur gears. The lead screw is splined and simply acts as a feed rod, hence the only wear on the threads is in screw-cutting. The automatic feeds are almost indispensable for a large variety of work, as they secure more accurate and smoother surfaces. The range of feeds is very large. The range for screw-cutting is extra large, cutting all standard threads, right or left (including 11½ in. and 27 in.), from 3 to 64 without compounding the gears and nearly all threads by compounding. Patented spring nuts are used in connection with split washers to hold the change gears in place. They are easy and convenient to operate and allow quick shifts of the change gears. The bed is 46 in. long, broad, deep, thoroughly well braced and accurately proportioned throughout. The rated swing is 9 ins, but it has an actual swing of 10 1-3 ins. over bed and 24 ins. between centers.

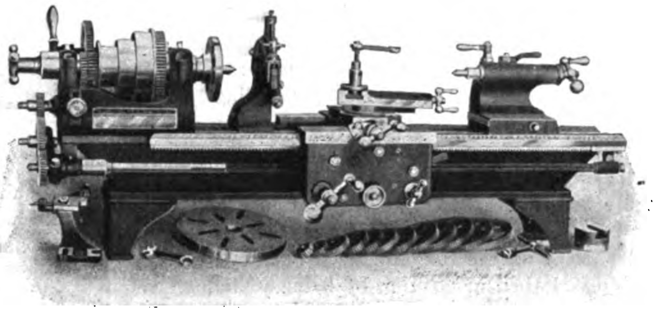

FIG. 11.—SCREW-CUTTING BENCH LATHE.

NEW BOOKS.

Wireless Telegraphy. By William Maver, Jr. New York: Maver Publishing Company. Cloth; 212 pages, 6 x 9 ins.; 121 illustrations. Price, $2.

Anyone who is familiar with Mr. Maver's "American Telegraphy" would naturally expect the present work to be of the highest merit; perusal of the book confirms the expectation. The author has dealt with the more complex subject of electrical wave telegraphy in the same simple, clean-cut style that characterizes his former work, and without any sacrifice whatever of either accuracy or clearness of exposition. There are a very few slips in diction and one or two bits of slightly careless technical description, such as "the lines of force of the primary wire" (of an induction coil), page 7, and "an oscillating current disrupts this bridge and thereby renders the electrolyte non-conducting," page 112. The lines of force are set up by the current in the primary wire, and it is the bridge, not the electrolyte, that was conductive before it was disrupted. These, however, are of infinitesimal importance compared with the general merit of the book.

The author gives an outline of the early work done by Preece, Phelps and others in other classes of space telegraphy, and explains fully, but not verbosely, the fundamental principles of Hertzian wave telegraphy, the variations due to the several workers in the field, and the practical operation of the several systems. He also describes very thoroughly the detail devices used or experimented with by Marconi, De Forest, Fessenden and others. The use of mathematics is limited to a few very simple algebraic formulas, almost all of the exposition being made in plain English. The book is cordially commended to all who are interested in its subject.

Ready Reference Tables. By Carl Hering. New York: John Wiley & Sons. Soft leather; 212 pages, 4 x 7 ins. Price, $2.50.

This is a book of conversion tables, or lists, rather, which include every unit of weight, length, surface, volume, pressure, work, energy, power, heat, temperature and money that has ever been put on record in any civilized country, together with all of the electromagnetic, electrostatic, photometric and physical units. Its scope, therefore, is enormous, and if the material were arranged appropriately the book would be correspondingly valuable. Unfortunately, the author considers, according to the preface, that the usual class of "tables of weights and measures . . . is quite unsuited for ready reference," and prefers to limit himself to lists giving merely the equivalents of each unit. These, of course, are extremely useful, but there is no comparison between them and the more familiar tables which save most of the labor of multiplication in reducing a given value in one system of units to the equivalent value in another system. The short expository text preceding each section of the work is highly useful and well written. Another commendable feature is the provision of a list of symbols and abbreviations at the front of the book with numbers showing on what page or pages each symbol or abbreviation is used; this is particularly advantageous where one symbol is used in two or more senses, which is, of course, unavoidable in a book of this scope. The choice of symbols is not always consistent, however; on pages 22 and 115, for example, *Q q* represent coulombs, while on page 116 *C c* are used; again, *B. T. U.* represents both Board of Trade unit and British Thermal unit unnecessarily, since it is a simple matter to distinguish by using *B. Th. U.* or *B. t. u.* to represent the heat unit. The material in the book is jammed together in the most reckless disregard for the eyes or convenience of the reader, in many cases making the aid of a ruler necessary in order to trace along a line without losing the line. The price asked for the book removes the only possible excuse that might have been offered for this unseeming crowding, as well as for the extremely economical use of conversion tables proper.

SOME EXHIBITS AT THE ST. LOUIS EXPOSITION.

Although the exhibits of the electrical and allied industries at the Louisiana Purchase Exposition are not fully completed at this writing, enough are installed to impress one with the vast and diversified character of the exhibits generally, not to speak of the stupendous amount of labor involved in their selection and arrangement. So numerous are the points of interest, and so prominently are they brought out, that we regret space limitations permit only a passing mention of some of the most important of those which naturally fall within the scope of this journal.

The booth of THE AMERICAN ELECTRICIAN is arranged for the comfortable reception of visitors. Complete files of the various technical journals and a library of electrical books published by the McGraw Publishing Company are placed at the disposal of visiting engineers. A complete record of all those interested in electrical industries who go to the Exposition is kept in a register provided for that purpose. Those who desire to write and those who desire to correspond will find ample facilities for so doing. The booth is below the office gallery of the Electrical Department, and a view is given in the accompanying illustration.

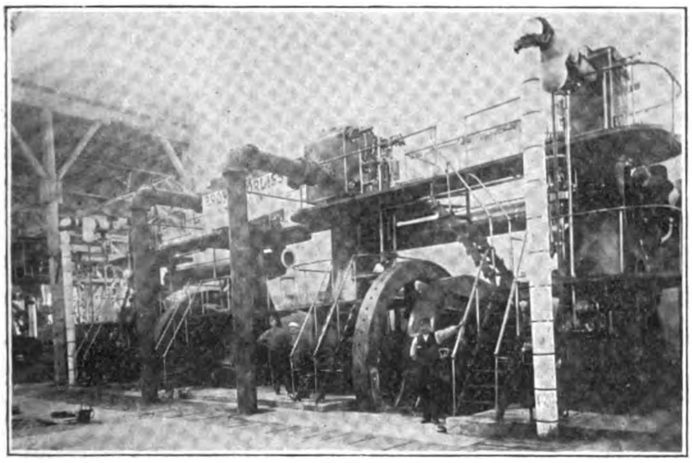
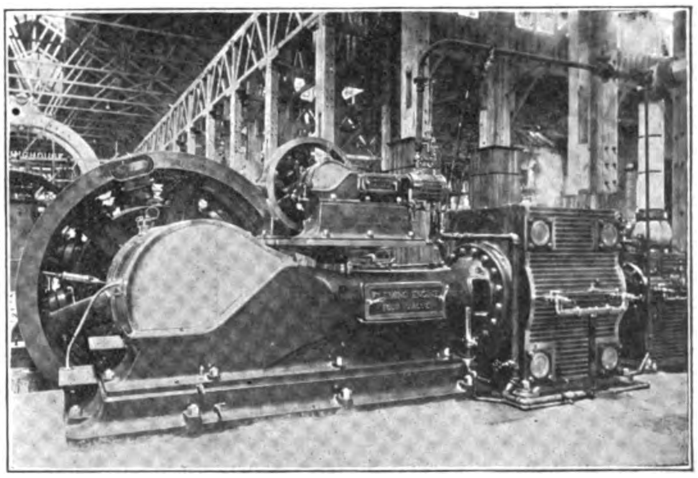
AMERICAN ELECTRICIAN
The ENGINEERING RECORD
ELECTRICAL WORLD AND ENGINEER
STREET RAILWAY JOURNAL

M'GRAW PUBLISHING COMPANY'S BOOTH.



BROWN-CORLISS ENGINE COMPANY'S EXHIBIT.



HARRISBURG FOUNDRY AND MACHINE WORKS' EXHIBIT.

BROWN-CORLISS ENGINE COMPANY, Corliss, Wis., has two engines in the exhibitors' power plant, which drive 500-kw. railway generators for the Intramural railway. These are vertical cross-compound condensing engines having a rated horse-power capacity of 750 with 150 pounds steam pressure. The cylinders are made double ported and the ports are made large enough so that the piston heads partially cover the pockets at the end of the stroke. The movement of the valve-gear and dash-pot is very small. All these things tend to make possible quick action of valve-gears and quick opening of steam ports.

HARRISBURG FOUNDRY AND MACHINE WORKS, Harrisburg, Pa., have a 600-h.p., four-valve, Fleming engine on exhibition in Machinery Building. This engines operates at a speed of 150 r.p.m., and is remarkable for the smoothness of its operation. It is direct connected to one of the Crocker-Wheeler generators which furnishes current for the Intramural railway. The engine has cylinders 15 ins. and 40½ ins., with a 26-in. stroke. The governor is located on the shaft and acts on one of the eccentrics. There are three eccentrics on the engine, one of which is controlled by the governor and therefore controls the point of cut-off of the high-pressure cylinder. The second eccentric is fixed on the shaft and controls the inlet valves of the low-pressure cylinder, each having its point of cut-off fixed. The third eccentric opens and closes the exhaust ports, four of which are provided in each cylinder. Automatic lubrication is employed. The crank chamber is closed and partly filled with oil and the crank-pin and guide rods are lubricated by the splash of oil in the crank chamber. Near the top of the crank chamber, above the lever and the main bearing, is a trough which receives some of the oil splash and delivers it by gravity to the main bearing.

THE AUTOMATIC ELECTRIC COMPANY, Chicago, attractively displays its telephone apparatus. This includes two complete working automatic exchanges of the 10,000 type, each with 100 stations installed. These exchanges, which are now giving service throughout Electricity Palace, are connected together by a system of trunks similar to those used in connecting branch exchanges. The selection of trunks is, however, performed automatically. The telephones exhibited are of three types—wall, desk and pedestal. All are fitted with the regulation calling dial for conveying electrical impulses to the switches at the central office. A toll board of ten stations is also in service, demonstrating the manner in which toll connections are given to users of automatic telephones. The remainder of the apparatus is of the same general character as that used in any modern telephone exchange, save the "tell-tale" board. This is a device for the instantaneous location of trouble and consists of a number of lamps and a magneto bell. In case of trouble, this magneto bell by its ringing arrests the attention of the attendant and a lamp glows, by the position of which on the board the location of the trouble can be instantaneously ascertained.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., has an interesting exhibit characterized by light and motion. There are sixty arc lamps in and around the space, giving a most brilliant illumination. A ten-panel switchboard is provided for distribution and regulation. Two supplies of current are received from the building sub-station, one a three-wire, 220-volt, direct-current, and the other a 500-volt, direct-current. A series of motor-generators convert this current for the different applications. Transformers ranging in capacity from 1 to 500 kilowatts are displayed, as well as windings and sections which illustrate the methods of insulation. The different types of wattmeters made by the company are shown under operating conditions on the switchboard panels, and all the principal parts used in the construction of these instruments are mounted in cases. At the corner of the two aisles a standard carries a number of Fort Wayne oscillating fan motors. Not the least interesting item in the space is an arc light machine constructed by Mr. J. J. Wood in May, 1879.

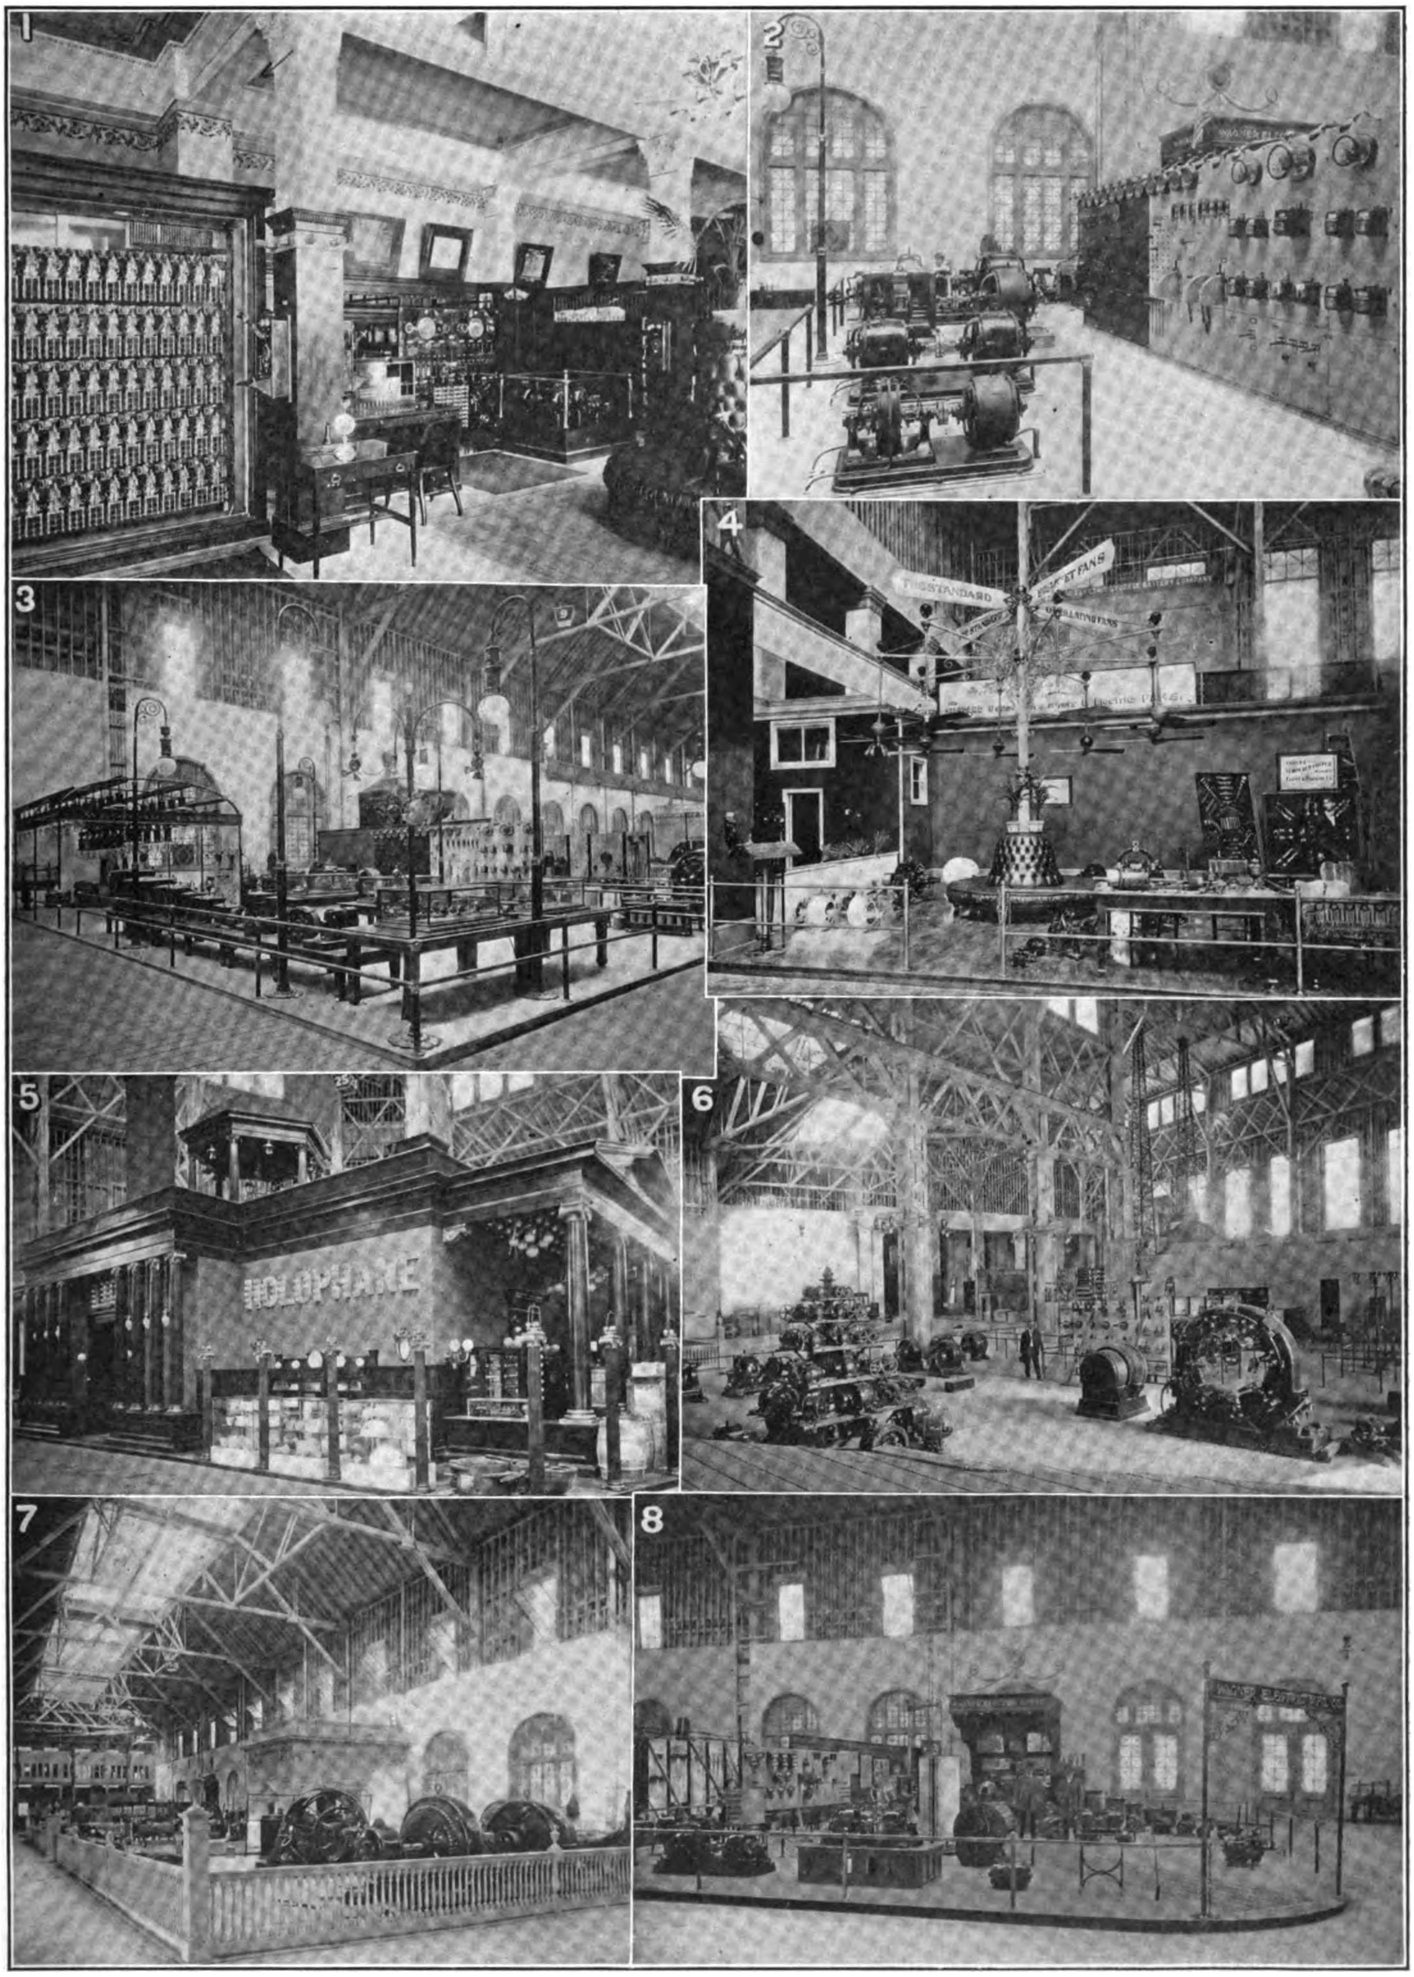
THE ROBBINS & MYERS CO., Springfield, Ohio, displays its "Standard" motors and dynamos. These machines are shown in sizes ranging from 1-30 horse-power to 15 horse-power; these sizes include all the machines built by the company. One of the machines is dismantled in order to show its construction, insulation and interchangeable parts. An immense revolving fan motor rack forms a unique feature of the exhibit. From the extremities of each of the six arms of the rack is suspended a ceiling fan motor and above each arm is a desk fan motor with the plane of the fan nearly parallel with the arm. The twelve fans are all revolving, the desk fans causing the entire rack to rotate, thus keeping the air in that section in circulation. Another interesting exhibit item is a magnetic separator, used for extracting particles of metal from the cotton before it reaches the gin.

HOLOPHANE GLASS COMPANY, New York, has a most striking exhibit; 1000 electric incandescent lamps being used for illumination. The booth is in the form of a Grecian temple, fronting on three aisles in Section 25. Over the central doorway electric lights covered with Holophane globes form the word "Lux" in white letters, and on each side is suspended a large Holophane 16-in. ball hanging by three chains. On the door casing are torch brackets surmounted by pillars topped with Holophane globes containing three colored lamps. These are suitably connected to a Reynolds flasher, so that a change of color occurs at different intervals. Between these pillars are plate-glass cases containing samples of the different kinds of prismatic globes and reflectors manufactured by the company. The entrances over the side aisles are Grecian porches, the ceilings of which are studded with electric lights of different colors. The center room of the interior is divided into two portions, showing two dining-rooms identically fitted so far as fixtures and furnishings are concerned, but in one Holophane globes are used and in the other the ordinary globes, effectively illustrating the difference in the distribution of light occasioned by the use of the prismatic globes. On each side of this room there is another apartment suitably divided to show twelve dark rooms for comparing the different forms of Holophane globes and Pagoda reflectors with other kinds of globes and reflectors. The ceilings and walls are all of paneled oak, and in the center of the main room is an expensive fireplace.

WESTERN ELECTRIC COMPANY, Chicago, occupies a space fronting on two main aisles. In the center is a motor-generator equipment, consisting of two 100-kw. frames, the motor side taking current at 500 volts and the generator side delivering current at 220 volts. This unit operates in conjunction with a 15-kw. compensator, permitting the use of 110-volt current. The center space also contains two switchboards, one for controlling the operation of the apparatus receiving current from the motor-generator, and having all the necessary switches, circuit-breakers, ammeters, etc. The other board is for display purposes only, and on it are circuit-breakers, knife switches, voltmeter switches and kindred apparatus. In the extreme northeast corner of the space a small machine shop is installed, showing the actual operation of modern machine tools driven by Western Electric motors on the three-wire, multi-voltage system. In the northwest corner is a line of power motors arranged in the form of a pyramid, the smallest ones at the top. In the southwest corner is a series alternating arc light equipment, consisting of a full line of transformers, regulators and switchboards. Opposite this are ornamental arc lamp stands from which are suspended various types of arc lamps. There are also a number of sewing machine motors in operation. Fan motors and ceiling fans are distributed throughout the space, suspended from overhead, and a number of boards containing supplies manufactured by the leading companies throughout the country.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, exhibits its new street railway motors. Railway motors of 550 horse-power are shown in its space in Electricity Palace, one of which is open. Others are to be mounted on trucks and shown in operation in connection with a railway controller. The motors are arranged for lubrication by means of pads mounted on springs and bearing against the journals and are built to open from below. Ventilation is provided through the field cores, which are of laminated iron. In the pole tips, every other sheet of steel has been omitted, thus reducing by one-half the amount of iron in the tip. A prominent feature of the company's exhibit is a 500-kw., 25-cycle, rotary converter intended for railway use. This supplies current for the operation of the street railway motors in the exhibit. In connection with this converter are three 150-kw. transformers which step down the supply from 6600 volts to that required by the rotary. A motor-generator set with a synchronous, 60-cycle, three-phase motor and a direct-current generator with a capacity of 40 amperes at 550 volts is also included in the railway portion of the company's large exhibit. A large three-phase alternator partly assembled is exhibited for the purpose of illustrating the method of coil construction and insulation as well as the arrangement of the coils. A 250-kw. transformer water and oil cooler for high-tension voltage of 20,000 and a low-tension voltage of 2300 is shown. The company has equipped its space with a testing table and instruments to show to interested visitors the performance of the working apparatus in its exhibit. A large amount of space is given to the display of Bullock motors driving machine tools. The company occupies a space of 104 ft. x 54 ft. in Electricity Palace and has provision for the entertainment of visitors. One of the most prominent features in the Palace of Machinery is the 3500-kw., three-phase, 25-cycle, 6600-volt Bullock generator driven by an Allis-Chalmers combined vertical and horizontal compound engine. While available for any kind of service, this unit has frequently been used to carry the decorative lighting load, the gradual evolution from darkness to full brilliancy being accomplished by manipulating the field excitation.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has an exhibit whose purpose is to demonstrate the applicability of the single-phase motor for general power uses. The single-phase motor is shown driving machine tools, organ blowers, dough machines and ventilating fans. The speed of the machines is varied, giving changes from 8 to 1 by means of the controller. There are also on exhibition motor-generator sets, a direct-current generator being driven by a single-phase motor. The application of this motor to house pumps is demonstrated by its different equipments. The action of the motor is controlled automatically by the height of the water in the tank. This opens



A GROUP OF INTERESTING EXHIBITS.

(1) Automatic Electric Company. (2) and (3) Ft. Wayne Electric Works. (4) The Robbins & Myers Company. (5) Holophane Glass Company. (6) Western Electric Company. (7) Bullock Electric Manufacturing Company. (8) Wagner Electric Manufacturing Company.

or closes the switch, the cutting out of the starting device being controlled by the motor itself. The company also displays a full line of its well-known transformers of the air-cooled, self-cooled and water-cooled types. A five-panel switchboard is equipped with its high-tension switches and instruments.

National Electric Light Association Convention Notes

LORD ELECTRIC COMPANY, Boston, sent F. W. Lord to the Convention.

SIMPLEX ELECTRICAL COMPANY, Boston, sent Miss J. H. Mason to the Convention.

BAKER & CO., INC., Newark, N. J., had its interests well cared for by Mr. J. J. Lowthian.

WESTERN ELECTRIC COMPANY, Chicago, Ill., sent Messrs. E. W. Rockafellow and A. C. Morse.

DOSSERT & COMPANY, New York, was represented by Messrs. J. J. Dossert and A. H. Willmont.

THE LUNDIN ELECTRIC & MACHINE COMPANY, Boston, was represented by Mr. E. C. Lundin.

AMERICAN ELECTRICAL WORKS, Providence, R. I., sent Messrs. T. B. Baker and W. J. Watson.

RICHMOND ELECTRIC COMPANY, Richmond, Va., sent Mr. W. H. A. Davidson as its representative.

DOUBLEDAY-HILL ELECTRIC COMPANY, Pittsburg, was ably represented in the person of Mr. C. P. Hill.

COOPER HEWITT ELECTRIC COMPANY, New York, had its interests looked after by Mr. G. C. Ewing.

MARSHALL-SANDERS COMPANY, Boston, had for its sponsors Messrs. Norman Marshall and S. A. Sanders.

HARVEY HUBBELL, Bridgeport, Conn., had an exhibit of his specialties which was in charge of Mr. T. S. McLean.

ALBERGER CONDENSER COMPANY, New York, was represented by Messrs L. R. Alberger and H. M. Montgomery.

J. G. WHITE & COMPANY, New York, was ably represented in the persons of Messrs. P. G. Gossler and H. J. Dowds.

HOLOPHANE GLASS COMPANY, New York, made its usual excellent showing. Mr. J. S. Codman was in attendance.

DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., had its interests ably cared for by President B. C. Kenyon.

HOLTZER-CABOT COMPANY, Brookline, Mass., was represented by Mr. C. W. Holtzer, who took an active part in the proceedings.

THE STANDARD VITRIFIED CONDUIT COMPANY, New York, had an attractive exhibit presided over by B. S. Barnard.

NEW YORK & OHIO COMPANY, Warren, Ohio, sent Secretary W. D. Packard to look after the interests of the Packard lamps.

AMERICAN DIESEL ENGINE COMPANY, New York, was represented by Messrs. N. McCarty and J. D. McPherson.

SPEER CARBON COMPANY, St. Marys, Pa., had its general manager, J. S. Speer, stop at the Convention on his way to Maine.

WESTON ELECTRICAL INSTRUMENT COMPANY, Newark, N. J., sent Mr. G. H. Moseman to look after its interests.

C. S. KNOWLES, Boston, was represented by Messrs. C. H. Clark, D. Kennedy, G. Ober, G. S. Hutchins, J. Keefe and H. M. Saben.

AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., was represented by Messrs. C. R. Bishop and H. C. Eddy.

BUCKEYE ELECTRIC COMPANY, Cleveland, Ohio, was represented by Mr. Le Roy P. Sawyer, manager of the Cleveland office.

McINTOSH, SEYMOUR & COMPANY, Auburn, N. Y., had an efficient representation in Messrs. J. A. Seymour and E. A. Merrill.

CHASE-SHAWMUT COMPANY, Newburyport, Mass., had its interests taken care of by Messrs. H. P. Moore and F. D. Masterson.

DE LA VERGNE MACHINE COMPANY, New York, was represented by Messrs. George Richmond, Seward Babbitt and H. Borgstedt.

MANHATTAN ELECTRICAL SUPPLY COMPANY, New York, sent Mr. J. W. McDonald to look after its interests at the Convention.

LOMBARD GOVERNOR COMPANY, Boston, sent its engineers, Dr. A. V. Garratt and Mr. R. B. Smith, together with Mr. R. N. Stafford.

JAMES G. BIDDLE, Philadelphia, the well-known dealer in electrical and scientific instruments, was a prominent figure at the Convention.

ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, had its interests well taken care of by Messrs. Charles Blizard and J. W. Cook.

ALBERT & J. M. ANDERSON COMPANY, Boston, was represented by Mr. A. Anderson. Mr. J. M. Anderson was also an occasional visitor.

THE OKONITE COMPANY, LTD., New York, had ample representation at the Convention in the persons of Messrs. W. L. Candee and G. T. Manson.

H. W. JOHNS-MANVILLE COMPANY, New York, made a large exhibit of its specialties, which was in charge of Messrs. J. Sachs and J. Humphreys.

NERNST LAMP COMPANY, Pittsburg, Pa., had among its delegates Messrs. G. C. Ewing, R. T. Vredenburgh, M. W. Hanks, E. R. Roberts and F. Gibbs.

SHELBY ELECTRIC COMPANY, Shelby, Ohio, sent Mr. C. W. Cartwright to represent it. One candle-power useful lights were distributed as souvenirs.

OSBURN FLEXIBLE CONDUIT COMPANY, New York, sent Messrs. C. E. Corrigan and S. B. Roulet to the Convention so that "Flexduct" would not be lost sight of.

THE BOSSERT ELECTRIC CONSTRUCTION COMPANY, Utica, N. Y., manufacturer of switches, switchboards, junction and outlet boxes, was represented by Mr. F. G. Scofield.

PHOENIX GLASS COMPANY, Pittsburg, had present in its interests Messrs. A. H. Patterson, and E. H. Peck, from the New York office, and E. P. Ebberts, from Pittsburg.

DEARBORN DRUG & CHEMICAL COMPANY, Chicago, Ill., was represented by President W. H. Edgar and Mr. W. B. McVicker, manager of the New York office.

GENERAL INCANDESCENT ARC LIGHT COMPANY, New York, had present in its behalf Messrs. P. H. Klein, A. Foster, F. Raymond, R. S. Hale and S. H. Blake.

WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, occupied a parlor on the first floor. Messrs. Layman, Godfrey, Faxton and Mustard were in charge.

NATIONAL ELECTRIC COMPANY, Milwaukee, Wis., had Mr. M. E. Baird to represent it at the Convention and to explain all the good points of the National alternators.

LOCKE INSULATOR MANUFACTURING COMPANY, Victor, N. Y., displayed a number of types of its insulators, which formed a prominent part of the Pettingill-Andrews exhibit.

PASS & SEYMOUR, Solvay, N. Y., the well-known manufacturers of porcelain specialties, were represented by Messrs. B. E. Salisbury, J. W. Brooks, A. M. Little and W. B. Hall.

THE STANDARD UNDERGROUND CABLE COMPANY, Pittsburg, Pa., sent Messrs. F. C. Crosby, T. E. Hughes, C. J. Marsh and W. C. Waldron to represent it at the Convention.

SUNBEAM INCANDESCENT LAMP COMPANY, New York, and the Fostoria Incandescent Lamp Company, Fostoria, Ohio, were represented by Messrs. F. S. Terry and B. G. Tremaine.

THE W. S. HILL ELECTRIC COMPANY, New Bedford, Mass., showed a complete line of its switchboards and panelboards. Messrs C. S. Mendell and T. N. White were in attendance.

MASSACHUSETTS ELECTRICAL CO. was ably represented by Messrs. C. E. Farrington, L. O. Dulcos and E. C. Green. An acceptable souvenir was distributed from the company's parlor.

SPRAGUE ELECTRIC COMPANY, New York, sent Messrs. H. G. Issertel, H. C. Farnsworth and A. Henderson, who looked after the company's interests in their usual efficient fashion.

NATIONAL CONDUIT & CABLE COMPANY, New York, had a delegation at the Convention including Messrs. G. J. Jackson, W. S. Eckert, F. S. V. Sias, J. B. Honan and J. A. McQuale, Jr.

THE HART MANUFACTURING COMPANY, Hartford, Conn.—President G. W. Hart was in attendance and made many new friends for the "Diamond H" switches manufactured by his company.

THE H. T. PAISTE COMPANY, Philadelphia. —Secretary E. A. Jenkins attended the Convention and interested many delegates in "P-K" rosettes and the other numerous specialties of his company.

JOHN A. ROEBLING'S SONS COMPANY was represented by Messrs. F. W. Harrington, G. W. Swan, M. R. Cockey, C. B. Cushing and A. Mann. They made no exhibit, but distributed souvenirs.

BRYAN-MARSH COMPANY, New York, was ably represented by Messrs. G. V. Williams, J. P. Williams, D. W. Eyman, E. H. Houghton, G. C. Keech, S. E. Doane, F. W. Godfrey and W. C. Ballda.

THE STANDARD ELECTRICAL MANUFACTURING COMPANY, Niles, Ohio, had the merits of its "Star" lamps most ably presented to many delegates by Secretary J. P. Gilbert, who attended the Convention.

HART & HEGEMAN MANUFACTURING COMPANY, Hartford, Conn., manufacturer of the well-known Hart switches, was represented by President Albert H. Pease.

GOULD STORAGE BATTERY COMPANY, New York, made no exhibit, but its representatives, Dr. W. E. Winship and Mr. E. L. Draffen, neglected no opportunity for sounding the merits of the Gould storage battery.

CROCKER-WHEELER ELECTRIC COMPANY, Ampere, N. J., had its interests well taken care of by Dr. S. S. Wheeler, President, A. L. Doremus, Secretary, and Messrs. R. L. C. Barnes, C. R. Metchcar and A. J. Newell.

THE STANLEY INSTRUMENT COMPANY, Great Barrington, Mass., exhibited a full line of its meters. The exhibition was in charge of Messrs. W. C. Andrews, S. O. Ochs, E. W. Gough, F. J. Alderson and F. W. Sanford.

SIMPLEX ELECTRIC HEATING COMPANY, Cambridgeport, Mass., made a splendid exhibit of the various devices in the electric heating art, which was in charge of Messrs. J. I. Ayer, A. W. Doe and C. W. Richards.

AMERICAN CIRCULAR LOOM COMPANY, Chelsea, Mass., distributed neat little souvenirs. Its representatives included Treasurer A. T. Clark and Mr. T. H. Bibber, of the home office, and Mr. R. B. Corey, of the New York office.

NATIONAL CARBON COMPANY, Cleveland, had a number of its representatives at the Convention, among whom were N. C. Cotabish, sales manager, and Messrs. H. Murray, J. C. Irvine, J. F. Kerlin, F. C. Park and A. D. Spear.

STANLEY ELECTRIC MANUFACTURING COMPANY, Pittsfield, Mass., occupied commodious quarters and had its usual large corps to look after its interests. Among these were Dr. F. A. C. Perrine and Mr. Ray D. Lillibridge.

MUNDER ELECTRIC COMPANY, Springfield, Mass., was ably represented by President C. F. Munder and Mr. C. J. Purdy, manager of the New York office, who interested many of the delegates in the good points of Munder lamps.

TRIUMPH ELECTRIC COMPANY, Cincinnati, Ohio, was represented by Mr. C. A. Cotton.

A number of inquiries were heard for Manager W. H. Jacob, who has been a familiar figure at many of the previous conventions.

THE CONDIT ELECTRICAL MANUFACTURING COMPANY, Boston, was represented by President S. B. Condit, Jr., and F. W. Nason, who explained the features of the Elden circuit-breaker and distributed some very acceptable pocket-knife souvenirs.

THE PETTINGILL-ANDREWS COMPANY, Boston, exhibited a large line of its various specialties. A large force of its representatives was on hand, headed by Mr. C. B. Price. A copy of the Underwriters' Rules in a green leather pocket book was distributed as a souvenir.

THE STERLING MANUFACTURING COMPANY, Warren, Ohio, distributed through Stuart-Howland Company, their New England agents, an attractive souvenir in the shape of a tape measure enclosed in a celluloid case on which was data relative to the Sterling special lamps.

SAWYER-MAN ELECTRIC COMPANY, New York, displayed in public for the first time its "Lumino" lamp. The lamps are of 54 candle-power and were used to light a large candelabra in the main Westinghouse exhibit room. A full line of standard incandescent lamps was also shown by the company.

THE PHELPS COMPANY, Detroit, Mich., was in evidence at the Convention by an exhibit of "Hylo" lamps in charge of Messrs. W. E. Phelps and F. L. DuBroy. "Winking" lamps for sign work and the new "Lazy Man's" lamp were features of the display. The company's other well-known types were shown in great variety.

FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., made a very handsome exhibit in one of the parlors of all of its well-known specialties. The company was largely represented. Its efficient staff included Messrs. J. A. Smith, T. L. Sturgeon, J. C. Lott, F. S. Hunting, J. W. Hilgeman, J. Kent, A. A. Serva and J. O. Spear, Jr.

STUART-HOWLAND COMPANY, Boston, occupied parlors at the Vendome and made an interesting display of electrical specialties. Souvenir whist counters were distributed. Those in charge were Messrs. G. M. Stuart, A. H. Howland, A. E. Payne, C. R. Fish, Huntington Lee, C. B. Wetmore, J. Wilson, W. Merritt and H. De Steese.

THE CROUSE-HINDS COMPANY, Syracuse.—In addition to President H. B. Crouse, Messrs. A. F. Hiller, C. Blanding, F. M. Hawkins and S. S. Grady came on to look after the company's interests at the Convention. The company made no exhibit, but a number of "Harpoon" guy-anchors, which were shown in miniature, received much favorable comment.

THE ALLIS-CHALMERS-BULLOCK interests were looked after by Mr. Arthur Warren, assisted by Messrs. G. H. Berg, H. E. Rundlett, J. R. Jeffrey, E. W. Goldsmith, E. T. Pardee and W. N. Ober. The combined companies occupied handsome quarters on the parlor floor which were decorated with large photographs of notable plants and machines built by the various interests.

THE DUNCAN ELECTRIC MANUFACTURING CO., Lafayette, Ind., exhibited some of the latest types of direct-current indicating wattmeters, a special feature of which is the new visual bearing with threadless jewel post. The company also exhibited switchboard meters in various designs and finishes. The exhibit was in charge of Messrs. Thomas Duncan and William H. Sinks.

THE GENERAL ELECTRIC COMPANY made no exhibit, although it occupied a large parlor. On Friday a number of delegates visited the G. E. shops at Lynn, Mass., where they were accorded an interesting and profitable time. Among the General Electric men present were Messrs. J. R. Lovejoy, E. E. Gilbert, W. C. Fish, C. D. Haskins, E. H. Mullin, C. B. Davis, H. W. Hillman, C. T. Moseman, G. T. Bridgman, J. R. Prentice, A. F. Giles, J. B. Pevear, E. D. Mullen, A. D. Babson, E. E. Peaseley, A. W. Ives, J. S. Butler, P. D. Wagoner, D. R. Bullen, H. L. Monroe, F. G. Vaughan, R. Fleming, F. M. Laxton, J. C. Kalisch, W. J. Hanley, J. Scribner, W. T. Wooley, H. L. Monroe, A. D. Page, G. F. Morrison, W. F. Willcox, T. E. Bibbins, H. H. Crowell, J. P. Felton, F. M. Kimball, S. B. Paine, R. B. Hampson, C. B. Burleigh, J. A. Wilson, H. W. Brown, O. F. Brastow, C. W. Fletcher, A. H. Coffin, M. J. Fitch.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY made an interesting and elaborate display on the ground floor of a number of new appliances used in electric lighting and central station practice. The exhibit was in charge of R. L. Warner. A number of the officials of the company were in attendance, a complete list being as follows: Messrs. F. H. Taylor, Arthur Hartwell, W. H. Whiteside, R. L. Warner, C. B. Humphrey, W. F. Fowler, H. D. Bayne, C. W. Underwood, G. B. Dusinberre, D. E. Manson, Andrew Raeburn, C. C. Chappelle, Y. L. Brinsmade, H. P. Davis, F. F. Rohrer, C. W. Register, J. B. Comstock, Henry Watts, A. Goodby, George W. Pulver, Frank B. Erwin, O. T. Smith, C. E. Skinner, E. E. Arnold, F. E. Conrad, Francis Hodgkinson, J. H. Smith, Edwin Yawger, H. R. Stuart, R. L. Rathbone, C. S. Jennings, C. G. Wilson, S. M. Bramman, F. F. Breed, J. W. Lucas, C. L. Abbott, E. D. Mills, M. H Merrill, G M. Bates, R. S. Brown, F. S. Perry, G. L. Osborne, G. S. Gibbs.

Numerous other manufacturers and supply companies were also in evidence, among whom were the following: Federal Electric Company, Mr. W. H. McLain; Chicago Fuse & Wire Company, Messrs. W. E. Weinsheimer and R. W. Smith; Peerless Electric Company, Mr. A. Dunlop; De Laval Steam Turbine Company, Mr. C. Garrison; Benjamin Electric Manufacturing Company, Mr. B. G. Kodjbanoff; Safety Insulated Wire & Cable Company, Mr. F. B. Parsons; C. H. Whall & Company, Mr. F. R. Whall; Wheeler Reflector Company, Mr. H. C. Hawks; Crescent Gas & Fixture Company, Mr. H. S. Beaman; Kimmey Electric Company, Mr. C. A. Brown; Jandus Electric Company, Mr. E. L. Nash; Kinsman Electric Railway Supply Company, Mr. F. E. Kinsman; Ballou-Hutchins Electric Company, Mr. C. A. Ballou; Washington Carbon Company, Mr. J. S. Crider; Phillips Insulating Wire Company, Mr. A. N. Palmer; D. & W. Fuse Company, Mr. W. S. Sisson; R. D. Wood & Co., Messrs. C. W. Lummis and H. G. H. Tarr; Re-New Lamp Company, Messrs. H. Hastings and G. H. Smith; Tipless Lamp Company, Mr. R. S. Carrick; Crescent Insulating Company, Mr. L. F. Jackson; Magnet Wire Company, Mr. H. Hill; The Wire & Cable Company, Mr. E. F. Sise; Marion Insulated Wire & Rubber Company, Mr. J. L. Lucas; Novelty Electric Company, Mr. C. E. Trump; Emerson Electric Manufacturing Company, Mr. E. L. Barkhouse; Electric Material Company, Mr. A. L. Bosley; Power & Mining Machinery Company, Mr. F. P. Thorp; Warren Arc Light Company, Mr. J. A. Stewart; I. P. Frink, Mr. Frank Stout; Sibley & Pitman, Mr. F. S. Gardner; Adams-Bagnall Electric Company, Mr. G. A. Thomson; Standard Varnish Works, Mr. J. C. Dolph; Lawrence Gas Fixture Company, Mr. C. V. Daiger; Buckeye Engine Company, Mr. A. K. Ashworth; E. B. Latham Company, Mr. E. B. Latham; National Wire Corporation, Mr. F. B. Parsons; Page Electric Company, Messrs. J. P. Coghlin and F. S. Miller; New Britain Machine Company, Mr. R. S. Brown; Independent Incandescent Lamp Company, Mr. W. M. Rothschild; H. B. Camp, Mr. C. C. Baird; American Vitrified Conduit Company, Mr. S. A. Douglas; Wirt Electric Company, Mr. W. J. Thompson; Fred J. Lucey, of F. J. Lucey Company; Sampson & Allen, Mr. A. T. Sampson; T. F. Carey Company, Messrs. Thomas F. Carey and C. H. Currier; Hewes & Phillips Iron Works, Mr. Franklin Phillips; McMichal & Wildman Company, Mr. F. B. Wildman; Ansonia Brass & Copper Company, Messrs. R. A. Cowles and F. H. Sherwood; Nightingale & Childs Company, Mr. E. G. Crosley; Charles A. Schieren & Co., Messrs. G. H. Hamblett and E. A. Usina; American Steel & Wire Company, Messrs. R. K. Sheppard, V. Goldthwaite, F. A. Keyes and A. F. Walker; Gillender & Son, Inc., Mr. W. Croft, Jr.; India Alkali Works, Mr. C. P. Powers; M. K. Kendall & Co., Mr. M. K. Kendall; Packard Electric Company, Canada, Mr. G. C. Rough; White Automobile Company, Mr. T. H. Tucker; J. Wilkinson & Co., Messrs. L. C. Billings and H. L. Slade; Bates & Neilson, Mr. J. Neilson; National Pipe Bending Company, Mr. W. G. Ruggles; M. W. Dunton Company, Mr. F. Chapman; Dwyer Machine Company, Mr. E. F. Dwyer; Potter & Earle, Mr. J. L. Potter; Heine Safety Boiler Company, Mr. E. L. McGregory; New England Machine Company, Mr. F. W. Smith; Macbeth-Evans Glass Company, Messrs. E. S. Briggs and M. B. May; Gamewell Fire Alarm Telegraph Company, Mr. H. E. Stover; Fall River Machine Company, Mr. G. A. Irving; E. J. Electric Insulating Company, Mr. M. H. Stearns; Colonial Electric Company, Mr. W. F. Curtis; W. Frederick Swift & Co., Mr. J. H. Hallberg; Fields-Foulk Company, Mr. C. J. Fields; Standard Paint Company, Mr. L. G. Goodrich; Bryant Electrical Company, Messrs. W. C. Bryant and F. V. Burton; American Brass & Copper Company, Mr. Randolph Osborn; Standard Optical Company; Mr. J. E. Bowker; Alphaduct Manufacturing Company, Mr. Russell Dart; The Dale Company, Mr. John H. Dale; India Rubber & Gutta Percha Insulating Company, Messrs. William M. Habirshaw and James B. Ilson; Bates Advertising Company, Mr. C. D. Marsh; Lynn Incandescent Lamp Company, Mr. Webster Bruce.

OBITUARY.

CHARLES HENRY PLUNKETT, an electrical engineer well known in elevator circles, died June 12 at his mother's home, Hinsdale, Mass., of pulmonary tuberculosis. Mr. Plunkett was born in Hinsdale in 1876 and was educated in the public schools there and the high school at Pittsfield. After graduating from the high school he chose the profession of electrical engineer, and upon completing his studies went directly to the Sprague Elevator Company, New York. He was afterward connected with the Otis Elevator Company and the Marine Engine & Machine Company and had charge of the installation of many important equipments.

WILLIAM WALLACE, of pioneer arc lighting fame, died at Washington recently at the age of 79 years. Mr. Wallace was born in England in 1825, but came to this country when a young man and with his father established the firm of Wallace & Son, at Ansonia, Conn., manufacturers of copper and brass alloys. Becoming associated with Professor Moses G. Farmer, the firm began the manufacture of telegraph wire. At the Centennial Exposition in 1876 Mr. Wallace exhibited the Farmer-Wallace dynamo, and later on, devised the arc lamp with carbon plate electrodes, from which he is best known to the electrical fraternity.

JAMES A. MYERS, president and treasurer of the Robbins & Myers Company, Springfield, Ohio, died of typhoid fever at his home in Springfield on May 27. Mr. Myers was born at Jamestown, Ohio, in 1851, and was educated at the Bowersville Academy. He engaged in business in Springfield in 1876 and two years later became interested with Mr. Robbins in the iron foundry business. In 1889 the two men formed the present Robbins & Myers Company. In 1900 Mr. Robbins retired from the company and Mr. Myers became its president, which office he occupied up to the time of his death. The company entered the electrical manufacturing field in 1896, since which time Mr. Myers has been a vigorous factor in the field and has made a large number of warm friends among the members of the electrical fraternity. He was a very successful business man, the present prominent position of his company being due to his good judgment and energetic management. Mr. Myers leaves a wife and two sons.

JAMES A. MYERS.

PERSONAL.

MR. JOHN G. PHILLIPS, purchasing agent for the Hudson Valley Railway, has been appointed master mechanic of the entire system.

MR. J. C. McQUISTON has been appointed superintendent of the Westinghouse Companies' Publishing Department, with headquarters at East Pittsburg, Pa.

MR. MARK A. REPLOGLE has been retained as chief engineer by the Replogle Governor Works, Akron, Ohio, which will put on the market Mr. Replogle's new differential water wheel governor.

MR. ROBERT McF. DOBLE, the well-known consulting and supervising engineer of San Francisco, has joined the staff of the Abner Doble Company, manufacturer of tangential water wheels.

MR. CHARLES R. GUERTLER, of the Engineering Company of America, is making an examination of the route for the proposed Roanoke & Mt. Airy railway.

MR. EDWARD WESTON received the honorary degree of Doctor of Science from Stevens Institute on the occasion of the commencement exercises held last month.

MR. HIRAM FOLEY has resigned the position of electrician of the Mexican Central Railroad shops at Aguascalientes, Mexico, to return to the United States. Mr. Foley's present address is Peru, Ind.

MR. GEORGE A. DAMON was married on June 8 to Miss Henrietta B. Diller, of Chicago. Mr. Damon is the managing engineer of the Arnold Electric Power Station Company and has a host of friends in the electrical field.

MR. PAUL M. MOWREY has been appointed vice-president of the Engineering Company of America. Mr. Mowrey has been prominently identified with engineering and contracting work since 1888, when he became connected with the Edison Illuminating Company.

MR. RUDOLPH MIEHLING, who has been for some time past New York manager for the Walker Electric Company, of Philadelphia, recently resigned that position to accept the position of sales engineer with the Frank Adam Electric Company, St. Louis, Mo.

MR. LOUIS F. PHILO, for the past six years prominently connected with the Wesco Supply Company, has severed his connection with that company and accepted the position of assistant manager of sales with the Ewing-Merkle Electric Company, St. Louis, Mo.

MR. MASON D. PRATT has established an office at 18 North Third Street, Harrisburg, Pa., for the purpose of engaging in general engineering. Mr. Pratt is prepared to make surveys, plans and specifications, supervise construction of electric railway and power plants, water works plants, etc., and to make examinations of existing plants.

MR. JAMES W. LYONS, who has been an engine salesman with the Allis-Chalmers Company for several years, was recently appointed manager of the newly created power department of that company. Mr. Lyons' headquarters will be at the Chicago office and his department will control the sales of all steam engines, turbine-generator sets, condensers, air compressors and gas engines.

MR. C. C. TYLER has resigned the position of superintendent of works of the Westinghouse Electric & Manufacturing Company to accept the general superintendency of all of the works of the Allis-Chalmers-Bullock interests in the United States. Mr. Tyler's headquarters are at Milwaukee. He is recognized as an expert of high ability in everything pertaining to economical machine shop administration.

MR. B. FRANKLIN HART, JR., who has been associated with Mr. Edwin Burhorn, a well-known contracting engineer, has resigned his position with Mr. Burhorn and established the firm of B. Franklin Hart & Co., for the purpose of manufacturing boilers, tanks and all classes of plate steel construction work. The firm has fully equipped pattern foundry and machine shops in connection with the plate steel shops and is prepared to make castings of all kinds. Its headquarters are at 143 Liberty Street, New York.

TRADE PUBLICATIONS.

FAN MOTORS. Fort Wayne Electric Works.—A well-executed, pocket-size booklet containing illustrations and brief descriptive data of the complete line of Wood fan motors.

THE CURTIS STEAM TURBINE. General Electric Company.—Publication No. 9131, executed in the artistic style characteristic of G. E. literature and containing a very full description in detail of the Curtis turbine.

GAS AND GASOLINE ENGINES. The New Era Gas Engine Company, Dayton, O.—A general catalogue containing illustrations and descriptions of the horizontal gas and gasoline engines built by this company.

INTERIOR ARC LAMPS WITH DIFFUSERS. Fort Wayne Electric Works, Fort Wayne, Ind.—This is bulletin No. 1055, devoted to the Wood direct-current, constant-potential arc lamp equipped with a circular diffuser for interior lighting.

BUFFING AND GRINDING MOTORS. The Holtzer-Cabot Electric Company, Brookline, Mass.—Bulletin No. 307, containing an illustrated description of direct and alternating-current motors having shafts extended to form buffing spindles, and mounted on appropriate base with tool rests.

INTEGRATING WATT HOUR METERS. Duncan Electric Manufacturing Company, Lafayette, Ind.—A twelve-page pamphlet of standard size, containing illustrations and brief descriptions of the various classes of Duncan integrating watt-hour-meters.

MANUFACTURING PLANTS. Westinghouse Electric & Manufacturing Company.—A superbly executed book, 7½ ins. x 9½ ins., containing photographic views of the individual Westinghouse establishments, a complete group of all of them, interior view, and pictures of representative Westinghouse apparatus and installations.

AUTOMATIC SELF-CONTAINED ENGINES. Chandler & Taylor Company, Indianapolis, Ind.—A catalogue of standard size, designated "Series E-1," and containing a detailed illustrated description of the new simple and compound horizontal engines brought out by this company for electric light and power service and other exacting classes of work.

ENGINES AND BOILERS. The James Leffel Co., Springfield, Ohio.—This is a handsomely executed catalogue of standard dimensions, opening endwise, and containing a detailed and profusely illustrated description of the Leffel throttling and automatic horizontal engines and horizontal return tubular boiler of the internally fired and ordinary types.

COOPER-CORLISS ENGINES. The C. & G. Cooper Company, Mt. Vernon, Ohio.—A collection of artistic half-tone engravings on heavy plate paper, illustrating the various types of Cooper-Corliss engines and some notable installations of them. Two of the engravings are of large size and sufficiently handsome to amply justify framing. These show three 250-h.p. Cooper-Corliss engines direct-connected to alternators in the power house of the Aurora, Elgin & Chicago Railway Company and a 1200-h.p. engine driving a direct-current generator in the power house of the National Cash Register Company, Dayton, Ohio.

BUSINESS NEWS.

THE ELECTRIC STORAGE BATTERY COMPANY has taken a residence at 4472 Forest Park Boulevard, St. Louis, for the use of the members of its staff attending the Exposition.

THE F. BISSELL COMPANY, Toledo, Ohio, calls the attention of the trade to the fact that it not only builds special switchboards for theaters, but also manufactures a special switch for theater service.

B. F. STURTEVANT COMPANY, Boston, Mass., announces that the removal of its plant from Jamaica Plain to the new works at Hyde Park, Mass., has been completed and the company is in position to handle all orders promptly.

GEORGE W. LORD COMPANY, Philadelphia, Pa., manufacturer of Lord boiler compounds, is distributing copies of an interesting photograph which shows a shipment of Lord's boiler compound in transit on crude wagons pushed and pulled by East Indian laborers in Madras.

ENGINEERING COMPANY OF AMERICA, New York, which has heretofore been engaged in purely professional work, has embarked in general engineering, construction and contract work in addition and is prepared to undertake all kinds of general contracting.

ABNER DOBLE COMPANY, San Francisco, manufacturer of tangential water wheels has organized a consulting engineering department and is prepared to take charge of the design and construction of power plants, pumping plants and other engineering work.

THE LUNKENHEIMER COMPANY, Cincinnati, on June 16 served a luncheon at its new manufacturing plant to delegates of the Ohio State Convention of the National Association of Steam Engineers, who visited the plant on invitation and were shown through the entire works after luncheon.

THE LAGONDA MANUFACTURING COMPANY, Springfield, Ohio, has an attractive exhibit in the Steam, Fuel and Gas Building at the St. Louis Exposition, consisting of a display of tube cleaners and other boiler-room specialties, located directly in front of the line of boilers exhibited in the building mentioned.

CROCKER-WHEELER COMPANY, Ampere, N. J., announces that the well-known firm of Dodge & Day has been retained by the company for the purpose of giving its customers the benefit of the firm's wide experience and large collection of data accumulated during several years of active work in modernizing manufacturing establishments. No charge is made to Crocker-Wheeler customers for this expert service.

CROUSE-HINDS COMPANY, Syracuse, N. Y., informs us that at the Elks' Convention to be held in Cincinnati, July 8 to 25, there will be used nearly 30,000 Norbitt porcelain temporary sockets for decorative purposes, illuminating the streets for a distance of 37 blocks. More than 500 Norbitt sockets will also be used in making a huge illuminated flag to be hung over Government Square.

A CORRECTION.—On page 317 of our June number the Standard Underground Cable Company, of Pittsburg, was erroneously referred to as the "Stanley" Underground Cable Company in an item describing the joint exhibit of this company and the McRoy Clay Works at the St. Louis Exposition. As the Standard Underground Cable Company is well known in electrical circles all over the world, and as there is no such concern as the "Stanley" Underground Cable Company, the error probably caused no confusion, but it was, nevertheless, regrettable.

RHODE ISLAND ELECTROMOBILE COMPANY, Providence, R. I., recently made a trial run with forty cells of its automobile battery in an old motor vehicle over the roads between Providence, R. I., and Boston, Mass., the results of which were extremely satisfactory. On level roads the discharge averaged 30 amperes and on the hills between Pawtucket and Boston it ranged from 60 to 70 amperes. The weight of each cell was 29 pounds and the maximum ability 200 ampere-hours. The run to Boston and an additional run of about 30 miles around the city was made on a single charge.

AUTOMATIC ELECTRIC COMPANY, Chicago, has recently received important contracts, among which may be mentioned two for automatic equipments to replace manual systems in the cities of Battle Creek, Mich., and Van Wert, Ohio. The Battle Creek exchange is owned by the Citizens' Telephone Company, of Grand Rapids, who substituted automatic apparatus last winter for the manual exchange in Grand Rapids. The Battle Creek exchange is to have an immediate capacity of 1000 instruments, with an ultimate capacity of 10,000 The Van Wert exchange is to have an immediate installation of 925, with an ultimate capacity of 10,000. The company extends a cordial invitation to members of the electrical fraternity to visit its headquarters at Section 24, Palace of Electricity, St. Louis Exposition.

CENTRAL STATION NEWS

ALABAMA.

WYLAM.—The question of erecting an electric light plant and water works is being discussed here.

SYLACAUGA.—The citizens recently voted to issue $20,000 in bonds for the construction of an electric light plant and water works.

BIRMINGHAM.—It is understood that a power plant is proposed, but the plans concerning the size and details of construction are not yet matured.

JASPER.—A franchise for the operation of an electric railway has just been granted to the Jasper Water, Light & Power Company, of which Mr. J. M. Crawford is manager.

ATHENS.—The city authorities are contemplating the erection of a larger plant, as the present one is not capable of developing sufficient power to meet the demands. Mr. Samuel White is superintendent.

MONTGOMERY.—The Citizens' Light, Heat & Power Company recently announced the completion of its plant which went into operation the early part of June. The machinery is all in duplicate, thus insuring reliable and efficient operation.

OPELIKA.—The Opelika Railway, Light & Power Company was recently organized with a capital of $300,000. The following officers have been elected: President, Mr. J. B. Green; first vice-president, Mr. Rush Taylor; second vice-president, Mr. Bartow Smith; secretary and treasurer, Mr. W. C. Robinson. It is proposed to construct an electric railway from this city to Auburn and furnish lighting and power current for both places.

ALASKA.

SITKA.—It is the intention of the W. P. Mills Company to install an electric light plant in this city.

SEWARD.—Mr. Albert Dickinson, Mr. George Bohns, Mr. Harry Kennedy and Mr. W. E. Catzdanner have secured a franchise for the construction and operation of an electric light plant at this place. The active work of construction of a 1700-light plant is now under way.

ARIZONA.

NOGALES.—Mr. V. P. Maloney is now chief engineer of the Nogales Electric Light, Ice & Water Company. The company also furnishes lighting current to the town of Sonora, Mexico.

FLAGSTAFF.—The Flagstaff Electric Light Company expects within the next few months to add to its equipment a new generator, engine and boiler, in order to be able to supply current for street lighting purposes. Mr. G. T. Herrington is manager of the company.

ARKANSAS.

PARAGOULD.—Mr. P. D. Roe has been made manager of the Crystal Ice Company, successor to the Paragould Electric Light Company.

PINE BLUFF.—The Citizens' Light & Transit Company is considering placing an order for a 250-kw. or 300-kw. alternator for its plant.

SILOAM SPRINGS.—The municipal electric light plant is extending its lines and expects to make improvements which will double the capacity of the plant.

LEWISVILLE.—The Lewisville Light & Water Company has been incorporated for the purpose of constructing and operating an electric light plant, ice factory, steam laundry and water works. The company is capitalized at $25,000; Mr. E. B. Daniel is president, and Mr. G. W. Dobson, secretary.

FAYETTEVILLE.—Bids are wanted for a two-Phase, 120-kw. alternator to be operated either by steam turbine or direct-connected engine. It is understood that a day circuit both for light and power will be added, and other improvements are being considered. Mr. F. W. Fratt, of Oklahoma City, O. T., is owner of the plant. Mr. J. W. McLendon is superintendent.

DE QUEEN.—The following-named gentlemen are officers of the De Queen Light, Ice & Cold Storage Company: Mr. J. S. Lake, president; Mr. G. B. Pride, vice-president; Mr. George T. Scott, secretary and treasurer; Mr. A. P. Cone, manager; Mr. Elmer Mellott, chief engineer, and Mr. E. F. Chaffin, chief electrician.

BRINKLEY.—The Citizens' Light & Power Company is now known as the Farrell Light, Heat & Water Company. The company has a capital stock of $50,000, fully paid in, and has recently erected a new plant. It is officered as follows: Mr. J. J. Farrell, president; Mr. M. A. Farrell, secretary and treasurer; Mr. A. Rutherford, superintendent; Mr. W. Matthews, chief electrician.

MALVERN.—Some improvements are contemplated by C. W. Turner & Co., proprietors of the electric light plant, formerly known as the Malvern Light & Power Company. These will include a new dynamo and a new boiler. The following are the officers of the Company: President, Mr. C. W. Turner; vice-president and secretary, Mr. Lloyd Turner; treasurer and manager, Mr. C. W. Turner, Jr.; chief engineer and electrician, Mr. Joseph Brown.

CALIFORNIA.

PALO ALTO.—Mr. W. S. Barnhisel has been elected chief electrician for the municipal plant of the Palo Alto Company.

SEBASTOPOL.—Mr. G. W. Swain has been granted a franchise for the construction and operation of an electric light plant.

SPRINGVILLE.—The Globe Light & Power Company proposes erecting a new power plant between this city and the club house.

OXNARD.—The Oxnard Light & Power Company is preparing plans for an electric power house and plant. Major A. J. Driffill is president of the company.

SANTA ROSA.—The stock of the Merchants' Light Company has been purchased by the California Gas & Electric Company and its properties and business are now owned by the latter company.

WATSONVILLE.—The Watsonville Light & Power Company has been incorporated. Among the incorporators are Messrs. Fish M. Ray, Oakland; Joseph C. Love, Berkeley, and David H. Foote, San Francisco.

OAKLAND.—It has been recommended by the Street Lighting Committee that the contract for lighting the streets of Oakland for the ensuing year be given to the Oakland Gas, Light & Heat Company at $7.25 per month.

MONTEREY.—Mr. C. W. Allen is now manager of the Monterey Gas & Electric Company. The company is a consolidation of the Salinas Water, Light & Power Company and the Monterey-Pacific Grove Railway Company.

SAN FRANCISCO.—The Mt. Lassen Water Power Company has been incorporated with a capital of $50,000, by Messrs. Archibald Barnard, L. M. Robbins, A. G. Sheath, and others. The headquarters of the company will be in this city.

TUOLUMNE.—Articles of incorporation have been filed by the Central California Electric Company for the purpose of operating in Tuolumne County. The capital stock is placed at $500,000. Messrs. J. L. Gibbs and J. E. Conde are the incorporators.

YREKA.—The Siskiyou Electric Power Company has purchased the plant and business of the Aetna Electric Light Company and is now engaged in extending the main power line from Fort Jones through Greenview to Aetna, a distance of 12 miles.

BLUE LAKE.—Mr. C. D. G. Miller, president of the Eureka Lighting Company, accompanied by parties from Los Angeles and San Francisco, recently made a trip to the south fork of Trinity River with a view to locating a site upon which to erect a large power plant.

SAN BERNARDINO.—The Arrowhead Construction Company, which is building a large dam near this place, has just let the contract for the concrete core wall. The completion of this dam will make it possible to develop several thousand horse-power, which will be used for electrical purposes.

SAN FRANCISCO.—The Mutual Electric Light Company, with officers at 627 Howard Street, recently called a meeting of its stockholders to vote an issue of $400,000 in bonds, $250,000 to be sold for improvements and the remaining $150,000 to be held in the treasury until such time as it is needed.

SANTA MARIA.—The Santa Maria Power & Lighting Company has been incorporated with a capital of $50,000 to supply electric light and power to Santa Maria. The directors are Messrs. H. T. Duff, W. F. Gibbs, R. H. Pallard and F. C. Armstrong, of Los Angeles, and Mr. B. E. Page, of Pasadena.

LOS ANGELES.—The Los Angeles Lighting Company and the Los Angeles Electric Company have been consolidated by the Pacific Lighting Company, to reduce operating expenses, under the name of the Los Angeles Gas & Electric Company, which was recently organized with an authorized capital stock of $5,000,000, of which $4,000,000 has been issued.

NEVADA CITY.—The Nevada County Electric Power Company was recently absorbed by the California Central Gas & Electric Company, which, in turn, is now controlled by the California Gas & Electric Company. Mr John Martin is president; Mr. John A. Brown, vice-president and general manager; Mr. C. W. Conlisk, secretary, and Mr. R. M. Hofaling, treasurer.

LOS ANGELES.—The large engine in the Inglewood plant of the Edison Electric Light Company recently tore its crank boxes to pieces, leaving Long Beach in darkness until ten o'clock, when power from the Santa Monica plant was cut in. The engine was badly wrecked and power will be secured from the Pacific Electric Company until repairs at Inglewood are completed.

MENTONE.—The power plant of the Mentone Power Company, a branch of Huntington's Pacific Light & Power Company, is nearing completion and it is expected that within another month it will be in operation. The power house itself has been completed and part of the machinery is being installed; the transmission line to Los Angeles is also complete. The cost of the plant is estimated at $25,000. Nearly all the power furnished will be utilized by the Pasadena and Los Angeles trolley cars.

TULARE.—The electric plant at this point is a sub-station of the Mt. Whitney Power Company, whose main station is located at Visalia, a few miles north of here. Mr. Fred Hamilton is superintendent of the Tulare plant. Mr. Frank O. Smallwood, who has for a number of years served as engineer here, has been promoted to a position in the new main power house on the Kaweah River. Mr. Ray Holmes succeeds him in the sub-station.

FERN.—The new power plant of the Northern California Power Company on Cow Creek, near here, is nearing completion. One of the 2000-h.p. generators has been installed; the four-mile flume and ditch, taking water from Cow Creek, are finished, and work is being pushed on the three-acre reservoir at the head of the pipe line. The plant will be capable of developing 4000 horse-power, which will supplement the current now generated at the Shingletown plant of the company. The two plants are connected with all the power lines extending over Shasta, Tehama and Glenn Counties.

SAN FRANCISCO.—Mr. Harry L. Shannon, of this city, who is promoting a new electric power

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

system in Shasta County, hopes to have the first 1500-h.p. unit in operation by January 1. The ditches, flumes and pipe and pole lines will have a capacity of 3000 horse-power, and later, as the market justifies, the second unit of 1500 horse-power will be installed. Water will be diverted from Hat Creek just below Mt. Lassen and conveyed thence by ditch and flume, a distance of five or six miles, to Bear Creek. The pipe line will then be extended down Bear Creek to a point in the neighborhood of Bear Creek Falls. Here a fall of 1500 feet can be obtained in a distance of 6000 feet, developing 5000 horse-power.

SAN FRANCISCO.—More than half of the 500,000 shares of the North Mountain Power Company, which was incorporated for the purpose of developing an electrical power plant on the Smith River to supply Eureka and the adjacent towns, has been subscribed, and work has begun. The necessary machinery, wires and insulators have been ordered, and the water rights and ditches of Compagnie Francaise, a French mining company, have been purchased. Immediately upon completion of the initial line into Eureka, work will begin upon the company's water rights on the south fork of the Trinity in Trinity County and upon all the branches of the Smith in Del Norte County. The company was incorporated in 1902 with a capitalization of $500,000, the principal stockholders being Messrs. John H. Vance and William Carson, of Eureka, and Messrs. John L. Koster, Fred J. Koster, D. G. Scofield, W. H. Metson and Robert J. Tyson, of San Francisco. The office of secretary, Mr. Robert J. Tyson, has been established at 18 California Street.

COLORADO.

GOLDEN.—Mr. R. R. Morrill is now chief engineer of the Golden Illuminating Company.

LAMAR.—Mr. F. A. Dowler is chief engineer and electrician of the Lamar Electric Company.

GEORGETOWN.—Mr. L. C. Coggshall has been made chief engineer for the United Light & Power Company.

SALIDA.—Mr. J. Seligman has been elected president of the Edison Electric Light Company of this place.

MONTE VISTA.—Mr. N. H. Chapman is president and manager of the Monte Vista Electric & Gas Light Company and Mr. T. D. Shilling is now chief engineer.

DENVER.—The Colorado Power & Irrigation Company has secured a location on Grand River for the erection of two power plants, a main plant capable of developing 15,000 horse-power and a small auxiliary plant of 5000 horse-power. Work has been commenced on the site, but it will probably be a year before the plants are ready for operation and no contracts for machinery have been let as yet. Current will be transmitted 100 miles for mining and lighting purposes, metallurgical processes and irrigation.

CAUM CITY.—The Colorado Electric Power Company, which a year or two ago bought the plant and property of the Caum City Electric Light & Power Company, is now operating two sub-stations in the Cripple Creek district, supplying power to the mines of Cripple Creek and Independence. The company is officered as follows: Mr. D. V. Donaldson, president; Mr. J. H. Lenet, vice-president; Mr. Walter Scott, secretary; Mr. J. V. Hayes, treasurer, all of Colorado Springs; Mr. William T. Wallace, Caum City, manager and superintendent, and Mr. O. J. Rundahl, chief engineer.

CONNECTICUT.

THOMASTON.—The work of excavating for the new electric light plant has begun. The main building will be 71 feet long by 40 feet wide.

STAMFORD.—Mr. G. B. Leland, formerly with the Norwich Gas & Electric Company, has assumed the management of the Stamford Gas & Electric Company, of this city.

WATERBURY.—The New Milford Power Company, which transmits electric power from its plant at Bull's Bridge to this city for consumption by the Connecticut Railway & Lighting Company, has found it necessary to substitute porcelain for all the glass insulators on the double line of aluminum wires. Much more satisfactory results are now obtained.

CANAAN.—Lawyer J. Henry Roraback, of this town, representing New Haven capitalists, has been securing options on water-power sites on the Konapot River, which is located a short distance across the state line in Massachusetts. It is proposed to erect a large power plant for the generaiton and transmission of electricity for lighting purposes in this city, Norfolk and other Connecticut towns.

NORWICH.—Mr. Francis S. Thayer, formerly superintendent of the Westerly Gas & Electric Light Company, Westerly, R. I., has been appointed superintendent of the Norwich municipal light plant. Mr. Thayer is 37 years of age. For thirteen years he was with the Narragansett Electric Company, nine years of which time he was superintendent of that company's gas and electric plants at Warren and Bristol. He is succeeded at Westerly by Mr. F. N. Clark, who has been connected with the plant there for the past seven years.

HARTFORD.—The Hartford Electric Light Company has secured the contract for lighting the city at $70 per lamp per year for a term of five years. The company has leased a tract of land on the Connecticut River front at what is known as Dutch Point, upon which a new power plant will be erected to supersede the present plant on Pearl Street. As the latter is some distance from the river, it is expected that a considerable saving in transportation, water supply and other factors in the operation of the plant will be effected. Much of the equipment at the old plant will be transferred to the new site.

FLORIDA.

ARCADIA.—The Arcadia Electric Light, Ice & Telephone Company is arranging to put its arc lights on a separate circuit.

JACKSONVILLE.—The contract for the 500-kw. turbine generator, to be installed in the municipal lighting plant, has been awarded.

BRAIDENTOWN.—The Manatee Light & Traction Company is preparing to install a series alternating-current arc system. The plant is superintended by Mr. H. G. Hare.

KISSIMEE.—Of the $17,000 bonds recently voted by the citizens, $7000 is to be expended in improvements to the electric light plant, with a view to increasing its capacity. Orders for part of the equipment have already been placed.

TAMPA.—Mr. H. Stuart Pratt has been made treasurer of the Tampa Electric Company; Mr. G. W. Wells is manager, and Mr. F. E. Fletcher, superintendent. The company is considering the advisability of increasing its capital stock by the amount of $100,000.

MONTICELLO.—The power house of the electric plant, owned and operated by Mr. J. M. Henry, of this city, burned down some time ago and has never been rebuilt. The town is greatly in need of a plant for furnishing street lights, and it is thought that the council will shortly take under consideration the erection of a plant for this purpose.

KEY WEST.—The consolidation of the Key West Electric Light Company and the Electric Light & Power Company, which had been rumored for some time, has become an established fact. New machinery has been ordered for the plant of the Key West company, which will continue to furnish lighting and power current, while the other plant will be operated for the manufacture of ice.

GEORGIA.

CARROLLTON.—Mr. Charles Coats is now chief engineer for the Carrollton Electric Company.

CAMILLA.—Mr. J. E. Bishop is chief electrician for the Mitchell County Fertilizing Company, which has the city lighting contract for the town.

TIFTON.—The Tifton Ice & Power Company states that it intends to install a larger engine and dynamo in its plant. Mr. G. M. Roberts is manager for the company.

WASHINGTON.—The city authorities are considering the purchase of a 150-kw. two-phase generator for the lighting plant, and will probably install an electric pump at the water works.

CARROLLTON.—The citizens voted a couple of weeks ago to issue $45,000 in bonds for water works, a sewerage system and an electric light plant.

MILLEDGEVILLE.—Mr. Charles F. Howe, manager of the Oconee Electric Light & Power Company, writes that the company is contemplating improvements which will cost from $500,000 to $750,000.

BARNESVILLE.—A charter for the Flint River Power Company has been applied for by Messrs. G. E. Strickland, J. W. Strickland and associates, for the purpose of developing the property at Flat Shoals on Flint River, from which 5000 horse-power may be obtained.

GRIFFIN.—The City Council is considering the issue of $100,000 in bonds, $40,000 of which will be used for improvements to the lighting plant and water works, the remaining $60,000 to be expended in the installation of a sanitary sewerage system. Mr. J. W. Hammond is superintendent of the electric light plant.

ALBANY.—The City Council of Albany has under consideration a contract with the Albany Power & Manufacturing Company for the purchase of 300 electrical horse-power for a term of ten years for use in running the city's electric light plant and water works. If this contract is ratified, the Albany Power & Manufacturing Company will develop its water power on Muckafoonee Creek two miles north of the city, where it expects to obtain 2300 horse-power.

IDAHO.

BOISE.—Bids have been requested for lighting the city streets and buildings for a period of five years after August 1, this year.

GREER.—The dam and flume of the Lolo Creek Power Company, which was built at a cost of $25,000, was recently washed away by high water, entailing a loss of $10,000. The plant furnished electricity for a lighting plant and mills at Nez Perce. The damage will be repaired as soon as possible.

BOISE.—The capital stock of the Capital Electric Light, Motor & Gas Company is owned by the Boise-Payette River Electric Power Company and the power is all generated by that company at its water-power generating station at Horseshoe Bend on the Payette River, being delivered to the local company at its sub-station in Boise. Mr. O. E. Freeman is superintendent of the plant. The equipment at the generating station consists of two 500-kw. two-phase 200-volt 60-cycle Westinghouse generators. Current is transmitted 22 miles over a three-phase circuit at 22,000 volts, and distributed by means of Y-connected step-down transformers giving 2300 volts and distribution transformers, Y-connected, giving 115 volts.

ILLINOIS.

PANA.—The City Council recently called for bids for lighting the city requiring about 83 arc lights.

GOLCONDA.—A franchise has been granted for an electric light plant, to cost about $4000, of which Mr. J. O. Williamson is to be the manager.

ST. CHARLES.—The municipal electric light plant equipment will probably be increased this summer by the addition of a new Corliss engine and a generator.

LITCHFIELD.—Mr. David David, Mr. William La Force and Mr. Jacob J. Frey recently incorporated the United Gas & Electric Company with a capital stock of $100,000.

GALESBURG.—The work of constructing the large power house for the McKinley syndicate has been commenced. The building, which is to be 125x100 feet, will cost about $200,000.

KANKAKEE.—The Kankakee Electric Light Company will erect a concrete-steel dam across the Kankakee River this summer. Material for the dam is being delivered and active work on the construction will begin shortly. The cost is estimated at about $20,000.

OLNEY.—The officers of the Olney Electric Light & Power Company are: President, Mr. Aden

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

Knoph; vice-president, Mr. W. H. Curnays; secretary, Mr. H. C. Hughes, treasurer, Mr. H. E. Hughes; superintendent, Mr. J. G. Hughes; manager and chief engineer, Mr. E. S. Hughes, and chief electrician, Mr. J. S. Hughes.

KANSAS.—The village lighting plant is erecting new poles and stringing new wires.

ROCKFORD.—The village lighting plant is erecting new poles and stringing new wires.

AMBOY.—The plant of the Amboy Lighting & Power Company is now in charge of Mr. W. A. Green as manager.

COLCHESTER.—A new engine is being installed in the plant of the Colchester Electric Light & Power Company.

OREGON.—Mr. W. L. Taylor is superintendent and chief electrician of the Oregon Electric Light & Power Company's plant.

TOLUCA.—The position of chief electrician for the Toluca Electric Light & Gas Company is now held by Mr. C. J. Walker.

ROSSVILLE.—Mr. Ezra Smock is now occupying the joint position of chief engineer and electrician of the electric light plant here.

ROCKFORD.—It is understood to be the intention of the Central Heat & Power Company to install a new electric plant this summer.

METROPOLIS.—Mr. William Gains is now chief engineer of the city electric light plant. A new 150-h.p. boiler is to be installed at the plant shortly.

QUINCY.—Plans have been perfected by the Quincy Gas & Electric Company requiring an expenditure of $50,000 for improvements during the coming summer.

QUINCY.—The Independent Light & Power Company will increase the capacity of its plant by adding another unit consisting of a 1200-h.p. engine and a large generator.

PAXTON.—The Paxton Electric Company was recently reorganized, but the officers have not yet been named. Mr. J. H. Preston is manager and chief electrician for the plant.

ALTONA.—The electric light plant formerly owned by Johnson & Hogg is now owned and operated by Mr. A. H. Johnson. Mr. Johnson superintends the plant personally.

LE ROY.—Mr. Morrell Tomlin, of this city, is now president and treasurer of the Le Roy Electric Light, Power & Heating Company. The company has the city lighting contract, which includes 25 arc lamps of 2000 candle-power.

CHICAGO HEIGHTS.—The Calumet & Harvey Lighting Company is a consolidation of the Calumet Lighting Company and the Harvey Illuminating Company. Mr. A. E. Walden is superintendent.

DANVILLE.—Mr. T. B. Macaulay has succeeded Mr. G. F. Duncan as vice-president and treasurer of the Danville Street Railway & Light Company, and Mr. Theo. Tillotson is chief engineer, succeeding Mr. C. L. Harry.

GALESBURG.—The work of laying the foundation for the new power house of the Galesburg Electric Motor & Power Company has commenced. The building itself will be constructed of brick and steel; orders for the machinery and other equipment have all been placed, and it is expected that the plant will be in operation about the 1st of September.

CHICAGO.—Edward Bruce Chandler died the morning of June 6 at his residence, 2512 Indiana Avenue, this city. He was born in Hartford, N. Y., in 1838. In 1858 he came to Illinois, being located at Springfield and Rock Island in the employ of the telegraph department of the Rock Island Railroad. Ten years later he came to Chicago to engage in the electrical business. Mr. Chandler was the first city electrician and held that position at the time of the fire of 1871 and for several years afterward. He was graduated from the University of Michigan, and was a member of the Beta Theta Pi Fraternity, of Chevalier Bayard Commandery, and of the Calumet Club.

INDIANA.

MT. VERNON.—The council is considering the question of constructing an electric light plant.

GOODLAND.—Mr. G. O. Thorpe is now superintendent of the Goodland electric lighting plant.

LINTON.—Mr. A. J. Todd is now superintendent of the city electric light plant.

DECATUR.—The equipment of the Decatur city lighting plant is to be increased by the addition of a 300-h.p. Corliss engine.

VEVAY.—Mr. Charles Holcroft is now manager of the Vevay Electric Light & Water Works and Mr. Peter Leep is chief electrician.

KNIGHTSTOWN.—The town authorities expect shortly to install a producer and substitute a gas engine for the present steam engine and boiler.

MUNCIE.—The Muncie Electric Light & Steam Heating Company is making preparations for the enlargement of its plant for furnishing steam heat.

CLINTON.—Mr. U. G. Wright is now secretary and manager of the Clinton Electric Light & Power Company, and the position of superintendent is filled by Mr. C. M. Poor, Jr.

NEW HAVEN.—All bids received by the Town Board for the construction of an electric light plant here have been rejected. New bids will be advertised for at once.

MONTICELLO.—Mr. L. M. Barnes is now proprietor and manager of the electric light plant formerly operated by Van Alstyne & Son. Mr. E. E. Van Alstyne is superintendent of the plant.

ENGLISH.—The English Light Company is understood to be owned by the Naylor Clark Handle Company. The plant has an ultimate capacity of 600 lights, but is carrying only 450 at present. Mr. J. F. Jones is superintendent.

MOORESVILLE.—The Public Service Company is advertising for bids for the construction of the power house for the water works and electric light plant, and states that the plans and specifications are ready for distribution among applicants.

GREENSBURG.—The Greensburg Gas Light Company has changed its name to the Greensburg Gas & Electric Company and increased its capital stock $30,000. The company will erect a plant and furnish electricity for lighting and power purposes in Greensburg.

ELKHART.—The St. Joseph & Elkhart Power Company contemplates important and extensive improvements, among which will be the extension of its system to Goshen, Laporte, Wakarua and Syracuse. The capital stock of the company has been increased from $50,000 to $250,000.

MT. VERNON.—The Mt. Vernon Electric Light & Power Company was recently incorporated with a capital of $5000. The directors are: Messrs. Jesse H. Purdy, George E. Hoffmaister, Harry B. Rhine and others. It is understood that bids for the construction of a plant will soon be asked for.

RICHMOND.—The following are the present officers of the Light, Heat & Power Company: Mr. R. S. Storrs, New York, president; Mr. J. W. Roney, secretary, treasurer and manager; Mr. James Abbott, New York, assistant secretary and treasurer; Mr. E. E. Witherby, New York, vice-president; Mr. B. C. Fowler, superintendent.

BOONEVILLE.—The City Light & Power Company has been awarded the city lighting contract and will push the work on its new plant as rapidly as possible. The contract, as accepted, is a liberal one in that it gives the city complete control, thus obviating the possibility of excessive rates in the future; the city also reserves the right to lease or purchase the plant at its option.

INDIANAPOLIS.—The city has just made a new contract with the Indianapolis Light & Power Company, by which it is entitled to 262 additional lights. The lamps will be placed as soon as it can be determined where they will do the most good. It is also the intention of the board to replace a number of the vapor lamps now in use with 50-c.p. incandescent lights. The vapor lamps have given considerable trouble by going out long before daylight and it has been decided to gradually replace them with incandescents.

INDIANAPOLIS.—The Merchants' Heat & Light Company is contemplating improvements and enlargements, by means of which the capacity of its plant at New Jersey and Pearl Streets will be increased 150 per cent. The cost of the proposed changes is estimated at $250,000 or $300,000. The present power house will be doubled in size and the new equipment will include additional boilers of 2500 horse-power capacity, equipped with chain grates, and two new 1500-h.p. Westinghouse turbine engines. Mr. James B. Nelson is manager and Mr. A. E. Durham superintendent of the company.

FORT WAYNE.—The sale of the plant and property of the Fort Wayne Electric Light & Power Company to Mr. J. W. Mayer, of Buffalo, and other eastern capitalists, was effected recently in consideration of $500,000. It is probable that in the near future the power and light company will be consolidated with the traction interests of the Fort Wayne & Wabash Valley lines. Mr. Mayer, who is also interested in the Lima, Ohio, Electric Railway & Light Company, and Mr. Charles W. Warner, of New York City, are now in the city taking over the affairs of the light and power company. It is understood that Mr. Charles G. Guild will be retained as manager.

WABASH.—The Wabash Water & Light Company has filed articles of incorporation with a capital stock of $160,000. The purpose of the company is to take over the plants of the Wabash Water Company and the Wabash Electric Light Company. The two former companies were owned by the First National Bank of New York, and for the past few years both plants have been managed jointly by Mr. Thomas W. McNamee, of this city, as superintendent. The company's charter is granted for a period of fifty years. The stockholders are: Messrs. Edmund LeB. Gardner, Ridgewood, N. J.; Whitney Conant, Paterson, N. J.; W. G. Shaw, Montclair, N. J.; Thomas W. McNamee, and Thomas McNamee; these constitute the board of directors. Mr. Thomas W. McNamee will continue in his position of superintendent. The plant has been recently enlarged and improved, and the company has no bonded debt.

INDIAN TERRITORY.

CHICKASHA.—The Chickasha Electric Light & Power Company has increased its capital stock to $45,000. Mr. James W. Hackaday is manager of the company.

PAULS VALLEY.—During a recent storm, fire was started in the electric plant owned by Thompson Brothers, almost totally destroying the plant. The loss is covered by insurance.

IOWA.

VILLISCA.—Mr. A. J. Jackson has been made chief engineer of the Villisca Electric Company.

IOWA CITY.—Mr. J. E. Tuttle is now superintendent of the Iowa City Electric Light Company.

IOWA CITY.—The J. F. Hill Electric Company, it is said, contemplates installing an electric light plant.

WILTON JUNCTION.—The citizens recently voted to issue $5250 in bonds for improvements at the electric light plant.

ALGONA.—The improvement of the electric light plant equipment by the addition of an engine and boiler is being discussed by the Countil.

WEST POINT.—The City Council is interested in the establishment of an electric lighting plant to the extent of securing estimates of the probable cost.

CENTERVILLE.—Mr. T. P. Shonty, Chicago, is now vice-president of the Citizens' Electric Light & Gas Company, and Mr. George Gawling has been made chief engineer.

BURLINGTON.—The Merchants' Light & Power Company was recently incorporated. The company will erect an electric light plant here with an initial capacity of 20,000 lights.

FORT MADISON.—The franchises recently granted to Mr. F. C. Wood for an electric light plant, an interurban railway system and a gas plant have been purchased, it is said, by Mr. Samuel Atlee.

LARNED.—Mr. C. W. Smith, proprietor of the Larned electric light plant, which has been supplying the city with light heretofore on a midnight schedule, proposes to make the necessary changes at his plant to enable him to operate on an all-night basis.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

MARION.—The contract of the Marion Light, Heat & Power Company for city lighting is about to expire and a new one is now under consideration. Mr. G. W. Toms is president and manager of the company; Mr. C. O. Ingersoll is secretary, and Mr. C. L. De Wald, chief engineer.

NEVADA.—Several improvements have been in progress at the plant of the Nevada Electric Light Company. An additional engine of 225 horsepower, with a dynamo of corresponding size, has been installed, necessitating the enlargement of the building. Concrete foundations have been put in for all of the machinery. The installation of the new machines provides a double equipment for the plant, insuring satisfactory service.

KANSAS.

CLAY CENTER.—Mr. F. A. Johnson is now general superintendent of the Clay Center Electric Light & Power Plant.

GARNETT.—Mr. Henry Myer is now manager of the Garnett Electric Light Company, which has the city lighting contract.

BLUE RAPIDS.—Mr. C. A. Axtell is chief electrician of the Electric Plaster Company, which has the lighting contract for the city.

BURLINGAME.—Mr. M. L. Morrison has succeeded Mr. E. H. Standard as manager and superintendent of the city electric light plant.

VALLEY FALLS.—Local reports state that the plant of the Roth Electric Light Company was seriously damaged by the spring floods and has since been idle. Mr. Roth, who operated the plant, has left the city and it is doubtful when the plant will be again in operation.

ARKANSAS CITY.—The officers of the Arkansas City Gas & Electric Company are as follows: Mr. W. M. Sleeth, president; Mr. H. P. Farrar, vice-president; Mr. Howard Ross, secretary; Mr. A. A. Newman, treasurer; Mr. J. H. Clay, superintendent. The company is supplying the city with current for thirty arc lights and also furnishes electricity for 75 commercial arc lights and 1500 incandescent lamps.

KENTUCKY.

DANVILLE.—The City Council has decided to receive bids for an electric light franchise.

ELIZABETHTOWN.—Mr. J. C. Stonfield is now chief engineer of the Elizabethtown Electric Light Company.

PINEVILLE.—Articles of incorporation have been filed by the Pineville Light & Ice Company, with a capital stock of $25,000.

ASHLAND.—The Ashland Electric Light & Power Company has been merged with the Camden Interstate Railway Company.

CALDWELL.—The Caldwell Electric Light & Power Company has filed articles of incorporation, stating its capital stock to be $15,000.

WICKLIFFE.—Mr. R. E. Gannon, of Cairo, is said to have secured the contract for an electric light plant for this city at $6042.

STURGIS.—It is stated that the town council is prepared to grant a franchise to parties who will construct and operate an electric light plant here. The town has a population of 1400.

SOMERSET.—A 250-h.p. Corliss engine and a 150-h.p. boiler have been added to the equipment of the city lighting plant. Mr. J. D. Holderman is in charge of the plant as superintendent.

FULTON.—The following officers of the Fulton Electric Light & Power Company have been elected: President and manager, Mr. L. W. Graham, and secretary and treasurer, Mr. A. L. Martin.

WILLIAMSBURG.—The Williamsburg Electric Light Company is now owned by the Nelson Brothers and Mr. P. Weesner. Mr. E. E. Nelson is manager of the company and Mr. Marshall Walls chief engineer.

HAWESVILLE.—The following are the present officers of the Hawesville Electric Light & Power Company: President and treasurer, Mr. I. C. Adair; secretary and manager, Mr. George C. Wilson, and chief engineer, Mr. George Wheeler.

LEXINGTON.—The Lexington Street Railway & Electric Light Company recently let a contract for a 600-h.p. gas engine to be installed in its power plant. Other improvements are being made at the plant, which will increase its capacity and make the equipment thoroughly modern.

HOPKINSVILLE.—The electric plant of the Hopkinsville Gas & Lighting Company was recently destroyed by fire, involving a loss which is estimated at $30,000, with $5000 insurance. The city will be seriously inconvenienced until the plant can be rebuilt, the streets and most of the business houses being in darkness in the meantime. It is understood, however, that plans are under way for a new building and that the contract has been let.

COVINGTON.—As soon as Mayor Beach and City Solicitor F. J. Hanlon issue the full text of the U. S. Supreme Court decision in the case wherein the right of Covington to build and operate an electric plant for lighting the city was established, the question of issuing $75,000 in bonds will be taken up. An expert will probably be engaged at an early date to prepare plans and estimates for a plant sufficiently large to supply electricity for the city and its citizens, and also to ascertain if the authorized bond issue of $75,000 would provide the necessary funds for that purpose.

LOUISIANA.

COVINGTON.—The St. Tammany Ice & Manufacturing Company, Ltd., has begun work on the enlargement of its electric plant here. This increase in capacity is necessitated by the large demand for light and power. Orders for the additional equipment have been placed and part of it has already been received.

VIDALIA.—The new municipal electric light plant, for which $15,000 in bonds was voted last year, has been turned over to the city complete. The cost of the plant was $10,000. The equipment consists of a 75-h.p. engine and an 85-h.p. boiler, and current is generated for 50 arc lights and 400 incandescent lamps.

OCEAN SPRINGS.—The work of installing an electric light system here has begun and will be pushed as rapidly as possible. There are to be 23 arc lights at the street crossings. The company, it is said, has agreed to furnish lights for the churches and the town hall gratis if the necessary wiring is done by the parties interested.

MAINE.

SOUTH BERWICK.—Mr. Charles W. Morse, of Hamilton, has been made president of the South Berwick & Salmon Falls Electric Company.

OLDTOWN.—It is thought probable that the big electric power house, for which partial preparation has been made, will be completed this season.

MARYLAND.

HAGERSTOWN.—Mr. J. O. Beard is now manager and superintendent of the municipal electric lighting plant.

MT. WASHINGTON.—The following have been elected officers of the Mt. Washington Light & Power Company: Mr. T. W. Offut, president and general manager; Mr. J. W. Jenkins, Jr., vice-president; Mr. H. J. McIntyre, secretary and treasurer.

CUMBERLAND.—The following-named gentlemen have been elected officers of the Piedmont Electric Light & Power Company: Mr. H. B. Carroll, president; Mr. Timothy Kenny, vice-president; Mr. Norris Bruce, secretary; Mr. W. W. Shultice, treasurer.

BALTIMORE.—Nelson Perin, who was the promoter of the present system of electric lighting in this city, died recently after a long illness, aged 51 years. Mr. Perin was one of the pioneers of rapid transit in Baltimore and was the first president of the United Railways & Electric Company which combined all the street railways of the city.

BALTIMORE.—The Maryland Telephone & Telegraph Company has begun to make use of its privilege of the city subways for supplying electric light and power. A force of men is at work drawing the cables through the conduits, and the current will be supplied for the present from the Purnell plant, which has been purchased by the company. Preparations are being made for the construction of a new central station at a cost of about $1,500,000, for which purpose the company is said to have obtained options on water-front property.

MASSACHUSETTS.

GLOUCESTER.—The Gloucester Electric Company expects soon to increase its plant equipment by the addition of a new 500-kw. steam turbine.

WOBURN.—Mr. C. L. Edgar, of Boston, is now president of the Woburn Light, Heat & Power Company, and Mr. C. J. Anderson is chief engineer.

MATTAPAN.—The Mattapan Gas & Electric Light Company of Boston was recently incorporated with a capital stock of $10,000. Mr. John H. Doherty is president of the new company.

TURNERS FALLS.—At a recent annual meeting of the Turners Falls Company it was voted to increase the capital from $300,000 to $600,000. It was also decided to continue the work of improving the power and building an electric plant. Mr. C. T. Crocker is president.

SPRINGFIELD.—At a recent meeting of the Board of Aldermen, it was recommended that another generator be installed in the electric light plant, and that proper provision be made for reserve capacity; that $3000 be furnished for new electric meters and as large a sum be appropriated for transformers.

MICHIGAN.

LAPEER.—Mr. F. J. Schlegel is now president of the Lapeer Light & Power Company.

BLISSFIELD.—Mr. R. H. Ellis is now superintendent of the municipal lighting plant.

CASS CITY.—Mr. W. N. Straube is now superintendent of the municipal electric light and water palnt.

NEGAUNEE.—Work has begun on the construction of the new gas and electric light plant for this place.

SAULT STE. MARIE.—The Edison Company is making preparations for the construction of an electric light station.

MILFORD.—Mr. F. S. Hubbell, owner of the electric light plant here, is arranging for improvements to his steam equipment.

MANTON.—Bids have been requested for repairing the electric light plant and water works. The cost is estimated at $5000.

OXFORD.—The village of Oxford is replacing the transformer now in use at its electric light plant with a machine of larger capacity.

BELDING.—Mr. J. E. Stanton is now occupying the position of chief electrician for the Spencer Electric Light & Power Company.

ITHACA.—It is said that the lighting plant and power plant formerly owned by the Ithaca Light & Power Company is now being operated by the village.

BRONSON.—William H. Friedrich & Co., owners of the electric light plant here, expect to build another mile of line and will install a new generator in their plant by fall.

CARO.—The Caro Light & Power Company, successor to the Caro Electric Light Works, has a paid in capital of $25,000. Mr. L. R. Peck is manager and superintendent.

MARSHALL.—Mr. P. S. Joy, superintendent of the Marshall lighting plant, writes that in all probability the old Brush arc dynamos will be replaced this summer by series alternating-current machines.

BATTLE CREEK.—Mr. Charles C. Green continues as president of the Citizens' Electric Company; Mr. F. A. Allwardt has been elected secretary and treasurer, and Mr. D. H. Beardsley is manager.

RAPID CITY.—Engineers are looking over the water-power sites on Rapid River with a view to constructing a plant to furnish electricity for lighting Rapid City, Alden and the resorts on Torch Lake.

CHELSEA.—Mr. B. Parker is secretary of the municipal electric light and water works; Mr. W.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

F. Riemenschneider is treasurer; Mr. C. W. Lightball, manager and superintendent, and Mr. W. H. Heselschwerdt, purchasing agent.

DETROIT.—The present officers of the electric light plant are as follows: President, Mr. E. H. McCurdy; vice-president, Mr. B. Grusburg; secretary, Mr. F. T. Bowler; manager and superintendent, Mr. William M. Daly, and chief engineer, Mr. W. F. Cullen.

KALAMAZOO.—The installation of 21 direct-current, enclosed-arc lights is being considered by the Council, and a new engine and boiler will probably be added to the equipment of the municipal electric light plant. Mr. E. W. Messany is superintendent of the plant.

SCHOOLCRAFT.—The power house of the village municipal electric lighting plant was destroyed by fire the morning of May 15. The plant had been in operation only since last December and the loss on machinery and buildings is estimated at $7000, about $5000 of which is covered by insurance. Steps will be taken to rebuild at once, but at the best the village will be in darkness for sixty days.

MUSKEGON.—Mr. George Erwin is said to be interested in the construction of three dams on Muskegon River, one at Rogers Bridge, another at the Davis Bridge, and the third still further down. It is estimated that about 10,000 horse-power can be produced. An electrical power house will be built at each dam and the current obtained will be transmitted to Grand Rapids, Big Rapids and Muskegon.

PENTWATER.—A contract has been closed between the village and the Oceana Electric Company, by which the company will operate the local water plant and will also install equipment to furnish twenty arc lights for the village and current for all private consumers at 50 cents per 32-c.p. incandescent lamp. The arc lights are to be of 1000 candle-power and to cost $75 per month for the twenty lamps. The plant is to be installed before December 31.

CONSTANTINE.—The Constantine Hydraulic Company has the city lighting contract for this city and Three Rivers. Each city has a sub-station in each of which are three 75-kw. step-up transformers by means of which the current is raised from 1100 to 2300 volts, and three step-down transformers for the reverse operation. Mr. George Flyten, Chicago, is president; Mr. L. J. Bolting, Three Rivers, secretary, treasurer and manager, and Mr. G. L. Shoup, this city, superintendent.

KALAMAZOO.—The Kalamazoo River recently formed a new channel around the southern end of the big dam at the Otsego power plant of the Kalamazoo Valley Electric Company, depriving the plant of its supply of water. As most of the cities between Kalamazoo and Jackson, as well as the Jackson-Battle Creek Interurban road, depend upon this plant for power, business was temporarily suspended while the Otsego dam was being disconnected from the others. It required about ten days to repair the damage.

DETROIT.—The Michigan Association of Electric Light Managers was recently organized in this city by managers of different lighting plants throughout the state. Mr. E. F. Phillips, assistant manager of the Edison Illuminating Company, of Detroit, was elected president, and Mr. F. S. Hubbell, of Milford, was chosen secretary. Several committees were appointed to take charge of the work of perfecting plans for future endeavor. Those present were E. F. Phillips, Detroit; J. B. Foote, Jackson; R. W. Hemphill, Ann Arbor; S. E. Padfield, St. Clair; A. R. McKennon, Cheboygan; F. L. Prindle, Gladwin; A. L. Pond, Coldwater; J. H. Kingsley, Manchester; G. A. Krause, Rockford; F. R. Gallop, Pontiac; F. S. Hubbell, Milford.

MINNESOTA.

ELY.—Mr. T. W. Tool is at present chief engineer of the city electric light plant.

GRAND RAPIDS.—Mr. O. P. Finis is now superintendent of the municipal electric light plant.

EXCELSIOR.—Dr. F. B. Kramer has petitioned for a franchise for an electric light plant and water works.

FULDA.—The Fulda Light & Water Plant (municipal) is now in charge of Mr. W. H. Blair as superintendent.

SOUTH STILLWATER.—The council has advertised for bids for the construction of an electric light plant.

LAKE CITY.—The municipal lighting plant will install a new engine and dynamo shortly, changing from direct to alternating current.

MONTEVIDEO.—The Montevideo Electric Light & Power Company is pushing rapidly its work of developing Minnesota Falls.

MADISON.—The city lighting plant is being improved by the installation of a new boiler and heater; a new system of piping is also being put in.

NEW PRAGUE.—A new engine and boiler are to be installed in the power house of the lighting plant here, bids for which were recently called for.

JANESVILLE.—Village Recorder L. D. Rogers writes that bids have been called for to construct an electric light plant and water works at a cost of $25,000.

FERGUS FALLS.—The Electric Light Commission has recommended the setting aside of $8000 toward rebuilding the dam which was destroyed a short time ago.

CHATFIELD.—Rev. S. Maddock has been made secretary of the Chatfield Electric Light & Power Company, to fill the vacancy made by the recent death of Mr. F. T. Drebert.

ROCHESTER.—The organization of a company to establish an electric plant to be operated from the water power at Jarrett is being discussed. The water power is owned by Mr. F. G. Colburn.

BELGRADE.—Mr. C. M. Iverslin is president of the village electric light and water plant; Mr. John Chisholm, secretary; Mr. A. J. Linquist, treasurer; Mr. P. B. Benther, manager and chief engineer.

THIEF RIVER FALLS.—The following are the present officers of the city electric light plant: President, Mr. M. C. Harlow; vice-president, Mr. Hans Langseth; secretary, City Clerk L. Backe, and superintendent, Mr. Leonard Peterson.

WHITE BEAR.—Amended articles of incorporation have been filed by the White Bear Electric Company, in which the capital stock was increased from $10,000 to $25,000. Mr. George H. Rief is president and Mr. F. E. Whitaker is secretary of the corporation.

LUVERNE.—The officers of the village electric light plant are as follows: President, Mr. E. A. Brown; secretary, Recorder E. C. Schwartz; treasurer, Mr. A. Ross; purchasing agents, Messrs. E. A. Brown, E. C. Shultz and George Leet; chief engineer, Mr. L. J. Chilbuck.

ST. PAUL.—The officers of the St. Paul Gas Light Company, which is now controlled by the Edison Electric Light & Power Company, are as follows: President, Mr. Emerson McMillan, of New York; vice-president and manager, Mr. Paul Doty; secretary and treasurer, Mr. John P. Crowley; and superintendent, Mr. H. J. Gilles.

DULUTH.—The Great Northern Power Company, of this city, has under way some very extensive improvements, by means of which it is proposed to have a 35,000-h.p. plant in operation in 1905, while the plans provide for an additional increase in capacity up to 80,000 horse-power. The company is now installing vertical turbines and other apparatus to operate at 250 revolutions per minute under a 365-ft. head, and another hydraulic installation of 12,000 horse-power at a 70-ft. dam is also contemplated.

CHISHOLM.—The Chisholm Light & Power Company, which recently filed articles of incorporation, expects to have its plant in operation shortly. Duluth will be the principal place of business of the company, which is capitalized at $20,000, and composed of Mr. Nils Anderson, of Virginia, Mr. Henry A. Liedel and Mr. Daniel D. Crowley, of this city. In addition to furnishing lighting and power current for the village, the facilities of the plant will also be utilized by the mines, which have heretofore used candles, and for the tripping work that is being done in the vicinity of Chisholm.

CLOQUET.—The Cloquet Electric Company has just closed a contract with the General Electric Company for a two-phase, 60-cycle, 2300-volt, alternating-current generator with direct-connected exciter to operate at 150 r.p.m., and with the Ball & Wood Company for a 14-in. and 28 in. x 27-in. Corliss valve compound condensing engine. The engine is to develop a horse-power-hour on 14 pounds of dry steam and 26 inches of vacuum. The engine builders are to forfeit $1000 for each pound or proportionate fraction thereof in excess of 14, pounds and are to receive a bonus of $1000 for each pound or proportionate fraction thereof saved in the economy thereof. The test will be made in September and will undoubtedly be watched closely by electrical and engine men.

MISSISSIPPI.

OXFORD.—The citizens have voted for improvements to the electric light plant.

BENOIT.—Mr. C. L. Lourey, an oil promoter, is said to be securing stock for a $100,000 oil mill, an electric light plant and water works.

BAY ST. LOUIS.—Mr. A. L. Stoker, proprietor of the electric lighting plant here, contemplates installing a new direct-connected engine and generator soon.

HATTIESBURG.—The City Clerk writes that the matter of constructing an electric light plant, for which $60,000 in bonds was to have been issued, has been postponed indefinitely.

CLARKSDALE.—Rather extensive improvements are under way at the municipal electric lighting plant, which will include a 400-kw. dynamo with the necessary steam equipment, together with a complete new switchboard.

WINONA.—The following are the officers of the Winona Water, Sewerage, Ice & Light Company: President, Mr. C. R. Kelso; secretary and manager, Mr. H. R. Romberger; treasurer, Mr. H. M. Romberger; chief engineer, Mr. William Dunnegan.

KOSCIUSCO.—The officers of the Kosciusco Oil Mill & Fertilizer Company, which owns and operates the lighting and power plant of this city, are as follows: President, Mr. W. B. Potts; vice-president, Mr. A. L. Dodd; secretary and manager, Mr. C. V. Jones; superintendent, Mr. Henry Miller, and chief engineer, Mr. L. Thomton.

BATESVILLE.—The Batesville Electric Light Plant, formerly owned by Mr. D. L. Rush, is now owned and operated by the Panola Electric Light & Power Company. The company expects to build a line to Sardis, nine miles distant, for the purpose of lighting Batesville by current transmitted from the Sardis plant. The Panola Electric Light & Power Company is capitalized at $25,000, and is officered as follows: Mr. A. W. Shands, Sardis, president; Mr. D. L. Rush, Sardis, secretary and superintendent; Mr. Monroe Pointer, Como, treasurer.

MISSOURI.

CARTHAGE.—Mr. A. P. Knowles has been made superintendent of the city electric light plant.

BETHANY.—Mr. J. F. Shuger is now manager of the municipal plant of the Bethany Light & Water Works.

SALISBURY.—A 100-kw. alternator and a 200-h.p. boiler are soon to be installed in the municipal electric light plant.

GALLATIN.—Mr. P. Love is now superintendent of the municipal electric light plant, Mr. J. J. A. Carter being chief engineer.

LOUISIANA.—The Louisiana Gas & Electric Light Company will probably make some improvements in its plant in the near future.

HANNIBAL.—Several contracts have been closed by the Board of Public Works for machinery, etc., for the new $100,000 municipal electric light plant.

BOLIVAR.—Mr. W. G. Smith has succeeded Mr. James Cruickshank as superintendent and chief engineer of the Bolivar Electric Light & Water Works Company.

VERSAILLES.—Bids were recently called for to furnish all labor, material and equipment necessary for the installation of a complete electric lighting plant in this city.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

WARRENTON.—The Warrenton Electric Company has been succeeded by the Electric Company of Warrenton, of which Mr. J. H. Frick is president; Mr. F. E. Schowengerdt, secretary, and Mr. Charles Schroeder, treasurer.

JOPLIN.—It was stated recently that an election was to be held to vote for the issue of $30,000 in bonds to improve the municipal lighting plant. It is proposed to install a new generator, engine and boilers. Mr. J. R. McDonald is superintendent.

LAMAR.—The plant of the Lamar Light & Water Company is being operated to the limit of its capacity and there is a large demand for more lights. The company will either replace the present machinery with larger units or install a duplicate of the set now in use.

WEBSTER GROVE.—The Suburban Electric Light & Power Company now controlls the Electrical & Maintenance Company and the St. Louis County Electric Company. Current for lighting purposes is also furnished to Maplewood, Kirkwood and Greenwood. The following are the company's officers: President, Mr. C. C. Einstein; vice-president, Mr. Paul W. Coble; secretary and treasurer, Mr. H. C. Holmes; manager and superintendent, Mr. S. H. Wallace, and chief engineer, Mr. A. F. Covert.

SEDALIA.—The United Water, Gas & Electric Company, which is a consolidation of the Sedalia Water & Light Company, the Gas Company and the Street Railway Company's lighting plant, has filed articles of incorporation with a capital of $1,000,000. Messrs. Lewis M. Rumsey, Jr., Horace S. Rumsey and Joseph Clarke are among the incorporators. The company will construct, acquire, maintain and operate water works, gas works, electric lighting and power plants, street railways and steam power plants in and adjacent to the city of Sedalia.

NEBRASKA.

LINCOLN.—Electric light bonds to the amount of $65,000 have been sold.

FREMONT.—The council is considering making additions to the electric light plant.

ALBION.—Mr. C. M. Sinnard is chief engineer of the Albion Electric Light & Power Plant, which is owned by Mr. H. Rice.

TEKAMAH.—The electric light plant at this city was seriously damaged by a tornado on June 2, leaving the town in complete darkness.

CAMBRIDGE.—The Cambridge electric light plant, which has been operated under the management of Mr. P. B. Cole, has been organized as the Cambridge Electric Light Company with a capital of $10,000. Aside from the lighting plant, the articles of incorporation include the maintenance of a heating plant and a system of water works which will be put into effect later. The directors are Messrs. W. H. Faling, J. H. Rosenfelt, E. C. Rodwell and others.

NEVADA.

RENO.—This city is to have two water and power companies. Work on the opposition plant is to begin at once. Governor Sparks is the principal owner of the new enterprise and announces that the company will be prepared to furnish water and light not later than next spring. The company owns water rights on Hunter Creek, five miles north of the city.

VIRGINIA.—The Truckee River General Electric Company is making arrangements to install an additional plant of from 2000 to 3000 horse-power capacity, to be operated by water power. Surveys are also under way for a new 35-mile transmission line, and a new sub-station will be erected this summer. The headquarters of the company, formerly at San Francisco, is now in this city, where it has bought out the T. H. Electric Light Company and the Carson Light & Power Company. Mr. F. O. Broili is superintendent.

NEW HAMPSHIRE.

MILFORD.—Considerable progress is being made in the construction of the electric light service from here to Amherst.

MARLBORO.—The following-named gentlemen have been elected officers of the Marlboro Electric Light Company: Mr. O. A. Norwell, of Boston, president; Mr. Lewis H. Tiffin, Providence, treasurer; Mr. Edwin C. Mansfield, Meredith, manager.

PORTSMOUTH.—The board of tax assessors recently voted to assess the entire light and power plant of the Rockingham County Electric Light & Power Company of this city. When this plant, which is the largest in the state, was built the city voted to exempt all new work of the company from taxation for a period of ten years, and since then a plant has been developed which is estimated to have cost $500,000. The action of the assessors is based on a decision of the Supreme court that all votes of cities and towns exempting from taxation light and power plants are illegal and void. The company furnishes power for the New Hampshire Traction Company's electric road, with lines running as far as Nashua, Lowell and Haverhill.

NEW JERSEY.

VINELAND.—Mr. R. H. Garrison is now superintendent of the electric lighting plant of the borough of Vineland.

CAMDEN.—The Public Service Corporation Company has just been awarded a five-year contract by the Lighting Committee to supply 524 arc lights at $109 per year per lamp.

HADDONFIELD.—There is some discussion among the taxpayers of the town concerning the question of constructing and maintaining a municipal electric light plant and water works.

JERSEY CITY.—The Commonwealth Electric Company has been incorporated with a capital of $100,000 for the purpose of furnishing light, heat and power. The company's office is at 15 Exchange Place, Jersey City.

NEWARK.—Mr. D. Farrand, secretary and manager of the People's Light & Power Company which is controlled by the Public Service Corporation of New Jersey, has been elected secretary of the National Electric Light Association.

SUSSEX.—The Woodbourne Electric Light, Heat & Power Company recently elected the following officers: President, Mr. Charles A. Wilson; vice-president, Mr. C. H. Chrisman; secretary, Mr. A. W. Deldell; treasurer, Dr. H. D. Van Gassbeck.

BEVERLY.—The Cinnaminson Electric Light Company is now known as the Cinnaminson Electric Light, Power & Heat Company. The company also furnishes lighting current to Edgewater Park, Delanco, Riverside, Palmyra, Riverton and West Freehold. Mr. Charles Major is chief engineer.

NEWTON.—The contract has been let for the installation of a 300-h.p. plant for lighting the town. The equipment consists of two American Crossley two-cylinder horizontal gas engines of 200 and 100 horse-power respectively, direct-connected to 150-kw. and 75-kw. alternating-current generators.

NEW MEXICO.

CARLSBAD.—The Carlsbad Electric Light Plant, formerly known as the Eddy Electric Light Plant, is now owned by Mr. C. H. Klander.

ROSWELL.—The Roswell Electric Light & Power Company, which began operations recently, is preparing to extend its lines, material for which has been ordered. Mr. Maynard Gunsul, of Albuquerque, is president; Mr. C. M. Bird, secretary, and Mr. W. H. Pierce, manager and superintendent. It is understood that the company also controls the Gallup Electric Light Company, of Gallup, this state.

NEW YORK.

CAZENOVIA.—The Cazenovia Electric Company is installing underground circuits.

WARSAW.—Mr. W. E. Hemenway is now superintendent of the Warsaw Gas & Electric Company.

CLINTON.—Arrangements are being made for the construction of a municipal electric light plant.

GREEN ISLAND.—Mr. Daniel Catarius has been appointed superintendent of the village lighting plant.

LITTLE VALLEY.—Mr. C. P. Rice has been appointed superintendent of the village electric light plant.

NIAGARA FALLS.—The Niagara Falls Hydraulic Power & Manufacturing Company is contemplating the erection of a new power house.

PENN YAN.—Bids were recently advertised for to furnish boiler, engines, alternators, arc lamps, etc., for use in the municipal electric lighting plant.

SALEM.—The following are the officers of the Salem Electric Light & Power Company; Mr. George Austin, president; Mr. E. W. Philo, secretary and manager.

ALBANY.—The Albany Electric Illuminating Company is preparing to change from steam to water power. Mr. A. N. Brady is president and Mr. A. Anderson, manager and superintendent.

HUNTINGTON.—The Huntington Light & Power Company has recently installed new engines and dynamos for the purpose of furnishing power for the operation of the new Huntington trolley line.

KINGSTON.—Surveyors have begun the work of locating the line for the poles and wires to bring electrical power from the Honk Falls power plant to this city for the use of the Honk Falls Power Company.

BAY SHORE.—Mr. W. A. Wright, of New Haven, Conn., is president of the Suffolk Gas & Electric Company; Mr. W. S. Pardee, New Haven, is secretary and treasurer, and Mr. A. M. Hallock is superintendent.

NEWARK.—Mr. H. M. Whitehead, superintendent of the City Water Company of this city, has resigned his position with that company and assumed the management of the light and power plant at Port Jervis, N. Y.

GOWANDA.—Mr. W. R. Smallwood has assumed the management of the Gowanda Consolidated Electric Light & Fuel Company. It is understood that extensive improvements and alterations will be undertaken in the near future.

LOCKPORT.—A contract has just been closed with the Lockport Gas & Electric Light Company for lighting the city for a period of three years at $75 each for arc lights and $17.50 each for gas lamps; there are 300 of the former lights in use.

TROY.—The Troy Gas Company, which now controls the Beacon Electric Light Company, is installing in its station two 40-cycle synchronous motors, also a motor-generator set, the machines to be operated by power obtained from Spiers Falls.

GRANVILLE.—The Granville Gas & Electric Light Company has begun work on the construction of its dam at Lake St. Catherine. The company expects shortly to erect a line to Whitehall and will ask for a franchise to operate in that village.

NEW YORK CITY.—The Ramona Natural Gas Light, Heat & Power Company of New York City has been incorporated, with a capital stock of $100,000 and the following directors: Messrs. Howard McWilliams, A. L. Cohn and C. S. Steckmest, this city.

CLYDE.—Mr. George Brooks has been made superintendent of the Wayne County Electric Lighting Company's plant in this village, to succeed Mr. George Rodwell, who resigned his position here to accept one with the Syracuse Lighting Company.

MIDDLETOWN.—The Consumers' Light & Power Company has elected the following officers: President, Mr. J. G. Harding; vice-president, Mr. William Snyder; secretary, Mr. Isador Budwig; treasurer and manager, Mr. D. C. McMonagle; superintendent, Mr. C. S. Warner.

LOCKPORT.—Press reports state that the Niagara, Lockport & Ontario Power Company will build the canal under the present charter and seek an amendment next year, which will authorize it to sell power to all counties of the state instead of only Erie, Niagara and Orleans.

TANNERSVILLE.—Messrs. Jacob Fromer, Geo. Hanner and Cyrus Showers, all of Tannersville, recently organized the Tannersville Electric Light & Power Company with a capital stock of $20,000. The company will furnish electricity to the town of Hunter, Greene County.

JAMESTOWN.—Charles W. Grant died suddenly at his home in this city on May 10. Mr. Grant was one of the organizers and for many years the

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

president of the Jamestown Electric Light & Power Company. He was 60 years old at the time of his death and leaves a widow and one daughter.

BATH.—Mr. Cameron Cotton, who for several years has been chief engineer at the plant of the Bath Electric Illuminating & Power Company, has resigned his position with that company. It is rumored that Mr. Cotton will be identified with the new electric light company which is soon to commence operations in the village.

SANDY HILL.—The preparations of the United Gas, Electric Light & Fuel Company for obtaining power from the Union Bag & Paper Company, of Bakers Falls, are nearly complete and it is probable that the villages of Sandy Hill and Fort Edward will be supplied with current for lighting and power purposes from the Bakers Fall plant.

MASSENA.—The St. Lawrence County Electric & Water Company is a consolidation of the St. Lawrence Telephone Company, the St. Lawrence Water Company and the Massena Electric Light & Power Company. The president is Mr. T. A. Gillespie; secretary and treasurer, Mr. E. B. Bumsted, both of New York City, and manager, Mr. A. E. Russell, of this city.

LE ROY.—The Le Roy Hydraulic Electric Company, the Le Roy Gas & Electric Company and the Le Roy Power & Milling Company, all of this village, have combined under the name of the Le Roy Hydraulic Electric Gas Company, the capital stock being fixed at $100,000. A number of improvements in the plants are to be made and the business considerably extended.

BROOKLYN.—The Kings County Lighting Company has been incorporated, with a capital stock of $2,000,000. The company will operate in Brooklyn and Queens boroughs, manufacturing and selling gas and electricity. Messrs. Ashley T. Cole and Charles T. Lark, New York City; William J. Bagnall, Bayonne, N. J.; Alexander Keogle, New Rochelle, and W. R. Fuller, Brooklyn, are named as the directors.

ADDISON.—The entire plant of the Addison Electric Light & Power Company was destroyed by fire recently. The pumping station near the electric light plant and the planing and saw mill of McElroy & Wheadon, who owned all of the property, were also burned. The loss is estimated at $50,000 and is total, there being no insurance. The plant will probably be rebuilt immediately.

ALBION.—The Albion Electric Light, Power & Gas Company, which also owns the electrical plants at Waterport, Brockport and Middleport, is said to be interested in a deal for the development of a large water power at the latter village, approximating 25,000 horse-power. It is proposed to purchase the paper mill site just north of the village and combine the power of that site with the water power sites on the creek below. The whole of the power thus obtained will be utilized for the generation of electricity.

NORTH CAROLINA.

MT. OLIVE.—Plans and estimates are being prepared for an electric light plant.

REIDSVILLE.—Mr. T. S. Murphy is chief engineer of the Reidsville Water & Light Plant.

GREENVILLE.—Bids for the construction of an electric light plant were recently advertised for.

LEXINGTON.—It has been voted to issue $60,000 bonds for the construction of water works, an electric light plant and for new pavements.

FAYETTEVILLE.—The city now owns its own electric light plant, and reports state that the demand for current has so increased of late as to make necessary improvements which will nearly double the capacity of the plant.

SHELBY.—Messrs A. W. McMurry and Hugh G. Miller, proprietors of the electric light plant of this place, contemplate rebuilding the plant and will probably change over from the present single-phase system to a three-phase system.

RALEIGH.—The following are the officers of the Standard Gas & Electric Company: Mr. S. E. Linton, president and manager; Mr. J. S. Carr, vice-president; Mr. H. W. Jackson, secretary and treasurer; Mr. C. F. Farmer, superintendent.

WILSON.—A charter has been granted to the Wilson Light & Power Company, recently incorporated with a capital stock of $125,000 by Messrs. J. C. Hale, B. F. Lane, Claudius Aycock, E. L. Armfield and David Daniels, for the purpose of maintaining a lighting and power plant.

GREENSBORO.—The Greensboro Electric Company operates the gas and electric plants and furnishes power for the street railway and city pumping. Mr. John Karr, of Hackettstown, N. J., is president of the company; Mr. Z. V. Taylor, secretary; Mr. M. D. Barr, treasurer; Mr. R. H. Gamwell, manager; Mr. A. H. Jones, superintendnet, and Mr. R. E. Pentecost, chief engineer.

SOUTHERN PINES.—It was erroneously stated in these columns last month that the electric plant of this town was owned by Mr. R. L. Chandler and known as the R. L. Chandler Electric Light Plant. This plant has only its office in this city and lights the towns of Troy and Biscoe. The Southern Pines plant is owned by Mr. I. F. Chandler and furnishes lighting current to the towns of Carthage and Aberdeen, besides Southern Pines.

ELIZABETH CITY.—The Elizabeth City Electric Light & Power Company was recently organized by the consolidation of the Electric Light Company of Elizabeth City, Elizabeth City Electric Light & Power Company and the Elizabeth City Water & Power Company. Mr. D. E. Evans, of Baltimore, Md., is president; Mr. W. T. Old, vice-president; Mr. H. Clay Tunis, secretary, treasurer and manager, and Mr. R. E. Lewis, superintendent. The company furnishes current for 316 city incandescent lights, 70 commercial arc lamps and 3100 commercial incandescent lights.

NORTH DAKOTA.

LIDGERWOOD.—The council is considering the construction of an electric light plant, and it is thought that the matter will be acted upon favorably.

WIMBLEDON.—The electric light plant has been purchased by Mr. Fred Zollner, of Courtenay, N. D., who will install additional machinery and otherwise improve the plant.

FARGO.—Mr. Harry Hoffman, who resigned his position as superintendent of the municiapl electric light plant last summer to accept a similar one near Spokane, has returned to this city and is again occupying his former position.

FARGO.—The Fargo Gas & Electric Company has been consolidated with the Fargo Edison Company under the name of the Union Light, Heat & Power Company. The officers of the new company are as follows: President, Mr. William Mainland, Oshkosh, Wis.; vice-president, Mr. J. W. Smith, Fargo; secretary, Mr. O. G. Barnes, Fargo; treasurer, Mr. Sinclair Mainland, Green Bay, Wis.; manager, Mr. O. G. F. Markhus, this city. The company is making improvements and addition to the plant, increasing the equipment and thereby the capacity.

OHIO.

HURON.—Mr. B. O. Brooks is chief engineer of the Huron electric light plant.

NORTH AMHERST.—Mr. H. W. Strauss is now chief engineer of the municipal lighting plant.

BAINBRIDGE.—A new dynamo is being installed in the Bainbridge electric light plant.

CELINA.—Mr. J. N. Houser has been made superintendent and chief electrician of the city lighting plant.

DELPHOS.—Mr. Pierce Kinsley is now superintendent of the Delphos Electric Light & Power Company.

WEST MILTON.—The Council has under advisement the question of establishing an electric light plant.

WELLSTON.—Mr. Thomas Morgan is now in charge of the city lighting plant as manager and chief engineer.

COLUMBIANA.—Mr. H. C. Fashbaugh is superintendent and chief electrician of the village lighting plant.

WILLIAMSBURG.—Report state that bids have been received for constructing an electric light plant and town hall.

TIFFIN.—Mr. Thomas Esty has been made superintendent of the plant of the Consolidated Gas & Light Company.

ORRVILLE.—The Orrville Light, Heat & Power Company is preparing to install an incandescent system of street lighting.

BEVERLY.—The plant of the Beverly Electric Light Company, formerly owned by Mr. I. A. Frost, is now operated by the city.

DOYLESTOWN.—The proposition to issue $10,000 of municipal lighting bonds is soon to be submitted to a vote of the citizens.

HILLSBORO.—The contract for lighting the city for a term of ten years has been awarded to the Hillsboro Light & Fuel Company.

MIAMISBURG.—Mr. Mott Ware has been elected president of the electric light plant and Mr. J. G. Jacobs is secretary and manager.

BELLEFONTAINE.—The town authorities expect to rebuild the entire electric light plant next year. Mr. C. W. Buchanan is manager and superintendent.

GLOUSTER.—Glouster is to have an electric light plant, the contract for the construction of which has been let to the Russell Engine Company for $16,422.

WEST MANSFIELD.—Contracts for the construction of an electric light plant will soon be let, bonds to the amount of $11,000 having been sold for the purpose.

GENEVA.—Mr. Charles H. Hawes has been made superintendent of the Geneva Electric Illumoinating Company, formerly known as the Geneva Lighting Company.

CONNEAUT.—Mr. J. K. Henderson is superintendent of the municipal electric light plant; Mr. John Lovell is chief engineer, and Mr. E. M. Marsh is his assistant.

SALEM.—The Salem Light & Power Company has been incorporated with a capital of $10,000 by Messrs. J. S. Klinefelter, J. G. Wilson, C. M. Wilson, E. N. Grove and others.

OBERLIN.—The Oberlin Gas & Electric Company recently completed the installation of a very complete steam heating system and plant, which is operated in connection with its electric plant. A. E. Hay is manager and superintendent.

ZANESVILLE.—The city authorities are considering the advisability of installing electrical apparatus in their present water works pumping station and generating their own lighting current. The city pays at present $20,000 per year for lights.

PRAIRIE DEPOT.—A franchise has been granted to Messrs. Harry L. and Charles H. Wilson, of Fostoria, for operating the electric light plant which has been idle for several months. The plant has been thoroughly repaired and is now in operation.

BRIDGEPORT.—The Bridgeport Electric Light & Power Company has elected the following officers: Mr. A. L. Snowden, of Philadelphia, Pa., president; Mr. H. T. Hartman, Philadelphia, vice-president, and Mr. John B. Gardner, Wheeling, W. Va., secretary and manager.

RIPLEY.—The electric light plant is now operated in connection with the gas plant under the name of the Ripley Gas Light & Coke Company. Mr. F. A. Stivers is president of the company; Mr. C. Baird, vice-president, and Mr. J. C. Leggett, secretary, treasurer and manager.

BEDFORD.—The People's Electric Light Company has increased its capital stock to $50,000. Mr. Edward Roberts, of Philadelphia, is now president of the company, and Mr. E. E. Mandeville, also of Philadelphia, secretary; Mr. W. S. Pettibone, Cleveland, treasurer; Mr. Stanley Smith, superintendent.

NEW PHILADELPHIA.—The A. Beyer & Leiser Electric Company is now furnishing lighting current to the town of Canal Dover. The officers of the company are as follows: Mr. A. Beyer, president and manager; Mr. W. H. Leiser, secretary; Mr. F. A. Duck, treasurer; Mr. Harry Slasor, superintendent and chief electrician; Mr. A. A. Leiser, chief engineer.

EATON.—The consolidation of the Eaton Light & Artificial Heat Company and the Electric Light,

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

Power & Ice Manufacturing Company, which was announced in these columns last month, will be known as the Eaton Public Service Company, which has been incorporated with a capital stock of $200,000. Messrs. C. S. Glass, H. J. Phillips and J. R. Cook are among the incorporators.

CINCINNATI.—Brig.-Gen. Andrew Hinckenlooper, for the past thirty years president of the Cincinnati Gas & Electric Company, died recently at the age of sixty-seven. He rose from captain to brigadier-general in the civil war, and was a famous commander of artillery in the Union army. After the war he was civil engineer of Cincinnati, and from 1880 to 1882 was lieutenant-governor of Ohio.

RICHWOOD.—The electric light plant, formerly owned by Mr. E. A. Schambs, has been consolidated with the Richwood Light, Heat & Power Company under the name of the latter. The new company has a capital stock of $20,000 and the officers are as follows: President, Mr. O. P. Lenox; vice-president, Mr. L. G. Peet; secretary and manager, Mr. L. P. Allbright; treasurer, Mr. B. Cahill; superintendent, Mr. M. Walton.

NEWTON FALLS.—Mr. E. E. Mandeville, of Philadelphia, has been awarded the contract for lighting the village with electricity for a term of ten years, together with a twenty-year franchise for furnishing commercial lighting and power current. According to the terms of the contract, he is to build and equip the plant and furnish 16 arc lights at $70 per lamp, the service to begin within three months.

NORWALK.—The Norwalk Gas & Electric Company has been absorbed by the Cleveland & Southwestern Traction Company, the officers of which are: President, Mr. F. T. Pomery; vice-president, Mr. A. E. Akins; secretary, Mr. E. F. Schneider; treasurer, Mr. E. L. Fuller; all of Cleveland; manager, Mr. H. A. Nichall, Kamms, Ohio; superintendent, Mr. J. A. Nester, Elyria; chief engineer, Mr. E. C. Hundert, Elyria.

COLUMBUS.—Superintendent M. S. Hopkins, of the Columbus Railway & Light Company, recently submitted figures to the City Council relating to the cost of production and distribution of electric current during the year 1903, as shown by the records of the company. The figures included the price paid by the city for street lighting, and when this contract is taken away the average cost of production and distribution per kilowatt-hour will be materially increased. According to the report, the cost of distribution per kilowatt was 2.7 cents and the cost of manufacture 1.243 cents; 10 per cent. depreciation on the actual amount invested represents 2.734 cents a kilowatt, and interest at 5 per cent. was 1.57 cents. The total cost of current furnished over the pole lines only was 7.937 cents a kilowatt, while the average rate received, including street lighting, was 7.27 cents. Mr. Hopkins asked that the price schedule recently fixed by Cincinnati be adopted in Columbus. The Cincinnati ordinance fixes a maximum price of [illegible]1 cents a kilowatt, with a minimum charge of $1 per month. It also provides for a system of discounts based on 16-candlepower lamps or their equivalent, ranging from 5 per cent. on 2000 or 3000 watt-hoursto 40 per cent. on 9000 or over. He said the company is now expending $365,000 in remodeling its machinery and extending its service, and that in a short time there would be no part of the city without light.

OKLAHOMA TERRITORY.

ENID.—The following are the officers of the Enid Electric & Gas Company, which began operations last year on a capital of $200,000. Mr. H. M. Byllesby, of Chicago, president; Mr. J. S. Cummins, Chicago, vice-president; Mr. Robert Graf, Chicago, secretary and treasurer; Mr. T. K. Jackson, this city, chief engineer and electrician.

OREGON.

PORTLAND.—Mr. E. Hippeley is now chief engineer of the Portland General Electric Company.

SPRINGFIELD.—The light and power plant of the Lane County Electric Company at this place is now in operation and will continue to furnish Eugene and adjacent towns with light and power.

PORTLAND.—The Washington Water Power Company, of Portland, is arranging to increase the capacity of its plant five-fold, giving the city plants 70,000 horse-power, at an estimated cost of $1,500,000.

PENDLETON.—The Northwestern Gas & Electric Company, which recently purchased the Pendleton electric light plant, has secured a 25-year gas franchise, and construction work on the new plant will begin shortly.

PORTLAND.—The director of the works at the Lewis and Clark Fair is receiving bids for furnishing electric current for lighting and power purposes on the exposition grounds and in the various buildings.

DALLAS.—Mr. M. D. Ellis, for three years proprietor of the electric light plant, has sold his entire interest in the establishment to Mr. J. G. Van Orsdel. Mr. Van Orsdel, it is said, contemplates extensive alterations to the plant and will put in improvements to the extent of several thousand dollars. Mr. Frederick West has been retained by the new management as chief engineer.

COTTAGE GROVE.—The Cottage Grove Electric Company recently absorbed the Cottage Grove Electric Light Company and is now building extensions to its lines. The following-named gentlemen are the company's officers: Mr. W. M. Sheehy, president and superintendent; M. W. Thompson, vice-president; H. O. Thompson, secretary, treasurer and manager; T. C. Abrams, chief engineer and electrician.

LA GRANDE.—The La Grande Light & Power Company has sold its entire holding to the Thronson Stock & Land Company in consideration of $40,000. The latter company is composed of J. A. Thronson, C. J. Thronson, Thomas Thronson and C. J. Broughton, of Dayton, Wash. Mr. J. Thronson is president and Mr. C. J. Thronson, treasurer. Mr. Fred M. Housh, who for some weeks past has been acting as electrician for the old firm, has been retained by the new management as superintendent and assistant manager. About $16,000 will be expended by the new company in improvements.

PENNSYLVANIA.

GIRARD.—The city now owns its own electric light plant. Charles Eggleston is chief engineer.

TARENTUM.—Mr. J. H. Humphrey is now in charge of the borough lighting plant, as superintendent.

PECKVILLE.—Mr. T. C. Williams is now chief engineer of the municipal lighting plant operated by the Borough of Blakeley.

MILLVALE.—Mr. James Grundy is now superintendent of the municipal water and light plant, and Mr. J. K. Weaver is chief engineer.

MECHANICSBURG.—Bids have been called for by the Council for lighting the city by electricity.

TARENTUM.—It has been voted to issue $37,000 in bonds for improvements to the lighting plant and the streets.

HAWLEY.—The following are the officers of the Hawley Electric Light & Power Company: President, Mr. I. F. Megargle; secretary and manager, Mr. S. Laines; treasurer, Mr. E. L. Schlager.

GALLITZIN.—The Gallitzin Electric Light Company is owned and controlled by the Pennsylvania Coal & Coke Company. Mr. D. P. Conrad is superintendent of the plant.

BLOOMSBURG.—It is the purpose of the Irondale Electric Light, Heat & Power Company, recently incorporated, to furnish electricity to the towns of Catawissa, Rupert and Danville, as well as Bloomsburg.

HANOVER.—A charter has been granted to the Hanover Electric Power & Heating Company, with a capital of $50,000. The company purposes furnishing electric power and steam heat from a centrally located plant.

SHENANDOAH.—The Shenandoah & Mahanoy City Light, Heat & Power Company has been incorporated with a capital of $75,000. Mr. David Graham, of Mahanoy City, is president, and Mr. W. T. Lee, of this city, is president.

MT. PLEASANT.—A charter has been applied for by the Hartigan Electric Light, Heat & Power Company to furnish electricity in this city for light, heat and power purposes. Messrs. John F. Hartigan and J. F. Kalp are among the directors.

CRESSON.—The Cresson Electric Light Company is owned and controlled by the Pennsylvania Coal & Coke Company. The plant is in charge of Mr. D. P. Conrad as superintendent, who is also superintendent of the Gallitzin plant, owned by the same company.

WILMERDING.—The United Electric Company of Wilmerding, organized a couple of months ago, has, on the agreement of the Council to extend the time for putting the proposed plant in operation, placed its order for two 200-h.p. engines and two 150-kw. generators to be installed in the plant upon its completion.

MEADEVILLE.—The following gentlemen have been elected officers of the People's Incandescent Light Company: President and manager, Mr. F. R. Shryock; vice-president, Mr. George D. Traim; secretary, Mr. Cyrus Lee; treasurer, Mr. H. H. Thompson, and chief engineer, Mr. George D. Schreiber.

MAHANOY CITY.—A charter has been applied for by the Economy Light, Heat & Power Company to furnish electricity for light, heat and power in Mahanoy City, Mahanoy Township and Delano Township. Among the incorporators are Mr. Harrison Ball and Mr. John Matthias, of this city; Mr. P. D. Jones, of Hazleton, and F. P. Spiese, of Tamaqua.

RIDLEY PARK.—The Ridley Creek Electrical Supply Company has purchased the John G. Smedley farm in Willistown Township, Chester County, upon which there is a water power of sufficient energy to produce abundant electricity. It is the purpose of the company to furnish light and power to Duffryn Mawr, Paoli, Malvern and other points along the Pennsylvania Railroad.

ELLWOOD CITY.—The Ellwood Power Company, which recently began operations here, is supplying the city lighting plant with current and will establish sub-stations in West Pittsburg and Zelenople, which will necessitate the erection of 24 miles of high-tension transmission line. The officers of the company are: Mr. A. C. Fry, president; Mr. S. A. Rolofs, secretary and treasurer, and Mr. T. K. Bevington, manager and superintendent.

LEBANON.—Mr. Frank C. Wright, superintendent of the Edison Electric Illuminating Company, has been making extensive improvements in line work the past few weeks. The alternating-current line has been extended out Seventh Street to the Iron City Brewery in order to furnish it with power and light; also the shoe factory and the New Lebanon Brewery with light. A line has been run from Seventh Street out Canal Street to Fourth Street for the purpose of supplying twelve new customers who have been secured in the Independent district with lighting current. All of the new machinery at the plant has been installed and is in operation, including two new reserve Edison machines for the commercial lighting of stores, which will obviate the possibility of a break-down. The company has closed two contracts for current for lighting and power purposes, one with the Lebanon Chain Works for which two 30-h.p. three-phase alternating-current motors will be used, and the other for 10 horse-power to be supplied to the new scrap yard. The contract with the Lackawanna Iron & Steel Company for power and lighting current has been renewed for the balance of the year.

SOUTH CAROLINA.

NEWBERRY.—It has been proposed to expend $5000 for improving the electric light plant of the town.

ANDERSON.—A company has been organized in this city to develop the Hatton Shoals on the Tugaloo River. A large electric power plant will be erected.

DARLINGTON.—The officers of the Darlington Light & Water Company are as follows: Mr. W. M. Haynsworth, president and treasurer; Mr. A. G. Haynsworth, secretary; Mr. R. B. Haynsworth, manager, and Mr. C. Hatchel, chief engineer.

ROCK HILL.—The changes in progress at the plant of the Catawba Power Company will shortly

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

be completed, when the company will be prepared to furnish current for power purposes during the day. The new machinery is being installed, and the company expects to carry a full stock of electrical appliances and a complete line of motors.

BATESBURG.—An election was recently held to vote on the proposition to bond the town in a sum not exceeding $20,000 for water works, electric lights and general road improvements. The bond issue was carried by a vote of 75 to 18, and the following commissioners were elected to arrange for issuing the bonds, etc.: The Hon. W. H. Timmerman, Mr. L. D. Cullum and Mr. L. B. Kernaghan.

SOUTH DAKOTA.

SPRINGFIELD.—Mr. J. L. Turner is now manager of the Artesian Company of this place.

MITCHELL.—The Electric Company, of this town, expects to make a change in its lighting system from arc to alternating-current series, and will increase the capacity of the plant.

TENNESSEE.

COLUMBIA.—The Columbia Water & Light Company is arranging to add new equipment for supplying a day service.

HUNTINGDON.—Mr. Ernest M. Norman has been re-elected superintendent of the Huntingdon Electric Light & Water Works for the ensuing year.

TRACY CITY.—The Tracy City Electric Light & Power Company has been incorporated, with a capital of $5000, by Samuel and Henry Werner, for the purpose of furnishing electricity for light and heat in this city.

NASHVILLE.—Three of the fifteen lightning arresters at the new power house of the Nashville Railway & Light Company were recently destroyed by lightning. But for these arresters, the damage, which was only $15 or $20, might have amounted to several thousand dollars. The lights were extinguished for about thirty seconds when the bolt struck the power house.

CHATTANOOGA.—The City Council has agreed to a bond issue of $1,000,000 for the purpose of constructing an electric power plant at the Suck, thirteen miles below the city on Tennessee River. The plant will be erected and controlled by private parties, who will pay the city 5 per cent. for the use of the capital to be derived from floating the bonds upon which the city will pay interest. The city reserves the right to purchase the plant at the expiration of fifty years, and during the existence of the contract is given 500 free lights.

TEXAS.

BELTON.—Mr. F. Fairweather is now secretary and manager of the Belton Electric Company.

DE LEON.—Reports state that an electric light plant is to be constructed here by Mr. C. L. Rucker.

LEONARD.—The Electric Light & Ice Company was recently incorporated with a capital stock of $15,000.

SAN ANTONIO.—Bids are wanted by this city for a franchise to construct an electric light, gas and power plant.

COMFORT.—Mr. Max A. Flach is superintendent of the electric light plant here, of which Mr. Ernst Flach is proprietor.

COLUMBUS.—An effort is being made toward the establishment of an electric power plant on the Colorado River at this point.

MATTHEWS CITY.—Articles of incorporation have been filed by the Matthews City Lighting Company, with a capital of $20,000.

NEW BRAUNFELS.—The Landa Electric Light & Power Company expects to rebuild one of its lines at an early date and make other improvements in its system.

BROWNSVILLE.—Judge James B. Wells has been granted a franchise by the City Council for the construction of an electric light plant and water works. He will also establish an electric light plant at Matamoras, Mexico.

EL PASO.—The officers of the International Light & Power Company, which operates plants in this city and Juarez, Mexico, are as follows: President, Mr. Lee Clark; vice-president, Mr. H. T. Edgar; secretary, Mr. John Franklin; treasurer, Mr. A. S. Pratt; superintendent, Mr. Howell Scott, and chief engineer, Mr. John Nelson.

SHERMAN.—The Sherman Gas & Electric Company has been organized in this city, with a capital stock of $200,000, for the purpose of establishing an electric light and power plant. The incorporators of the company are Messrs. J. F. Strickland, W. R. Brents and C. N. Roberts, of Sherman; Mr. R. B. Sticher, of Cleburne, and Messrs. Osie Goodwin, M. B. Templeton and J. L. Penn, of Waxahachie.

EL PASO.—The Mimbres River Water Company recently filed articles of incorporation. The company is capitalized at $2,000,000 and was incorporated for the purpose of carrying on the business of a water company, to build reservoirs and canals to supply water for irrigation, public and private use, and to construct electric light and power plants for domestic and public uses in El Paso and other communities. The incorporators are Messrs. George W. and James S. Delamater, of Pittsburg, Pa.; Mr. Allen G. Kennedy, of Santa Fe, N. M., and Mr. Edward L. Medler, of Albuquerque, N. M. The preliminary arrangements for the construction of large water works to supply this city have been completed. The drafts and plans for the plant and pipe line are being prepared under the direction of Mr. John C. Balcomb. The entire works are to be completed within two years.

UTAH.

LOGAN.—Garff & Sons are negotiating with the City Council to establish and equip an electric light plant, the plant to be sold to the city after four years.

SALT LAKE CITY.—The Pan Power & Electric Company of Utah has been organized in this city, with a capital stock of $10,000. Mr. William D. Cameron is president of the company, and Mr. James A. Mahon, secretary.

OGDEN.—Local reports state that the Utah Light & Railway Company, of Salt Lake City, expects soon to establish a sub-station near the center of this city in order to improve the electric light and power supply service and to prevent the loss of electric energy due to low-voltage transmission. The transformers and other machinery in the company's present plant were recently damaged to the extent of $15,000 by an electrical storm.

SALT LAKE CITY.—The merger of the Consolidated Railway & Power Company, the Utah Company and the Utah Light & Power Company was recently effected and the company incorporated with a capital stock of $10,000,000. The following are its officers: President, Mr. Joseph F. Smith; first vice-president, Mr. John R. Winder; second vice-president, Mr. Joseph S. Wells; treasurer, Mr. Lewis H. Hills; secretary and general manager, Mr. Robert S. Campbell, and assistant secretary, Mr. John M. Whitaker.

VERMONT.

MANCHESTER.—The following are the officers of the Manchester Light & Power Company: President, Mr. John Marsden, Utica, N. Y.; vice-president and treasurer, Mr. George Smith, Manchester; secretary, Mr. A. V. Orvis, Manchester; manager, Mr. A. B. Marsden, Manchester Centre; chief engineer, Mr. Louis Borman.

VIRGINIA.

WEST POINT.—Bids were recently received by the Town Council for the sale of a franchise to light the town by electricity.

TAZEWELL.—Articles of incorporation have been filed by the Tazewell Electric Light & Power Company, indicating a capital stock of $15,000. Mr. Joseph S. Moss is president of the company.

BLACKWOOD.—The necessary current for lighting the town of Blackwood is supplied by the Blackwood Coal & Coke Company. Mr. J. L. Hetler is superintendent of the lighting plant of the company.

HARRISONBURG.—It has been decided by the Council to install a municipal electric light plant which will cost about $70,000. The power for operating the plant will be obtained from the Shenandoah River.

WAYNESBORO.—The Waynesboro Electric Light Company recently purchased a new dynamo and new transformers for its lighting plant, and is increasing its service by the addition of a few short residential lines.

FREDERICKSBURG.—The new purchasers of the water power business here have organized by electing Mr. Joseph Swift, of Wilmington, Del., president, who with New York capitalists and Mr. E. J. Cartwright, of this city, form the directorate. The minimum capital is $50,000, with a maximum of $200,000.

NORFOLK.—In view of the rejection by the Council of the Fentress application for a heating and lighting franchise, the Norfolk Railway & Light Company has announced a reduction of $16\frac{2}{3}$ per cent. to the general public, to the city pumping stations and on any other city lights not included in contracts. The company has also submitted a proposition to enter into an agreement with the Council that the rates for lighting and power be revised at periods of five years hereafter, provided the Council in the meantime will protect the company in its franchises for lighting, the revision of rates to be agreed upon between the Council and the company.

DANVILLE.—The improvements recently made at the municipal electric light plant at a cost of about $9500 have been completed and the entire plant is now in operation. The plant is arranged for both water and steam power, so that whenever the water power becomes inadequate to the requirements the steam machinery can be brought into service. The equipment includes a 300-h.p. engine driving a generator of corresponding size. The addition which was made to the old plant is 22x50 feet and the boiler room is 14x28 feet. The present net income of the plant is about $8000 a year, and it is thought that the amount can be doubled within the next year or so if the council can be induced to string the necessary wires. Superintendent Talbot is making an effort to have this done.

WASHINGTON.

PUYALLUP.—The Puyallup Light & Water Power Company is considering extensive improvements to its system.

BALLARD.—The Ballard Electric Company will shortly begin work on its new plant. A 250-kw. machine has been ordered.

COLFAX.—The Whitman Electric Railway Company is taking preliminary steps toward the installation of an electric power plant.

PORT ANGELES.—The City Council has awarded the contract for erecting a power house for an electric light plant to Rich & Freeman.

BALLARD.—Press reports state that Mr. H. A. Starkey has failed to accept the franchise recently granted him for an electric light plant.

VANCOUVER BARRACKS.—The electric companies have been requested to submit bids for furnishing a complete lighting system to Ft. Wright, Wash.

NOOKSACK.—Recent reports are to the effect that the Washington Mining & Development Company, of Seattle, is arranging for the installation of an electric plant near this city.

NORTH YAKIMA.—The city council has repealed the franchise of the Northwestern Water & Light Company, which was granted to the company last fall for a term of 37 years.

WALLA WALLA.—Mr. Heinrich Hillman is asking the City Council for a franchise for the construction of a street railway and for the purpose of erecting and maintaining a general electric light and power plant.

SNOHOMISH.—The plant of the Electric Light & Power Company has been destroyed by fire, involving a loss of about $6000. A dynamo has been secured and partial service is being provided until the plant can be rebuilt.

MARYSVILLE.—The Marysville Light & Water Company is said to be engaged in the construction of a tunnel from the northwest shore of Lake Stevens in the direction of Marysville. A large

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

dam is also being built and the control of the Little Pilchuck has been secured.

WATERVILLE.—The city attorney has been instructed to draw up a contract between the city and George H. Gray & Son to furnish electric power to the city. It is understool that the machinery for the plant has been ordered. Messrs. George H. Gray & Son also operate a plant at Enteat, Wash., of which Mr. G. H. Gray is manager.

PORT TOWNSEND.—Mr. J. M. Kincaid is now chief engineer for the Townsend Gas & Electric Company. Messrs. S. E. Christian and E. D. Sturrock, the former engineers, have started an electrical store under the firm name of the Pacific Electric Company for the purpose of furnishing supplies to the numerous isolated plants in the vicinity of Port Townsend.

WEST VIRGINIA.

WHEELING.—Mr. H. H. Underwood is superintendent of the municipal electric light plant of this city.

MOUNDSVILLE.—The council has granted a franchise to the Moundsville Electric Company. A fifty-year extension was granted, and the company is understood to have the plans ready for a $25,000 plant.

GRAFTON.—Mr. T. P. Kenny, superintendent of the municipal electric plant, states that the equipment consists of one Brush arc generator developing 8500 volts at 500 r.p.m., one Wood arc generator developing 5000 volts at 800 r.p.m., and one Russell engine of 200 horse-power. The plant supplies current for 100 Adams-Bagnall arc lamps and 75 Wood arc lamps.

WHEELING.—The extensive improvements now under way at the plant of the Bellaire Light & Power Company involve an expenditure of nearly $100,000, and will include the installation of a 450-h.p. 4-valve Hamilton-Corliss engine and a 300-kw. G. E. alternator. The capacity of the plant will be nearly doubled, and as the new equipment will make it a duplicate plant the company will be in a position to cope with any emergency that may arise. The present voltage of 1100 will be raised to 2200, and regulators will be installed to insure uniform voltage at all times.

WISCONSIN.

TOMAHAWK.—Mr. V. E. Extrom has been made superintendent of the Electric Light & Telephone Company.

COLUMBUS.—Mr. W. E. Smith is now superintendent and manager of the municipal electric light plant and water works.

LADYSMITH.—The Ladysmith Light & Power Company is arranging for the installation of series arc lights and the development of water power.

WITTENBERG.—It is understood that the contract for an electric light plant to cost about $10,000 has been awarded the Central Construction Company, Oshkosh, Wis.

SUN PRAIRIE.—The Sun Prairie Electric Lighting Company, of which Mr. C. B. Hayden is president, contemplates the construction of twelve miles of transmission line.

BERLIN.—Mr. H. C. Hullinger has been elected president of the Berlin Lighting, Heating & Power Company which has increased its capital stock to $100,000.

MARSHFIELD.—Mr. R. L. Kraus is interested in the formation of a stock company for the purpose of developing electric power from the dam of the Consolidated Water Power & Paper Company.

BERLIN.—The council has called for bids for furnishing and providing on a moonlight schedule 46 arc street lamps for a term of from five to ten years from June 1, 1905, and such additional lamps as the city may require from time to time.

MILWAUKEE.—The City Council is considering the question of issuing bonds to the amount of $150,000 for the construction of a municipal electric light plant. A statement submitted by the City Comptroller showed that it cost the city $256,546.14 to light the streets and public buildings during the year 1903.

NEW RICHMOND.—The Apple River Power Company has begun active work on the construction of a second electric power transmission plant near Somerset. Foundations have just been completed at the present plant for another 300-hp. dynamo, and when the second plant is in operation the company, which now lights New Richmond and pumps the water, will also furnish light and power for Stillwater.

ANTIGO.—The plant of the Antigo Electric Light & Power Company was recently destroyed by fire. The loss on machinery is estimated at $20,000 and the indirect loss will also be large, as the city was without light until arrangements could be made for temporary power and light and many small factories were compelled to shut down for lack of power. All the local newspapers were also put out of business temporarily for the same reason.

WYOMING.

LARAMIE.—The council is considering the matter of installing a municipal electric light plant, and City Clerk David McCullagh writes that the city would like to correspond with parties in regard to the construction of such a plant.

CANADA.

VICTORIA, B. C.—The Elsie Lake Power Company, Ltd., has been incorporated with a capital stock of $10,000.

GRANDIN, SASKATCHEWAN.—The dam on the Saskatchewan River, owned by the Grandin Electric Power Company, was recently washed away.

MITCHELL, ONT.—It is stated that about $10,000 will be expended by the city authorities for improvements to the water works and electric light plant.

RAT PORTAGE, ONT.—The Municipal Electric Light Company, of which Mr. G. L. Mattice is manager, contemplates the erection of a new power station in the near future.

ST. MARYS, ONT.—The Corporation of St. Marys anticipates installing an entire new equipment of machinery in the fall. Mr. T. R. Waugh is superintendent of the plant.

RICHELIEU VILLAGE, QUE.—This village is now furnished with light by the Montreal Light, Heat & Power Company. Mr. J. W. Fleet is superintendent of the local plant.

TRURO, N. S.—The Chambers Electric Light & Power Company has increased its capital stock from $60,000 to $100,000, fully paid in. Mr. S. G. Chambers is president and manager.

The officers of the company are as follows: Mr. W. H. Coleman, of Andover, Mass., president; Mr. L. A. Taylor, secretary, treasurer and manager, and Mr. W. C. Bean, superintendent.

NORTH HATLEY, QUE.—The plant of the Eastern Townships Electric Company is now furnishing lighting current to North Hatley, Waterville, Compton, Lenoxville, Eutis and Capeton.

NANAIMO, B. C.—The Nanaimo Electric Light Company is arranging to harness the waters of the mill stream and will erect a new power house and plant to supersede the present plant. Contracts aggregating $15,000 have been let.

FORT STEELE.—The Elk River Power & Light Company has started work at Elk River Falls and will proceed to install a large power plant immediately. The company expects to furnish power to all the industries in the Crow's Nest Pass.

BRANDON, MAN.—The Western Light & Power Company, with a capital stock of $300,000, has been granted a charter for the purpose of installing an electric plant on the Assiniboine River. Messrs. J. M. Robinson and John Russell, of Brandon, are among the incorporators.

WINNIPEG, MAN.—In a recent report of the city electrician to the Civic Fire, Water and Light Committee, it was suggested that it might be well for the city to consider the building of municipally-owned conduit systems wherein various systems of wires could be carried.

STAYNER, ONT.—Mr. John Knox, proprietor of the electric light plant of this city, states that it is his intention soon to develop water power for the operation of his plant. He also expects to build six miles of transmission line for the transmission of current for lighting and power purposes.

OTTAWA, ONT.—Although the citizens of Ottawa voted two years ago for a municipal lighting system, the City Council recently awarded the contract for lighting the city for a term of ten years to the Ottawa Electric Company. The contract is for $52 per light, which is a reduction of $13 per lamp from the old contract. According to the report of experts the city could do its own lighting for $38 per lamp per year.

MEXICO.

LEON, GUANAJUATO.—Bids have been requested for lighting the city by electricity.

MONTEREY.—The Monterey Light & Power Company expects to expend $150,000 in installing new machinery.

CHIHUAHUA, CHIHUAHUA.—The Compania Industrial Mexicana is making extensions to its present system for power service.

AGUASCALIENTES. — The Aguascalientes Light & Power Company is now lighting the city by means of its two new 50-kw. De Laval turbine-alternators.

VERA CRUZ, VERA CRUZ.—The service of the lighting system in this city is to be increased, for which purpose an order for an additional 500-kw. machine has just been placed.

GUAYNOPITA, CHIHUAHUA.—Mr. J. W. Taylor, of El Paso, Texas, is primarily concerned in a project for the construction of a large electric light and power plant in this city, to be operated by water power.

PUEBLA, PUEBLA.—The City Council has extended the contract of the local electric light and power company for furnishing the city with electric light for a period of twenty-five years on the condition that the capacity of the plant be increased.

YOPIA, DURANGO.—The Mexican Government has received an application from Miguel Morga for a concession permitting him to utilize the waters of the Sobrices River for the operation of a large electric light and power plant which he proposes to build.

JALAPA, VERA CRUZ.—Mr. George Greenwood, for several years superintendent and chief engineer for the Jalapa Railway & Power Company, has been appointed representative of the General Electric Company's interests on the Pacific coast of Mexico.

GUANAJUATO, GUANAJUATO.—A German company has applied to the municipal authorities for a franchise to establish an electric light and power plant in this city. The franchise of the company now supplying the city with electric light and power will expire in August.

MATAMORAS, TAMAULIPAS.—The City Council has granted a franchise to Mr. James B. Wells, of Brownsville, Texas, for the construction of an electric light plant and water works. Contracts are to be let at once for the construction, materials, machinery, etc.

GUADALAJARA.—The contract for the construction and equipment of a water-power plant of 1000 horse-power capacity in this state has just been let. The equipment will include three alternating-current generators of 250-kw. capacity each for direct-connection to water turbines. The transmission line will be about fifteen miles long.

ACAYUCAN, VERA CRUZ.—Mr. Antonio A. Moll is interested in a project by which it is proposed to utilize the waters of the River Ozolonpam, in the southern part of this state, for generating electrical energy to be transmitted to various plantations operated by Americans in that section. It is proposed to use 10,000 liters of water per second.

MEXICO CITY.—Work is progressing on the Necaxa plant of the Mexican Light & Power Company, which is engaged in building the Necaxa-Mexico City-El Oro power transmission system. The plant will have an initial capacity of 45,000 horse-power, with an ultimate capacity for developing 80,000 horse-power. It is expected that contracts for the equipment, etc., will be given out shortly.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

American Electrician.

Vol. XVI. New York, August, 1904. No. 8.

LIGHTING PLANT OF A LARGE OFFICE BUILDING.

THE GENERATING EQUIPMENT OF THE WHITEHALL BUILDING, NEW YORK.

A COMPLETE electric lighting plant in a modern office building is exemplified by that of the new Whitehall Building in New York City. This fire-proof structure occupies the 180-ft. block running from Washington Street to West Street on Battery Place facing Battery Park and New York Harbor, and is 20 stories high with about 8200 square feet of floor space on each floor. The power plant is divided into two parts: one consisting of three 12 x 18½ x 10¼ x 18 pumps which operate the six hydraulic passenger and freight elevators and supply hot water to the whole building; the other consisting of three direct-connected electric units driven by engines having an aggregate capacity of 615 horse-power.

The lighting plant is located in the southeast corner of the basement in a room 32 x 26 feet. The smallest unit is a 75-kw. generator driven by a 125-h.p. engine. The second machine is a 125-kw. generator coupled to a 190-h.p. engine, while the third and largest unit is of 200 kilowatts capacity. All of the generators are 240-volt direct-current compound-wound, engine-type machines built by the Crocker-Wheeler Company, of Ampere, N. J., and the engines to which they are direct-connected were supplied by the Harrisburg Foundry & Machine Works, of Harrisburg, Pa.

In the generators, the magnet frame is a cast iron ring of patented channel section construction, divided horizontally, into which the eight steel poles are cast welded. The field coils are divided into several sections each taped and varnished as a unit, and separated so as to increase the heat radiating facilities. The brush rigging is constructed so that individual adjustment of the brushes is possible. A noticeably large air-gap is left between the pole shoe and the armature with the object of minimizing the field distortion and the unbalancing effect of the armature getting in time slightly out of center with respect to the field.

The three engines are of similar construction. The shaft of each is supported with one bearing on the side of the frame and one on a pedestal supported by an extension of the engine base beyond the generator. It is thus held in positive alignment with the reciprocating parts. The crank-pin, cross head, pin and shoes are enclosed in an oil hood.

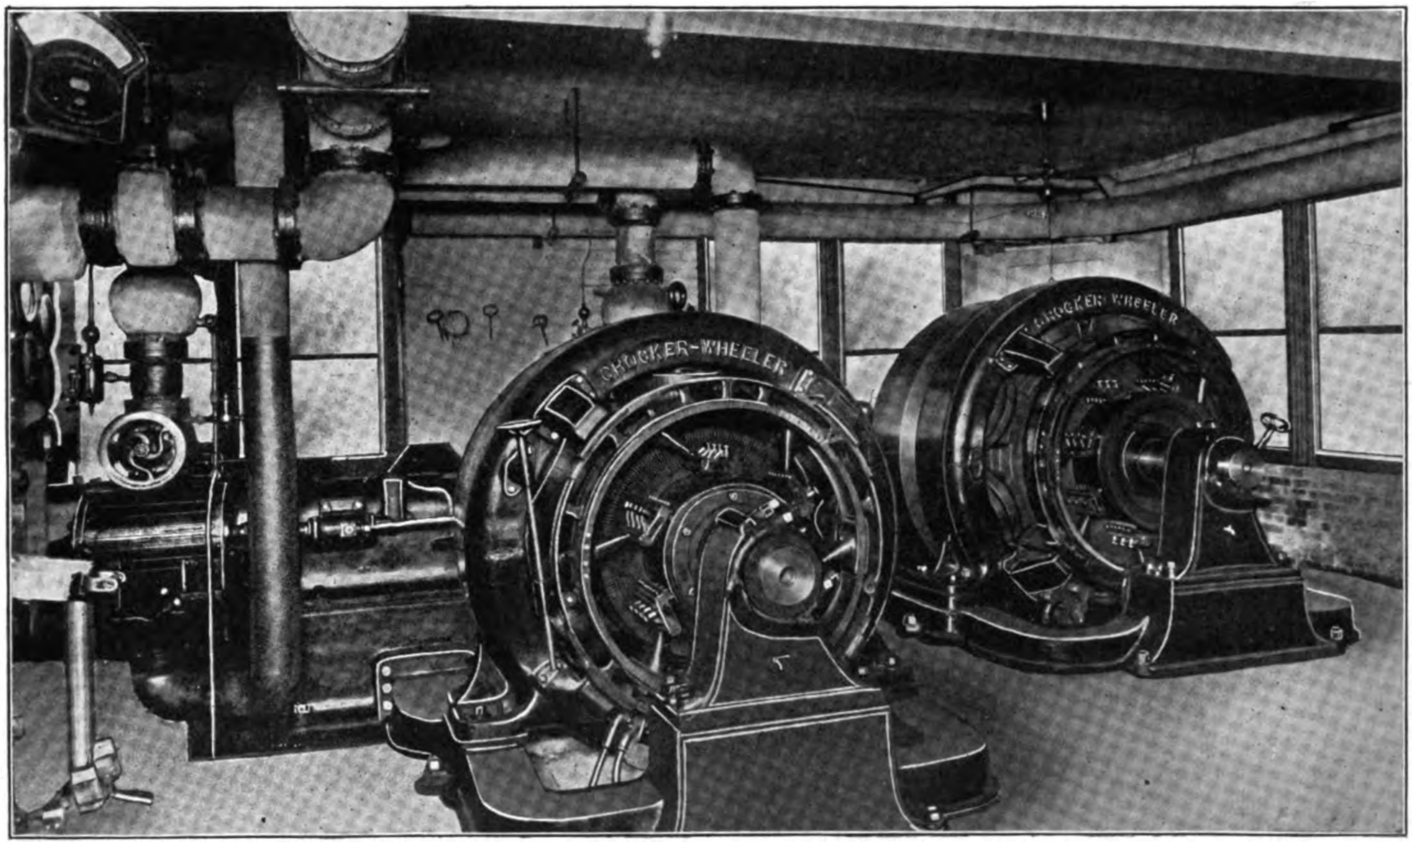


FIG. I.—VIEW OF WHITEHALL BUILDING ENGINE ROOM, SHOWING SMALLER GENERATORS.

Separated from the engine room by a brick wall and some distance away owing to the restrictions of space, is the boiler plant. This consists of three Heine safety water-tube boilers, widely separated, two of which are of 250 horse-power and the other of 210 horse-power capacity. Their normal working pressure is 150 pounds. They are hand stoked and are fitted with improved Treadwell grates. The coal bunkers which extend nearly three-quarters of the length of the building on the north side have a capacity of about 300 tons of rice coal. An elevator to the sidewalk on the Washington Street side lifts the ashes to the street.

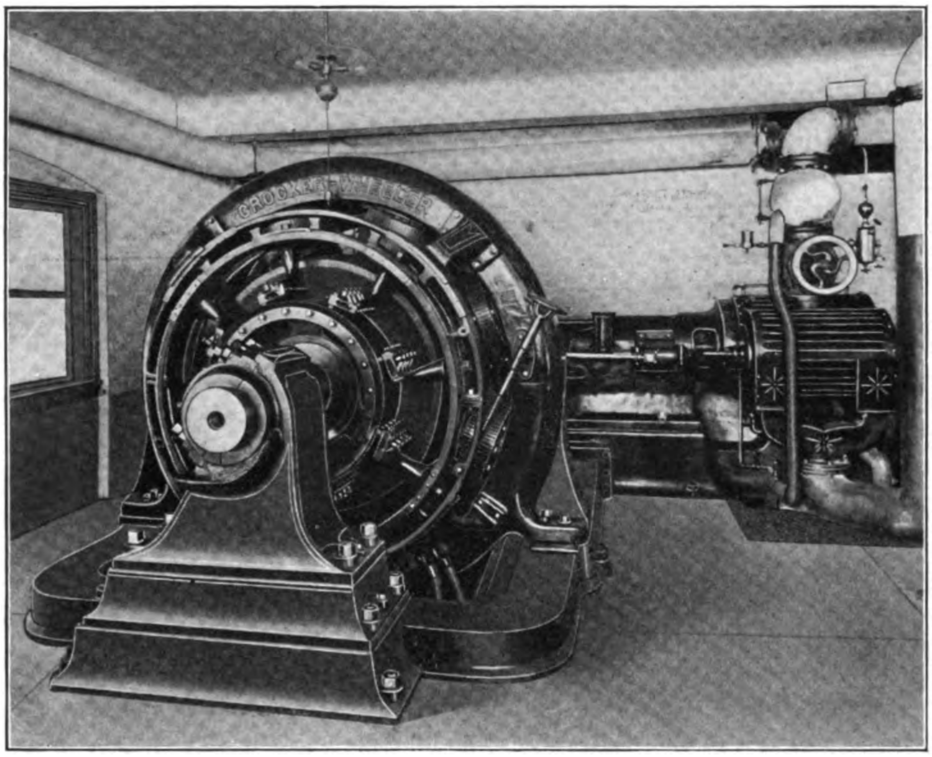

FIG. 2.—LARGE GENERATING UNIT IN WHITEHALL BUILDING.

For supplying steam to the engines there are two main lines of steam piping, asbestos covered, one of which is an auxiliary line which is used only when repairs are being made on the main line. The largest engine takes steam direct from the main 10-in. line through a 7-in. copper bend having a 3-ft. radius. The smaller engines take steam from an auxiliary 7-in. line through 6-in. and 4½-in. copper bends respectively. 8-in., 7-in. and 4½-in. exhaust pipes from the engines connect with a 14-in. main exhaust running to the roof.

Feed-water is supplied through two 7½ x 4½ x 6-in. pumps, but before passing into the boiler it is filtered by a Ward filter of 500 gallons capacity. This is composed of 8 cast iron cylinders 12 inches in diameter and 7 feet over all, and is fitted with special cast zinc bars and filled with animal charcoal. The filter is provided with a removable outside strainer and has a 3-in. feed-water inlet and a 3-in. outlet. It is built for a working pressure of 150 pounds. A 850-h.p. closed feed-water heater of the Berryman type is connected in the feed-water line.

Connected to the main exhaust line is a "Utility" muffler tank 4 ft. 6 in. in diameter and 10 feet long. This contains two separate compartments; one for the exhaust and the other for the high-pressure drips, with an automatic device to control the action of the high-pressure drip pump. A 14-in. inlet and a 14-in. outlet is provided for the exhaust steam. The blow-off tank is 4 ft. by 8 ft. long, and is provided with a cooling coil of seamless brass pipe 3 inches in diameter.

The suctions from the muffler and suction tank are connected to the boiler-feed and house pumps, which are cross-connected in such a manner that either one or more of the pumps can be used to pump water from the main cold water suction tank or the muffler tank and discharge either to the boilers or house tank. The discharge pipes from the boiler feed-pumps are connected to the supply valves on each boiler. All the drips from the engines and pump cylinders and exhaust piping before passing through the muffler tank and oil separator, and the other drips having oil or foreign matter in them are connected to the drip tank through traps. These drips are carried to the drip tank and connected with a check valve on each separate line having different pressures and arranged so that there is no danger of the high-pressure drips interfering with the operation of the low-pressure drips. The drips from the steam separators and any other drips having clean water in them are trapped through high-pressure traps into the muffler tank.

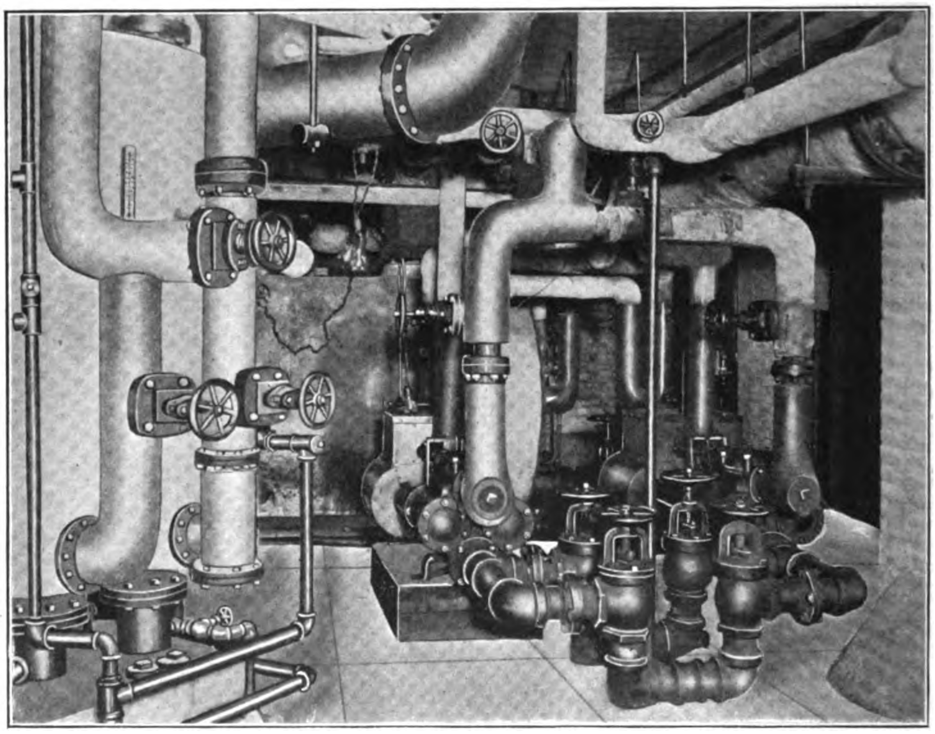

FIG. 3.—FEED WATER PUMPS AND AUXILIARY APPARATUS.

The normal load of the plant is about 100 amperes; but when the days are short this is increased to 700 amperes and has been as heavy as 800 amperes. The switchboard is 7½ feet high by 10 feet wide and consists of five white marble panels. Beginning at the left, the first is a feeder panel with nine switches controlling the lights in the west side of the building, of these three have a capacity of 100 amperes, three of 150 amperes and three of 200 amperes. The second is also a feeder panel for the lights in the east end of the building; the switches being identical with those in the other feeder panel; it is supplied with a Weston voltmeter.

The three remaining and somewhat narrower panels are the generator panels. The first of the three is connected with a 1200-ampere Weston ammeter, a pilot lamp, a voltmeter switch, a Ward Leonard rheostat, an 800-ampere three-pole single-throw switch, and an 800 ampere single-pole I.T.E. circuit-breaker. The next, for the 125-kw. generator, is fitted with a 700-ampere

Weston ammeter, a pilot lamp, a Ward Leonard rheostat, a 600 ampere three-pole single-throw switch, and a 500-ampere single-pole I.T.E. circuit-breaker. The last panel is connected with the smallest generator, of 75-kw. capacity. It is equipped with a 600-ampere Weston ammeter, a pilot lamp, a voltmeter, a Ward Leonard rheostat, a 400-ampere three-pole single-throw switch and a 400-ampere single-pole I.T.E. circuit breaker. Swung on a bracket from the last panel is a Weston station voltmeter. The switchboard is set up four feet from the north wall of the room and access to the rear is had through a grille door at each end.

The current is used almost entirely for lighting. This is done on the two-wire system and over 6000 230-volt incandescent lamps are connected in circuit. The panel boxes in the basement and on the first and second floors are supplied with current from the switchboard through six 100-ampere double-pole single-throw switches and four No. 5, six No. 6 and two No. 8 cables. The distributing panels supplying current from the third to the eighteenth floor are supplied through six 200-ampere double-pole single-throw switches and two No. 0000 cables and two 200,000-cir.-mil cables to the fifth floor; two No. 0000 cables and two 300,000-cir.-mil cables to the tenth floor, and two 300,000-cir.-mil and two 350,000-cir.-mil cables to the fifteenth floor. Sub-feeders to the other floors are of No. 4 cables. Above the eighteenth floor, two 150-ampere switches supply the distributing boxes on the nineteenth floor through two 250,000-cir-mil and two 200,000-cir.-mil cables; sub-feeders to the eighteenth and twentieth floors being of No. 8 cable. All of the cable is, of course, encased in suitable iron conduit.

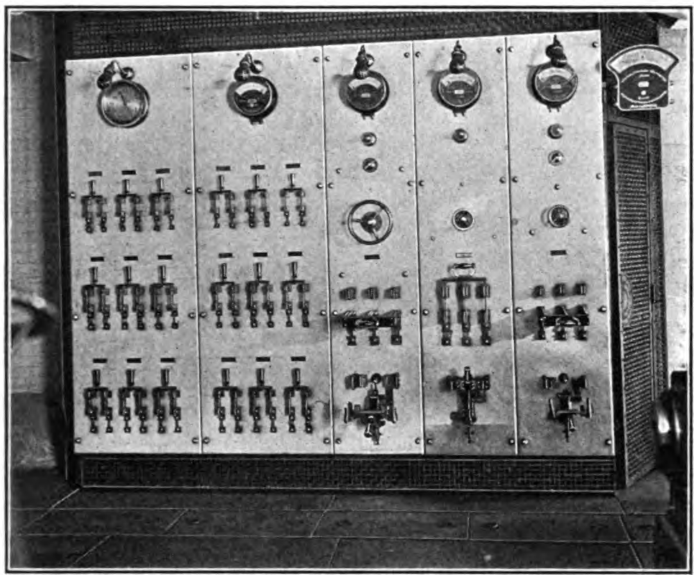

FIG. 4.—SWITCHBOARD.

The entire plant is in charge of Mr. George A. Traver, superintendent. The constructing engineers were the George A. Fuller Company and the steam piping was installed by the New York Steam Fitting Company.

SYNOPSIS OF FUNDAMENTALS PERTAINING TO SPEED VARIATIONS IN DIRECT-CURRENT MOTORS AND DETAILS OF A MOTOR HAVING A WIDE SPEED RANGE

BY ALBERT F. HEMINGWAY.

The elementary quantities regulating the speed of direct-current electric motors are, for the shunt type diagram, Fig. 1, the circuit potential V, volume of field flux N, and the armature surface conductors, W, for the series type V, N, W, and the current I flowing through the motor. The substance of the following relates briefly to the character and limitations in each instance when such quantities are employed to effect speed variations, supplemented with a description of the leading features of a type of motor originated especially with a view to a wide range of speed variation and simple control, in which a serviceable speed range is obtained through a divided magnetic circuit and separated armature portions which operate mutually in effecting the lower speed and differentially effecting the higher.

As the speed of a motor varies proportionately with the circuit potential V, variations in V result in corresponding variations in speed. For instance, if the potential of a circuit upon which a 10-h.p. motor is operating be 200 volts, and if for consideration this potential is diminished 75 per cent to 50 volts, the speed, and still further, the power will be diminished a corresponding amount. If the character of service be such that constant power is required at all periods of the speed range, the horse-power of the motor must be determined according to the lowest speed and potential. If at 50 volts the rating of the motor is to be 10 horse-power, this will increase with the increase of potential and at 200 volts the motor will develop 40 horse-power.

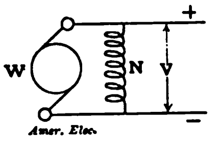

FIG. 1.

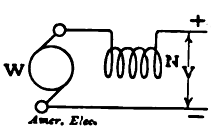

FIG. 2.

In the earlier rheostat method of providing a variable potential through variations in a resistance inserted in the armature circuit, the waste of energy is directly proportional to the diminution of potential; that is, if a 200-volt potential be diminished 75% to 50 volts, the loss is 75%.

A more highly developed and efficient means of obtaining variable potentials is through the use of a number of circuits having a variety of potentials, familiarly known as multi-voltage systems. With two generators three potentials are available; with three generators, six potentials; with four generators, ten potentials; the different motor speeds being obtained by operating the motor on one or another of the circuits.

As the speed of a motor varies inversely with variations in the field flux density N, variations in N result in corresponding variations in speed. As the current flowing through the armature produces a counteracting flux N', which beyond 50 per cent or 75 per cent in its relative value of N creates prohibitive conditions followed by a distortion of the commutating fringe, the region of which is indicated in lines X, Y in Fig. 3, the speed which is varied in this manner has a very limited range without arcing at the commutator, so that manual attendance in adjusting the commutator brushes to coincide with the shifting of the imaginary point X, Y is necessary. If, for example, in a certain motor it is assumed that the ratio of N to N' at the highest speed and maximum load be 1.5, below which arcing at the commutator commences, and that the speed range is to be as 1 to 3, the ratio of N to N' at the lowest speed must then be as 1 to 1.5×3, assuming that the magnet, *i. e.*, the field structure, be tripled in sectional area. The thrice extra flux to be conducted by the armature core requires that its sectional area must also be increased, which, in addition to the increased proportions of the field poles, conjoins to increase both the diameter and length of the armature; consequently each armature turn of wire encircles a greater section of iron. The flux due to the armature ampere-turns increases directly with the section of iron within the coil, and the ratio of N to N' is but slightly increased due to the tripled dimensions; the facts in general being that the iron of the motor increases proportionately with the decrease of speed and the copper as the square of the ratio of variation. For instance, if the speed range be as 1 to 2, four times the

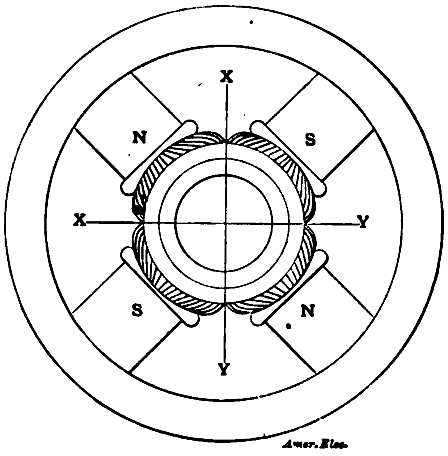

FIG. 3.

copper will be required and twice the iron, compared with a single-speed motor operating at the maximum velocity.

As the speed of a motor varies inversely with the number of armature conductors *W*, any variation in *W* produces corresponding variation in speed. The mechanical difficulties encountered alternating the series and parallel relation of conductors, *W*, to any great extent, upon a revolving armature, are practically insurmountable. Beyond one series and parallel combination through the use of two commutators, intricate and serious difficulties enter which place it out of consideration for the present. By joining two such commutators in series and parallel relation, the speed may be raised as the ratio of 1 to 2.

The series motor so generally employed in connection with the operation of electric railways derives its popularity over the shunt type from its ability to stand abnormal strains and submit to current overloads for short periods of time, the speed of a series motor varying with variations in the circuit potential, field flux and armature surface wires in a similar degree to that of the shunt type. The flexibility in the matter of strains and current over-loads is due in a measure to the fact that in a series motor the speed is sensitively altered with variations in current. In consequence of an excessive flow of current the speed is diminished, and as the power imposed by any given strain comprises the factors, torque and time, through a diminution in speed there is an adjustment of time co-operating with torque or current values. The extra strain, therefore, does not increase the horse-power result (torque × time). In this respect the ordinary shunt motor would prove fundamentally weak if applied in connection with a service of this character, from the fact that its field flux *N* remains constant, while the armature reactive flux *N'* varies with variations in the current passing through it. An abnormal current load thrown upon the armature of a shunt motor produces a magnetic field overpowering in its relation with the field flux; this is a prohibitive condition, resulting in improper commutation. With a series motor, the current that passes through the armature also passes through the field, thus supporting it automatically through all conditions of load and maintaining a fixed relation of armature flux *N'* to the field flux *N*. In consequence of this the position of the commutating brushes does not vary, and within reasonable limits the operation of a series motor does not cause any serious alarm as to arcing at the commutator. The momentary heating would have to be of some duration to realize evil results, but arcing at the commutator, if excessive, would be brief in manifesting its destructive effects.

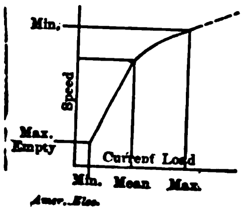

FIG. 4.

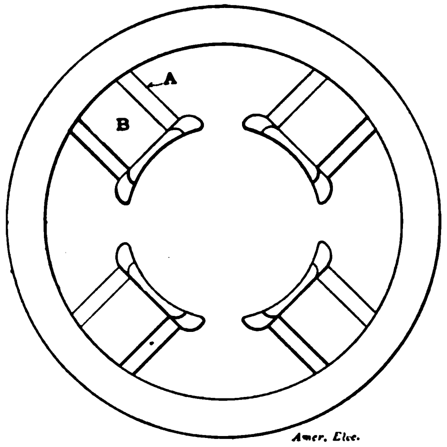

FIG. 5.

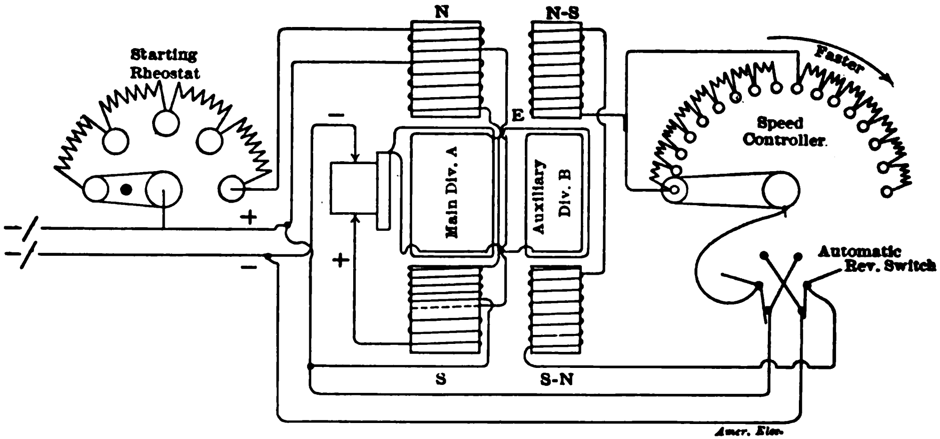

FIG. 6.

The series motor though characteristically suited for operating under abnormal strains, because of the inter-operating relation of armature and field, is entirely incompetent for a service such as driving the majority of factory tools or machines requiring sensitively graduated speeds and effected by current over-loads or sudden strains; the speed of a series motor varying inversely with variations in the current flowing through the armature, reference to which is graphically made by a representation of its saturation curve in Fig. 4. Between the minimum and mean current-load points of the abscissa the greatest variation occurs, while between the mean and maximum load points the speed is approximately uniform, indicating that if this condition of speed is desired the motor should continually operate at or above its mean load point when the iron of the motor is reaching saturation.

In the compound type of motor, which combines both the shunt and series windings, the saturation point *S* referred to is reached and maintained by the shunt winding. It is then evident that a great part of the advantages derived through the use of the series field winding, in respect to submitting to abnormal currents without arcing at the commutator, combines with the inherent speed constancy of the shunt type. The relation of armature flux *N'* to the magnetomotive force, ampere-turns, is kept approximately constant, depending, of course, upon the relation of armature-turns to field series turns.

Whenever speed variations are the result of varying the field density *N* in a compound-wound motor, though the range may be somewhat greater than in the shunt type, speed regulation will be found very poor and erratic. If on the other hand the speed be varied through some agency other than the field flux *N*, as for instance the circuit potential or armature surface conductors, or through the foregoing type of construction, the series winding may become of great assistance, especially when the magnetic circuit is to begin with brought up to saturation by the magnetomotive force of the shunt coils. The then variable magnetomotive force of the series coils serves to balance the relation of armature magnetomotive force to that of the field, and over-loads are possible without serious arcing at the commutator or speed irregularities.

If it were mechanically possible to arrange armature circuits so that various series and multiple combinations of armature surface conductors *W* could be formed upon a revolving armature, it would be, theoretically, an effectual means of obtaining speed variations in a motor operating on a potential of constant value. From the foregoing a constant or fixed potential shunt motor may have its speed varied by varying the field flux *N* or armature conductors *W*, but the inherent incapabilities of the former are quite fully exposed and the latter may be seriously involved with mechanical difficulties. In the form of motor here presented, speed variations are obtained through variations in the seat of counter electromotive force, analogous to variations in conductors *W*, due to the fact that each armature conductor forms part of a circuit a portion of which induces a counter e.m.f. that is variable and capable of being controlled through the field-flux variations of an auxiliary magnet yoke.

By reference to Fig. 5, it will be seen this motor is of the usual multi-polar form. The magnetic field structure is divided, the main division *A* and the auxiliary divisions *B* being indicated by the circuit sketch in Fig. 6. For convenience the description may refer to the armature as possessing but the one winding and core, though as shown in the circuit sketch the armature may possess two distinct divisions, an armature division for each magnetic circuit with a comparatively greater number of surface conductors on the armature of division *B* than there are on that of division *A*, the coils of each armature being connected in series; the coils when joined and completed form virtually but the one armature with more or less surface conductors on one portion than on the other.

As previously mentioned, speed variations are obtained by varying the seat of counter e.m.f. of the armature of division *B*, causing that portion to operate mutually with the main armature *A* in producing the lower speeds and differentially producing the higher, this being accomplished by varying and reversing the field flux of magnetic division *B*, thereby subjecting this armature portion to a variable and controlled counter e.m.f. As the resultant counter e.m.f. of the armature as a whole must remain nearly constant, depending upon the current passing through it, this is accomplished through a compensating adjustment of armature velocity; hence, the true cause of speed variation.

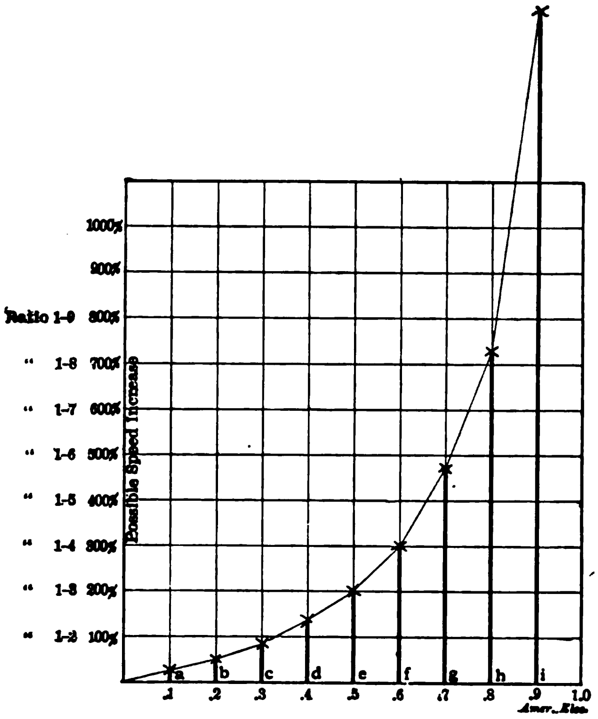

FIG. 7.

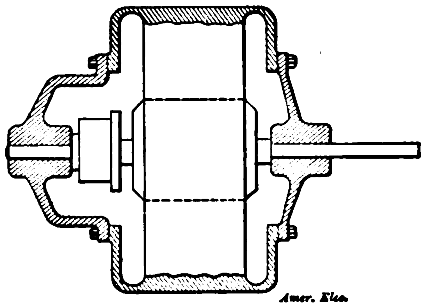

FIG. 8.

In the operation of this motor, the extent of speed range is dependent on the relative strength of division *B* and that of division *A*. If, for illustration, the armature conductors are the same in number for both divisions, and the magnetic circuits, *A* and *B*, are alike in strength, when operated differentially the speed range would become unreasonably great. Referring to the curve shown in Fig. 7, the heavy ordinate lines represent the extent of speed range corresponding with the values of the abscissa directly beneath each line, in terms of relative strength of *A* to *B*. From the curve, it will be seen that where *B* division is .9 in its relative strength of *A*, the line *i* extends upward beyond a reasonable extent, showing the relation of *B* to *A* is too great. At line *h* whence *B* is .8 in its relation to *A*, the possible maximum speed range is eight times the minimum—a ratio of 1 to 8. When *B* is one-half the strength of *A*, the speed range is as 1 to 3. In other words, if the speed when both divisions act mutually be 100 r.p.m., if *B* is .5 in its relation to *A* the maximum speed will reach 300 r.p.m. when the divisions act differentially.

Referring to Fig. 6, division *B* is varied in this manner and reversed and is further comparatively smaller in sectional area. The poles therefore are inclined to embrace the armature at a relatively smaller angle than those of *A*. The weak and erratic condition at times of the magnetism of division *B*, owing to the narrow pole faces, does not spread out far enough to influence the commutating pole tip magnetism of the poles of division *A*, which regulate as in any motor the proper points of setting the commutator brushes. The smaller poles of *B*, therefore, serve appropriately in accomplishing the desired construction.

Referring to Figs. 8 and 9, Fig. 8 is a view to scale of a 5-h.p. four-pole motor, 700 r.p.m., of the usual type, which may have its speed varied in the neighborhood of 15 per cent or 25 per cent by varying the field flux. Fig. 9 is a view also to scale of a motor of the same horse-power output, the difference being that the magnetic circuit and armature are divided and operated as described. Division *B* is .5 in its relative strength to division *A*, and the armature portions have the same relative surface conductors, essentially the one armature. The speed range is 200 per cent, or in the ratio of 1 to 3. The difference in weight and size, as compared with Fig. 8, lies in the extra amount of metal in the enclosing shell and the armature copper and core due to the slight extension in length on account of the space *C*.

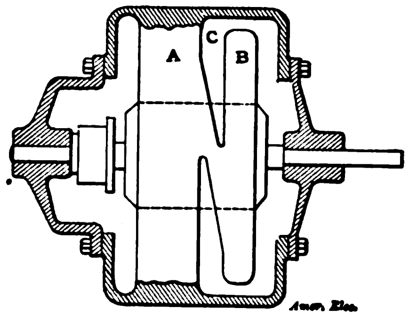

FIG. 9.

Referring to Figs. 10 and 11, Fig. 10 shows a view of a 2½-h.p. motor of 250 r.p.m., having a speed range also of from 15 per cent to 25 per cent by means of field variation. Fig. 11 is a view of the same motor reconstructed to have a speed range of 700 per cent, or a ratio of 1 to 8. The relatively greater size of these motors of small power, compared with those shown in Figs. 8 and 9, is due to the lower initial speed.

The developments and refinements going on in connection with direct-current electric power and generating machinery, chronicled particularly within the past few years, relate in no mean degree to methods of abolishing arcing at the commutator. In many instances a resurrection of old and familiar ideas has been instituted afresh, with a more tangible understanding of the thing itself and its due worth. These methods to a great extent consist of armature magnetism counteracting or balancing coils suitably disposed and determined, requiring no small amount of skill and experimentation. A divided field structure, as described by the foregoing, incorporating an auxiliary magnet-yoke division, through which speed variations are obtained independently of the alteration or variations of the established windings of the main motor division, in the writer's opinion is a more serviceable course to take than to attempt speed modifications through alterations of the primary functions of the motor proper.

ELECTRICAL IRRIGATION.

BY GEORGE E. WALSH.

The extensive irrigation works in operation in the West, or in the process of construction, have given a new appearance to the arid regions, and vast tracts of territory which were formerly of no agricultural value are now producing profitable crops of fruits, grain or vegetables. On the California coast in particular, where the soil and climate are eminently adapted to the growth of grains and fruits, the lack of water was a great drawback, and irrigation has become a feature of the whole industry. The irrigation pumps and machinery employed are of special value because they have been gradually developed to suit existing needs. The early attempts to tap the mountain streams and conduct their waters to the lowlands proved of great commercial value. But in many parts of the Coast this was impossible owing to the great distance between the source of water supply and the farming regions.

Two independent factors have in recent years changed conditions and made it possible to establish large irrigation plants at comparatively little cost. One of these was the discovery that there was sufficient water stored in the underground reservoirs to supply all the fields and farms with the moisture they needed during the dry season. The other was the gradual utilization of the distant mountain streams for electric power generation and the transmission of their power to great distances. Some of the mountain streams furnish power to drive electrical pumps over 100 miles distant, enabling the engineers to utilize the abundant mountain streams in one county to irrigate the fields in another.

In the early part of the present decade the irrigation pumps were driven by windmills and oil engines. The abundant supply of oil found on the Pacific coast seemed to furnish a solution to the problem even without the long-distance electrical transmission. Oil there could be supplied at a cost of 40 or 50 cents a barrel. At this cost for fuel it was possible to make irrigation cheap and successful. Companies were organized on the Pacific coast to drive wells and put up pumping stations. The water was found in the arid regions at depths of 50 to 1000 feet; even the latter depth was not sufficient to discourage the irrigators.

The work of harnessing the streams of the Sierra Madre Mountains made a complete change in the industry. These streams are full at all seasons of the year, and their high falls give ample power in the dry as well as the wet season. They are situated from 50 to 100 miles back from the dry agricultural regions. The original purpose of the pioneers in carrying the electric power from the mountains to the plains below was to supply power to the mills, factories and railways. Los Angeles, 83 miles away, was an excellent market for cheap electric power, and thither the wires were run.

After the power was transmitted successfully the question of finding new customers for it was agitated. Until then no thought had been given to working pumps by electric power; but along the line of the wires a few small pumps were put up. Others quickly followed, and to-day along the line of the long-distance electrical transmission there have sprung up scores and hundreds of irrigating pumps operated by electric motors. There is ample power at all seasons of the year to keep the pumps going, so that dry weather has lost its terror, and farms and fruit orchards have sprung up all along the line.

The electric current, used only when needed, has made irrigation pumping the easiest and cheapest in the world. The farmer needs his power only in emergencies, or during the dry weather; but at such times the need is urgent and imperative. During the rest of the time his pumps are standing idle. The certainty of having power when needed, and in large quantity, is one of the great factors that has made irrigation profitable on the Pacific coast. A single pump such as is used in the Far West irrigates a tract of from 50 to 75 acres, and farms or ranches of any size can easily be supplied.

The driving of the wells in some regions is the most expensive and difficult problem to face. Where the depth is unusual the initial cost of the irrigation outfit is quite serious. On some ranches, however, it has been found perfectly feasible and satisfactory as a money-making investment to sink the wells to the extreme depth of 1000 feet.

Between Los Angeles and the Sierra Madre Mountains, from which the power is drawn, there are upward of 600 electric pumps now in active operation, with scores of others in contemplation. So great is the demand for the power for operating electric irrigation pumps that the engineers have planned greater things for the future. The Kern River, which is some 125 miles from Los Angeles and the great orchard and farming region of the Coast, has been “harnessed.” The power from this river will be distributed over an area of princely value.

Land that had been practically worthless is suddenly brought up to a valuation of nearly $500 per acre, and the proceeds from it pay big interest on the investment at that. The orange and other citrus fruit trees yield abundant crops when grown on irrigated land, while olive orchards and vineyards completely change their appearance and productiveness.

Another field that the projectors of the power development have already invaded is that of pumping oil. California oil fields are in their way almost as important as those of Texas or Pennsylvania. Crude kerosene oil is so abundant on the Pacific coast that it is used as fuel by most of the factories and railroads, and the Oriental line of steamers is also making use of it. The output of the oil is bound to decrease, and the pumping will then become more important. The electric pumps practically reduce the cost and inconvenience, and make even the oil engine pumps less desirable.

The ordinary pumping station for irrigation is simple of construction, and not expensive. Small centrifugal pumps are mostly used for the work, and induction motors are used for driving them. One of the stations supplying a farm of 50 acres or more will require as high as 30 horsepower when in operation, and the pumps will supply from 100 to 22 miner's inches of water. This is sufficient to supply almost any farm or ranch will all the water needed in the dryest of seasons.

The pumps are all housed in wooden buildings, with ditches running to them for conducting the water to the field level. The high tension wires of the electric line are tapped at some convenient place, and carried to the pumping station, where a transformer is used for stepping the voltage down for use by the motor. When the irrigation ditches are filled to suit the needs, the pump is shut down.

The dry season on the California coast extends from May to November, and during this time the pumps are kept in pretty active operation. The fields are never allowed to dry up, for the water is continually flowing over the ground through the ditches and their lateral extensions. Nearly every farm and ranch in this region is practically gridironed by electric wires.

RAWHIDE IN ENGINEERING.

BY E. N. PERCY.

Rawhide has so many excellent qualities and has been successfully put to so many uses that it is to be regretted that engineers are not better informed regarding it. Being much tougher than leather, also more pliable and soft, it is a superior substitute for that article. It can be compressed by hydraulic pressure into a solid mass which has the toughness of iron and is no more brittle than ordinary rawhide. Rawhide will wear longer under certain conditions than any known substance. When wet it is self-lubricating and almost frictionless.

It is very important for rawhide to be properly cured. If it is not, it decays in damp places, swells, gets soft and loses its strength. On the other hand, if properly cured, it makes the finest of hydraulic packing. Braided to size, much the same as flax is, carefully cured and impregnated with grease, it becomes a fine packing. It costs about five times as much as flax and lasts six or eight times as long. As there are no fibres or fabrics to harden, no rubber to wear out, the rawhide need never be removed, merely more forced into the stuffing box. It is in successful use as water packing on pump pistons, stuffing boxes, hydraulic rams, and in many other places. It does not make a good steam packing because it quickly burns out.

Rawhide gears have attracted favorable attention for a great many years. They are noiseless and require no lubrication. Ordinary gear teeth break at the corners, no matter how broad they may be. This is due to the shock of iron to iron and the imperfect line of contact. Rawhide gears cushion this shock and lend themselves to a more perfect line of contact. As they are made of discs or washers bolted together under great pressure, they cannot break; hence are capable of much higher velocities. The blanks are machined the same as metal and take a high finish.

Belts which slip badly can often be cured by covering the band wheel with rawhide finishing, which gives a very clinging surface. Rawhide gears can be used in many places where metal gears are out of the question and where belts were formerly considered the only possible transmission. One of the most common uses of these gears is in connecting electric motors to triplex pumping plants. Prominent manufacturers use gear transmission with rawhide pinions exclusively. A rawhide belt will far outlast a leather belt. It is softer, more clinging, never hardens, and is much stronger. Round belts are made almost exclusively of rawhide, also bell cord, as it twists better, wears less and is stronger. A round leather belt dries and cracks quickly.

No rope is better suited to the engineer than rawhide. It has no slivers, picks up no filings or glass, grease does not hurt it, and as it is more pliable it is good for blocks, slings, whips, etc. Braided rawhide cord makes excellent grips for tools, levers, hot valves, as well as stout whistle and bell ropes. For belt lacings, rawhide is without a peer. It is as soft as buckskin, much stronger, and is not as dry and grainy as leather. A mallet or hammer for finished metal work made of a block of compressed rawhide is superior in every way to a wooden mallet and it never splits or chips. A rawhide cap over an ordinary hammer makes a tool that is noiseless, also harmless to finished work. Blocks of the material make fine bumpers, fenders and other contrivances that have to receive blows. A steel cap over a pile, protected by a rawhide bumper, has been found to wholly prevent splintering of the pile.

In grooved wheels for rope drive, compressed rawhide has been found to make the best known filling for the grooves; it increases traction and diminishes the wear on the ropes due to slipping. One of the most perplexing automobile troubles has been assisted to a solution by this useful material. The weakness of automobile tires, even the best, is proverbial. If even poor tires are equipped with the stout rawhide tire shoes recently placed on the market, they become almost immune from puncture; in fact, puncture is impossible from anything less than a sharp spike. For use on automobiles, rawhide gears have been found more satisfactory than even forged steel gears, and many of the prominent makes are regularly fitted with them. Their noiselessness is no small inducement.

Aprons of rawhide for mechanics and professional men are very satisfactory because of the strength and softness already mentioned, as compared to the board-like stiffness of the leather apron.

AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

Some time ago the writer described a number of standard normal danger signal systems, briefly tracing the manner of developing a system which would give every possible protection for a given section of track. The article being short, it was hardly possible to give enough data from which to draw a conclusion or even deduction as to the relative merits of any given system. It is the purpose of the author in this article to take up and show the relative inherent advantages of each standard system as concisely as possible.

For some unknown reason, the attention of electrical engineers has rarely been openly directed to the important field occupied by the automatic railroad signal. On account of the complication of circuits, especially where a number of miles of protected railroad are connected, they are rendered, if the peculiar conditions to be met with on steam railroads be omitted, as much a field for electrical engineers as the storage battery or the synchronous motor.

While it is the purpose of this article to deal with signals from a purely electrical standpoint, a few facts are given to show the relation of electric signals to modern railroad engineering.

The development and perfection of the automatic signal has been very rapid during the last few years. This development has been rather along the lines of simplicity with reliability of indication rather than perfection in mechanical detail. The standard signal of twelve years ago was very different from the one in use to-day.

In Figs. 1 and 2 are shown two views of a signal of that time. This is operated by a weight in a manner similar to that of an old style clock. The controlling mechanism consisted of an electromagnet which obtained its current from a battery connected to the track of the block which the signal protected. The armature of this magnet was so connected to the moving system that when current was not passing through it, the signal arm was at danger. This signal was intended for both day and night indication.

Fig. 1 is a side elevation of the signal mechanism with the signal indicating safety, and Fig. 2 is an elevation which shows the signal at danger. Referring to the illustrations, a semaphore, *b*, gives indications by day, and is directly connected with the moving system *d*; this latter is operated by a weight, not shown, fastened to the chain *n*.

The magnet *m*, through the interposition of the lever *g* controls the movements of *d*. Moving with *b* through the rod *f* is the spectacle *t* which passes before the circular piece of plain glass *a*. *t* serves to give indications by night, a lamp being situated behind it so that the rays are intercepted by this lens. The weight *i* acts against the signal operating weight in such a manner as to control the signal blade movement.

In the lower part of the illustration is shown the means by which the operating weight *i* when it passes to its lower position, holds the signal at danger by opening the circuit at the contacts *u*. The following, which forms one of the claims in the patent covering this signal, will explain, to the reader, the combination.

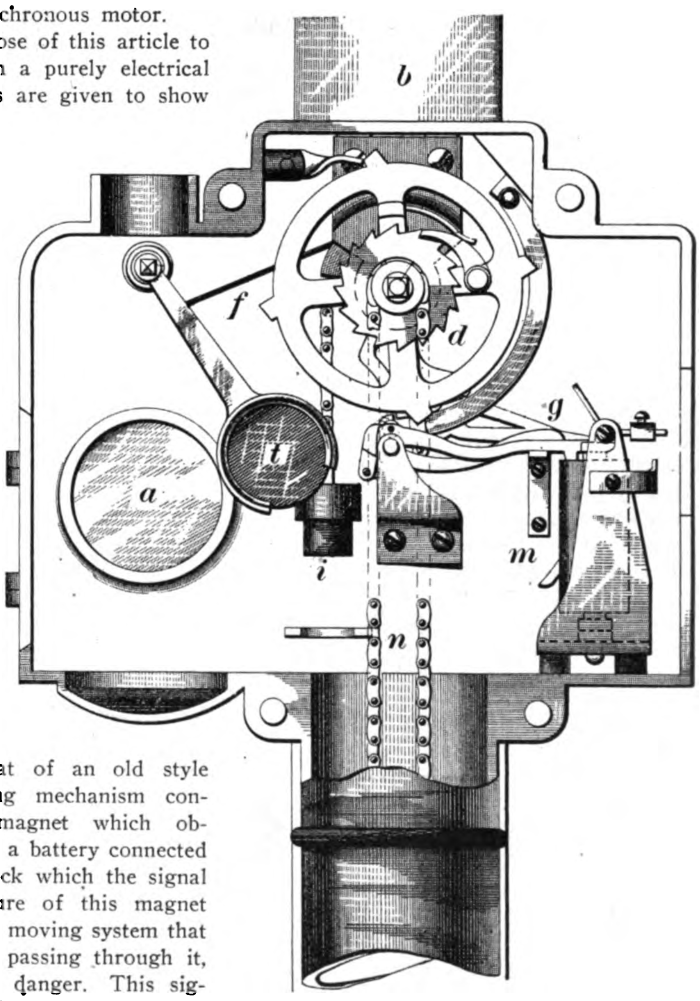

FIG. 1.

"In a semaphore signal, the combination, with a head of two shafts mounted therein, a visual signal blade and a weighted arm secured on one of said shafts, a pivoted latch on one end of said arm, a wheel having projections mounted on the other shafts, means for rotating said shaft and wheel, a curved blade to bear on the pivoted latch, an arm mounted in the bracket, a link connecting the curved blade in the latter arm, a shaft carrying an armature, an electromagnet and an arm on said shaft for holding the trip mechanism, also means for opening the circuit of this magnet when said weight passes to its extreme lower position, thereby setting the signal at danger."

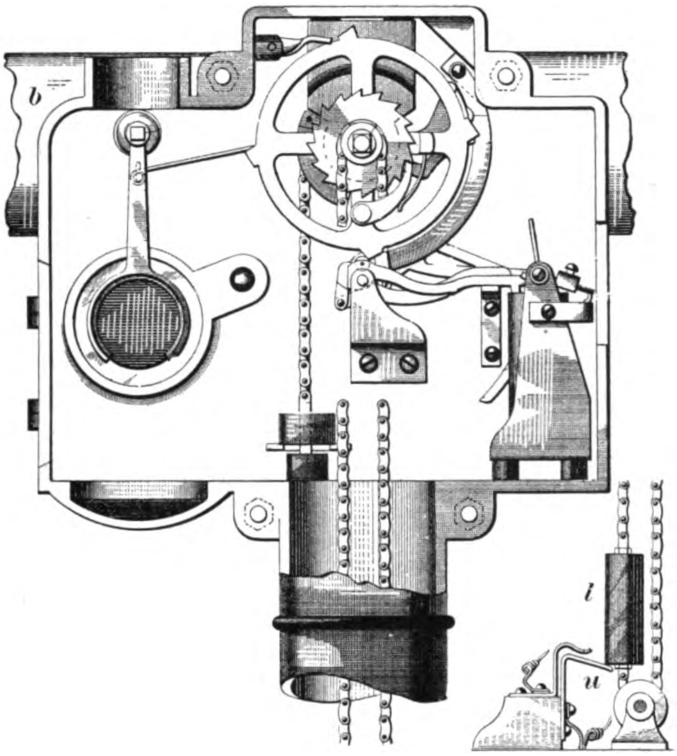

FIG. 2.

The signal used the simple circuit with relay, etc., found in all common signals.

The block signal system is now in use on nearly every American railroad, and in order to show to what extent a representative road is blocked, and the average number of signals per mile, Fig. 3, taken from the *Railroad Gazette* of June 16, 1902, is given. This represents the arrangement of signals on the Philadelphia division of the Pennsylvania Railroad, from Philadelphia to Paoli, a distance of twenty miles. The signals on this section are of the normal clear, electro-pneumatic type.

The electric semaphore signal represents at the present time the highest development in automatic signaling. This is because the semaphore, even at great distances, is much more distinct than any enclosed form of signal. The sleet which in winter covers the glass on the case of the enclosed signal renders a clear view of the banner impossible. This necessitates a stoppage of the train to ascertain the indication, since an obscure signal is always taken as danger.

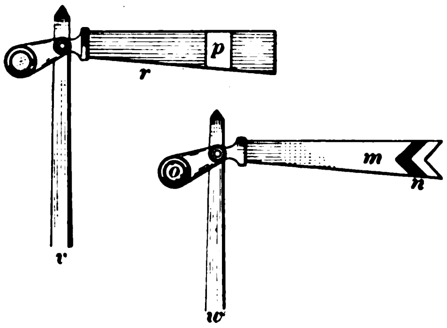

FIG. 4.

The semaphores used are of the same design as those of standard mechanical signals, but means are provided for securing freer motion. The signal arm is moved to the clear position by an electric motor of from 1/8 to 1/6 horsepower, usually located within the base of the signal. The semaphore is generally built to return to the stop position by gravity, the semaphore arm overbalancing the other parts.

The movement of the semaphore is effected in such a positive manner through suitable gearing, that sleet, wind or snow have no effect upon it. The signal, however, is not held in the clear position by the motor, since this would tend to needless waste of energy; but by means of an electro-magnet having high resistance which is permanently connected across the battery terminals as long as it is necessary to hold the signal at clear. Usually these magnets are known as signal slot magnets, and act against gravity by means of a suitable arrangement of levers or cams.

Signal Semaphor Arrangement.

At v and w in Fig. 4 are shown home and distant boards respectively, on separate masts. Each semaphore is used to protect a single block, without reference to the block ahead. This is the practice followed when the blocks are of very great length and are particularly designed for application to single track roads.

The advantage of having home and distant blocks on separate masts is to preclude, as far as possible, the occurrence of the danger condition of a block after the train has passed the home signal. With a very long block such a condition could readily occur. The home semaphore has the form shown at v, the greater part be-

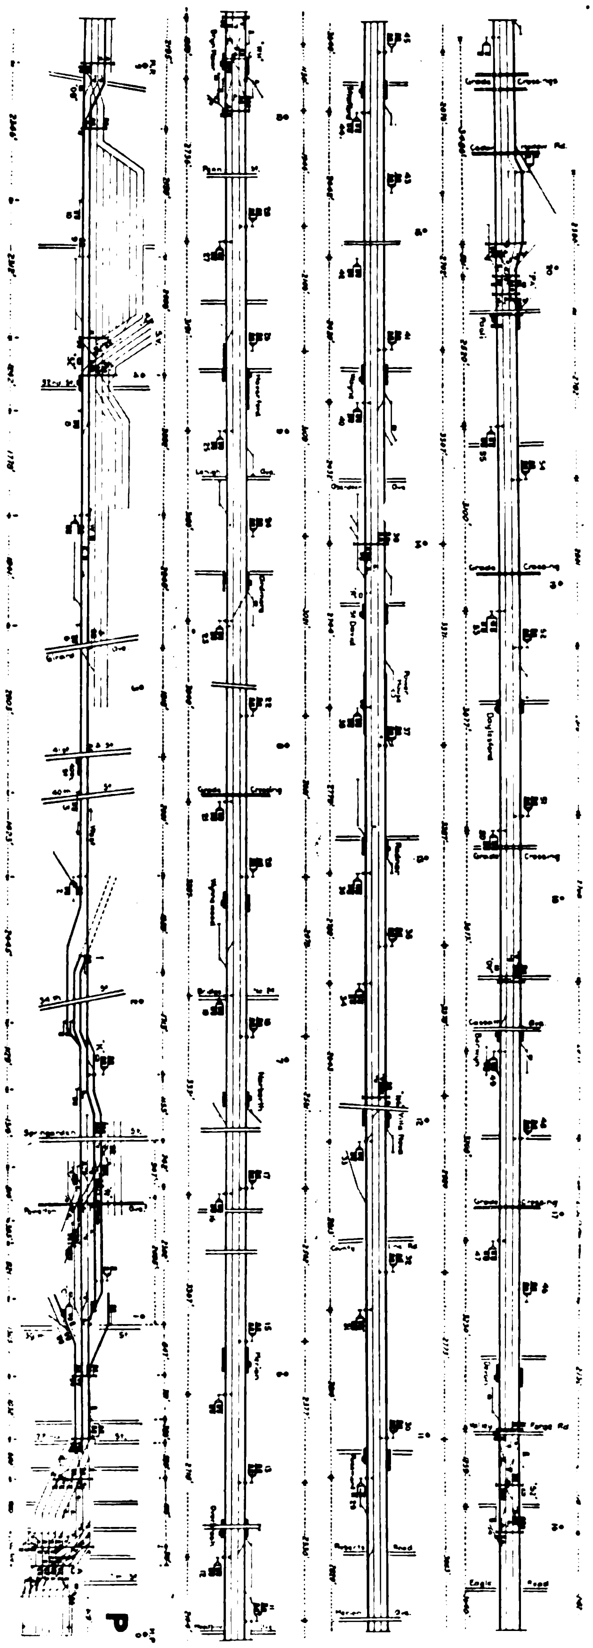

FIG. 3.—BLOCK SIGNAL SYSTEM IN USE ON PHILADELPHIA DIVISION OF THE PENNSYLVANIA RAILROAD.

ing painted red, as shown shaded at *r*, with a small band of white *p*. The distant or fish tail semaphore *w* has a red, yellow or green body *m* with a band of black or white, *n*, parallel with the fish-tailed end.

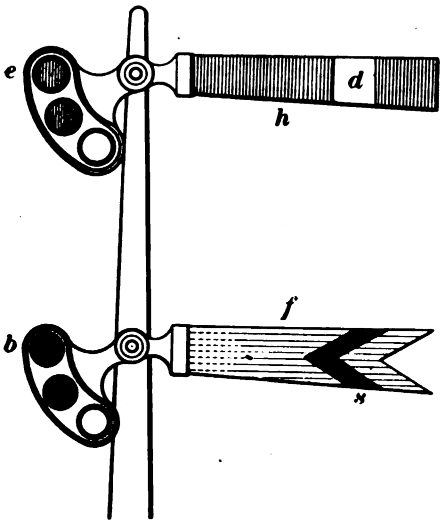

FIG. 5.

The arrangement of a three position signal having home and distant arms on the same masts is shown in Fig. 5, the parts *h*, *d*, *f* and *s* being red, white, yellow and black as in the above. The ends *e* and *b* carry the spectacles, each of these being of a different color, to indicate the relative position of each semaphore. When the arm is 90° from the vertical, danger is indicated, when at 45° caution, and when the position is directly vertical, clear.

This arrangement of indication requires more complicated mechanism than the two positions form, but they are used extensively on a number of trunk lines.

In Fig. 6 three forms of enclosed disc signals, adopted by various roads, are

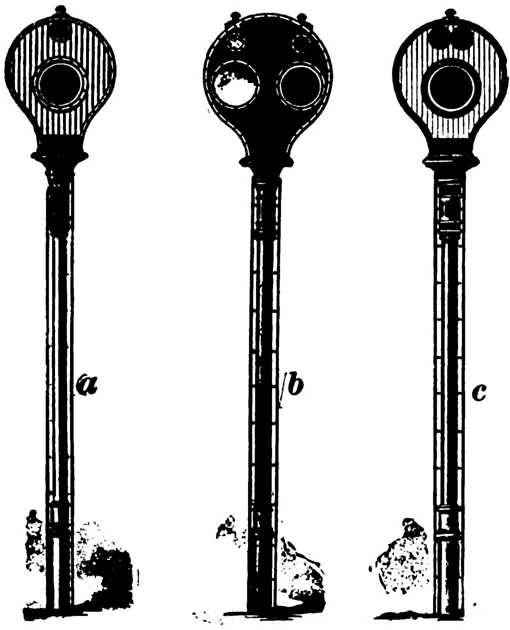

FIG. 6.

shown. *a* is a single block, home and distant signal, *b* a home and distant or two track signal, and *c* a two position signal. Each of these has its special application, but they are not at the present time regarded as standard.

In Fig. 7, a standard semaphore, normal danger, three position motor signal is shown. The batteries are placed within the lower and larger of the cases at the base of the signal mast, the upper case being used for the motor and connections. This signal represents, in form and construction, the result of years of experience in signal development, and it will probably be many years before its outline is radically changed.

Signal Circuits.

In Fig. 8 a simple, normal, clear signal circuit is shown, the two consecutive home signals *H* and *F* having the insulated cut sections 1, 2, 3, 4, 5 and 6. Sections 3, 4 and 5 are in the block protected by *H*, and 1 and 2 in part of the block protected at *F*. Batteries *G* are connected to the farther end of each section, the trains being imagined to move from 6 to 1. The relays *D*, *C*, *A*, *E* and *J* are connected to the opposite end of each section from the respective batteries.

Normally, with no train on either section, the main batteries *R* are discharging current into the signals and, consequently, holding these in the clear position. A train in the block of either section will de-energize one or more of the relays by short circuiting the track batteries, and, by open circuiting the signal battery, hold the signal at danger. The signals in this case are not effected by the movement of a train which approaches either.

In contradistinction to the above, the normal danger signal circuit is shown in Fig 9. As before, two signals are given, these indicating for trains bound in one direction only. Cut sections 7, 8, 9, 10, 11 and 12 are connected respectively to the relays *S*, *V*, *R*, *P* and *Q*. The armatures of the latter are normally held against their contacts, except the lower armature on the relay *R*, which normally breaks the circuit.

The purpose of this latter is to close the circuit of the main signal battery, and, consequently, operate the signal. This will only occur when a train is in a section opposite, and in front of the signal. Hence, when the train is in this section, the signal is moved to the clear position provided all of the other relay armatures in the circuit of the main battery are up, which will not be the case if a train be on either section of the block which the signal protects. Thus, if a train be in section 7 and another train be approaching the second signal, the latter will be held at danger, for the circuit of the signal will be broken at relay *S*.

Hence, a normal danger signal is always at danger, unless a train be approaching it, and then only when everything is in condition to warrant the safe movement after the signal has been passed. In the normal clear system, on the other hand, the signals are always at clear, except when a train is in the block protected by the signal.

A somewhat different and more complicated arrangement of normal danger signal circuits is shown in Fig. 10. This diagram shows the means employed for causing a signal to move to the clear position as soon as the train has reached any part of the block immediately preceding it. Thus, if the lower armatures of either of the relays *M*, *W* and *T* drop, the signal *U* will move to the clear position; that is, if the armatures of the relays *K* and *L* be in the upper position.

This is because the sections 3, 4 and 5 have relays whose lower armatures are connected in multiple, so that if a train be on either section, the signal will move to clear. The same relays have upper armatures, connected in series with the main battery operating the signal *F*. Hence, but a single set of relays is necessary. This diagram, with modifications, represents the usual practice followed in normal danger track circuits on non-polarized line wire systems.

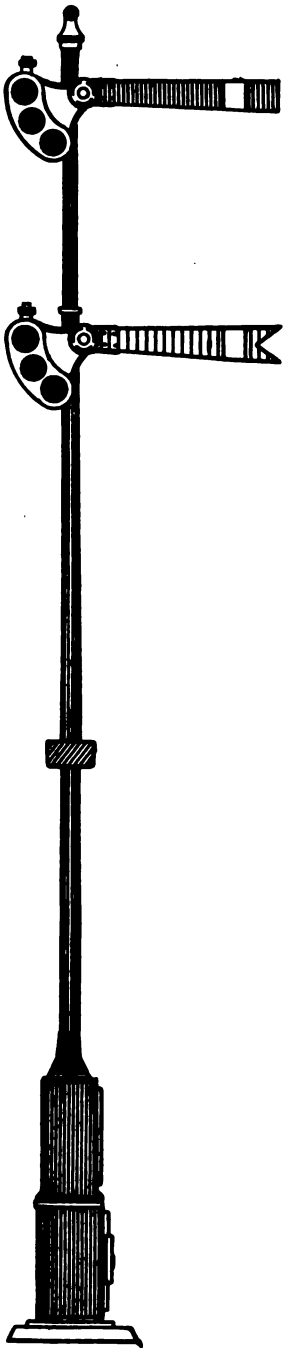

FIG. 7.

The arrangement of the circuits for a home and distant normal clear system on the same masts is shown in Fig. 11. Two signals, *T* and *P*, protecting both home and distant blocks, are operated by means of the relays *O*, *M*, *B*, *W* and *Q*, each having two armatures, the upper of these being connected to the distant, and the lower to the home discs, to the various cut sections.

FIG. 12.

The home disc on *P* is operated by contacts on the armatures of the relays *B*, *W* and *Q*, connected to the sections 3, 4 and 5 and the distant board by the relays *O* and *M* of the sections 1 and 2. Line wires are used in this case to connect the various relays.

The two general means employed for holding a signal at danger when a switch is opened are shown in Fig. 12. Switches are supposed to be located at the sections 8 and 10. A switch instrument at *B* in this case, by the opening of a switch, sets the signal at danger by short circuiting the relay *D*.

This is effected by contacts within the switch instrument which are connected to the tracks by separate wires, and which, through the action of a rotating or moving member, short circuit the track when the switch is opened. The great objection to such a system is the liability of a poor contact or no contact at all to cause a dangerous condition, but not short circuit the relay. Although this condition is of very rare occurrence, it does not represent good signal engineering, as in every signal system, it is not the ***probability*** but the ***absolute certainty*** of the correct action of all apparatus which signifies safety.

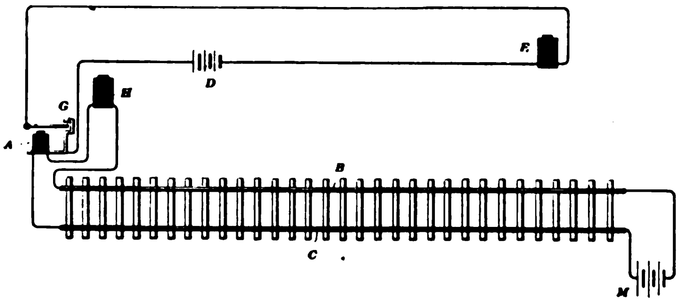

FIG. 13.

At *F* in the illustration another appliance for accomplishing the same purpose in a more reliable manner is shown. The switch instrument at *F* opens the circuit of the signal *N* whenever a switch is opened, even though all the relays *E, G* and *I* be energized.

Although a circuit cannot be closed with any degree of certainty, it may be said that with a low voltage system one can be opened with absolute certainty. The worst that a poor contact can do in this case is to hold the signal at danger. The circuit is closed by means of a roller moving on a spring contact, this roller being moved by the switch through the interposition of suitable connecting means. How this is effected will be shown later.

The normal clear line wire for controlling home and distant boards on separate masts is shown at Fig. 13. The track relay *A* is connected to the rails *B* and *C*, which latter are connected (at the other end of the section) to the batteries *M*. In series with *A* is the magnet *H* which operates the home board.

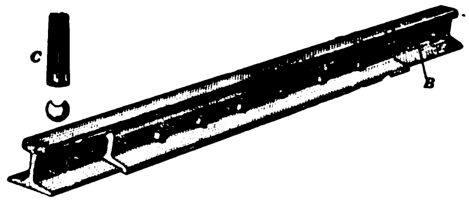

FIG. 14.

When current passes through *H*, as will be the case when the home board is at the clear position, the armature at *A* will make contact with *G*, and thus send current from the battery *D* into the distant magnet *E*. This will not be the case if the line wires are open at any interposed relay. Consequently, when current passes through the home signal magnet the distant signal circuit will also be closed.

It is evident in the track circuits which have been described, that an open circuit in the rails of a section will cause the armature of the relay controlling this section to drop, by depriving this relay of battery current. Hence, on account of the unreliable contact between the fish plates and rails some surer method is necessary to keep the track of each section electrically continuous.

The means for accomplishing this are given in Fig. 14. The bond wire *B* (No. 10 B. W. G. galvanized-iron wire) is connected to the rails, across the fish plates, by channel pins, one of which is shown at *C;* these channel pins being driven with the wire into a hole bored in the web of the rail. The operation of driving home the channel pin makes a contact that can be depended upon.

The bond wire shown is placed beneath the fish plate. This is the usual practice, as it renders the wire inaccessible to mischievous persons. The disadvantage, however, of this method of installation is the fact that the wire is extremely liable to be rusted off, which condition is hard to detect.

The failure of a certain signal thus renders imperative the inspection of all the bond wires in the section where the relay is inoperative. On account of the loss of time incident on such an occurrence, therefore, some railroads place the bond wires outside of the fish plates. In many cases, two wires are used to decrease the factor of the possibility of failure.

BOILER WATER LEVEL INDICATORS.

BY R. T. STROHM.

There are two excellent reasons why the water level in a steam boiler should be readily ascertainable at all times. The first involves the question of safety. There is no fireman who does not feel a greater sense of security in knowing that the upper rows of tubes are well covered, than in suddenly discovering that the only level at which he can draw water from the boiler is at the blow-off. The second reason involves simply the proper working of the boiler. If the water level is maintained at a height greater than that for which the boiler was intended, the steam space will be restricted and priming may occur, especially if the fires are forced.

The water level in a boiler may be determined either by the use of a gauge glass or by the use of try-cocks, while in most cases both fittings are furnished, so that one may corroborate the other. The gauge glass consists of a straight glass tube, connected at one end with the steam space of the boiler and at the other end with the water space. The water then rises to the same level in the glass as in the boiler, and consequently the height of the water is at once apparent to the fireman. Gauge glasses are made with external diameters ranging from ½ in. to 1 in., and from a few inches to 2 ft. in length, depending upon the size and type of boiler to which they are attached. Fig. 1 illustrates a gauge glass as located directly on the shell of the boiler, *A* being the glass, fitted into two angle valves, *B*, B^1, at its ends. These valves are for the purpose of shutting off connection with the boiler in case the glass must be removed, or in case the fires are banked and the boiler allowed to carry steam, under lowered pressure, during the night. The reason for the latter precaution is readily apparent. In many a place where only a day engineer is employed, the fires are banked in the evening so that the plant can be quickly and easily put into operation next morning. If the water glass valves are left open, and the glass should break during the night, the escaping steam may cause much damage to the building and its contents. Actual occurrences of this nature have proven the wisdom of closing the connections to the gauge glass when allowing the boiler to stand idle under steam pressure, in the absence of either engineer or watchman.

The gauge glass is simple and cheap, and furnishes an easy method of determining the level of the water in the boiler. It is open to the objection, however, of being brittle and liable to fracture, either by accidental blows, by sudden chilling due to air or water, by stresses due to expansion and binding in its fittings, or by reason of weakening under the effects of prolonged corrosion. To minimize the breakage by accidental blows, the gauge is protected by rods, *C, C*, parallel to it and at a slight distance from it, held in place by plates attached to the angle valves.

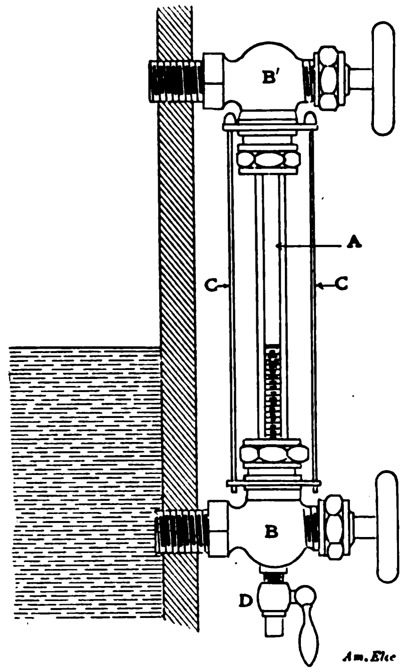

FIG. 1.

The gauge glass most commonly used is that known as the Scotch glass, although there are numerous other makes. These glasses average about three-quarters of an inch in external diameter, and are from one-twelfth to one-seventh of an inch thick. After being drawn and cooled, they must be annealed. For, during the first cooling, the outside chills more quickly than the interior, which sets up internal stresses in the tube. So they are reheated, almost to the melting point, and then allowed to cool very slowly, thus preventing initial stresses.

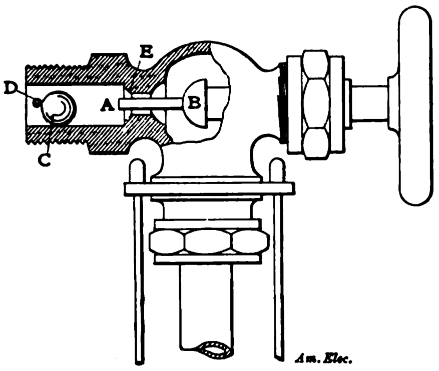

FIG. 2.

Corrosion also effects gauge glasses to a great extent. It not only weakens them, but it frequently discolors the internal surface so as to render it difficult to determine the water level. It is commonly believed that glass is insoluble in water. But in the presence of pure water glass is to a certain degree soluble. The upper end of the glass, in contact with steam, shows this clearly. The steam, condensing, forms drops of distilled water, which is chemically pure, and these drops, trickling down the inner surface of the tube, corrode it. Where soda compounds are used in boilers it has been found that the corrosion proceeds with increased rapidity.

Another objection frequently urged against the gauge glass is that the connections leading to the boiler become clogged with sediment and scale and cause the gauge to give inaccurate and misleading readings. It does not seem quite fair to make an objection of this sort, since any device requires a certain amount of care to maintain it in proper working order, and it is the duty of the fireman to see that the connections are cleaned often enough to prevent inaccurate observations of this nature. It will be noticed that by removing the bonnets of the valves, *B* and B^1, Fig. 1, and taking out the valve stems and discs, straight passages are obtained opposite the nipples leading into the boiler, and so the connections may be easily and quickly cleaned as often as may be necessary. The cock, *D*, is attached for the purpose of blowing out any sediment which may settle in the valve, *B*, as well as for emptying the gauge glass in case it needs to be repacked.

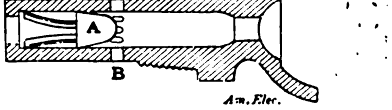

FIG. 3.

In case the gauge glass breaks, and there is no provision for shutting off the escaping steam and water except by closing the valves, *B* and B^1, the fireman has an unpleasant duty before him, and one which promises burns and scalds. To obviate this danger, automatic stop cocks have been invented, one form of which is illustrated by Fig. 2. The figure shows a partial section of the steam end connection of a gauge glass. The stem, *A*, of the valve is continued through the disc, *B*, in the form of a slender rod, which projects through the hole in the valve seat into the nipple leading to the steam space. In this nipple is a metal ball, *C*, somewhat smaller in diameter, which is kept from rolling out into the boiler by means of a pin, *D*. So long as the gauge glass is intact, the ball, *C*, lies against the pin, *D*, the valve stem extension, *A*, being withdrawn out of the opening in the valve seat. Should the gauge glass break, the rush of steam through the nipple will carry the metal ball with it, lodging it against the seat, *E*, where it will be held by the pressure of the steam, thus preventing any further escape of steam from that end of the gauge glass. A similar device at the lower end is used to shut off the water, in case the glass is broken. After the glass has been replaced the valve stem is screwed in, and the rod, *A*, pushes the ball, *C*, back into position against the pin, *D*. In another form of automatic stop, the ball is replaced by a plug of the shape shown at *A*, in Fig. 3, having springs attached to it to keep it in place. The nipple also is lengthened, and the steam or water admitted through the holes, *B*, *B*. The plug is seated by the rush of steam or water which follows the breaking of a glass, and is forced back into place by an extension of the valve stem, as illustrated in Fig. 2.

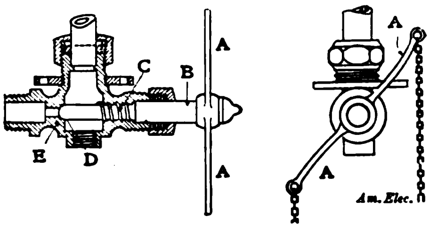

FIG. 4.

A non-automatic device for closing communication with the boiler when the gauge glass breaks is illustrated in Fig. 4. It is simply a quick-closing cock or valve operated from the floor of the boiler room by means of a chain attached to the lever, *A*. The valve stem, *B*, is fitted with a multiple threaded screw, *C*, of large pitch, so that the rotation of the lever, *A*, through about half a turn is sufficient to move the end, *D*, of the stem against the seat, *E*, and close the valve.

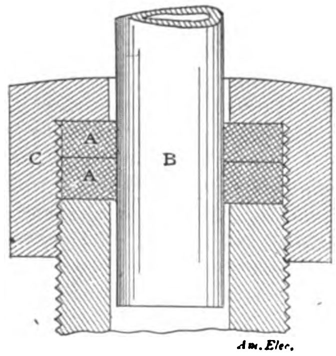

FIG. 5.

In several forms of water-tube boilers in which the water gauge is attached directly to the head of the steam drum, and in vertical boilers, the gauge glass is at a considerable distance from the floor of the boiler room, and it may become difficult to detect the water level if the glass is discolored, or if the lighting of the room is poor. To render the water line easy of determination, glasses are made which show different colors in the water and steam ends of the gauge. In one type, the water shows red, all the steam space showing plain, making it a simple matter to locate the water level. In another, the portion of the glass filled with steam appears silvery white, while the portion filled with water appears black, making the point of division very apparent.

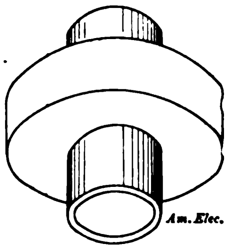

FIG. 6.

The breakage of gauge glasses is very frequently due to binding in the packing at either end. As ordinarily done, the glass is packed as shown by Fig. 5. Two rubber washers, *A*, *A*, are slipped over the end of the glass, *B*, and are compressed by the gland, *C*, so as to form a tight joint. For high pressures, the packing rings must be fairly tight and firm, and they then allow little chance for expansion, while at the same time initial stresses may be set up in the glass itself by screwing down the gland, especially if it is not centered accurately. Accordingly, some engineers have succeeded in obviating this by using a single packing ring, circular in cross-section, in place of the double flat ring shown in the figure. This gives less bearing surface on the glass and permits motion in any direction. Another form of washer which is said to give

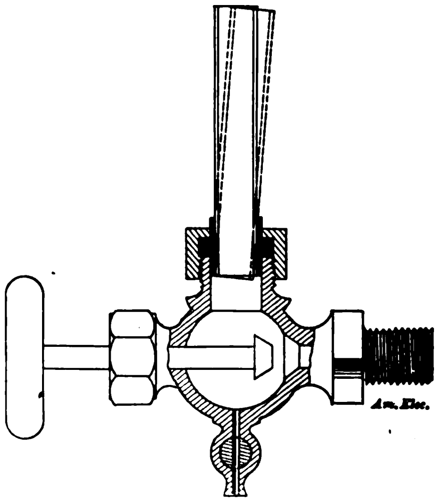

FIG. 7.

excellent results, both in preventing leakage and in preserving the glass from breakage, is illustrated by Fig. 6. The washer is made of rubber and is applied as shown by Fig. 7, forming a flexible joint, yet being perfectly tight by reason of the large surface in contact with the tube.

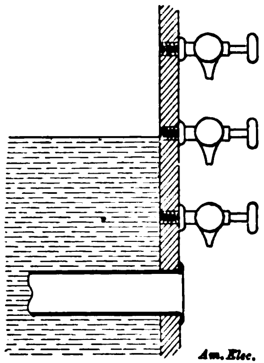

FIG. 8.

While valves between the gauge glass and boiler are advantageous in cases of breakage of the glass, they are regarded as elements of danger by many, as they may be closed, either by responsible or irresponsible persons, and thus give false readings. For example, if the valve, B^1, in Fig. 1 were closed, with the boiler under steam, the steam remaining in the upper end of the glass would some condense, and the water level would rise to the top of the glass, or beyond. If the valve, *B*, were closed, the steam condensing in the steam space of the gauge glass would gradually raise the height of the column.

Consequently, since the gauge glass may, by a variety of causes, give erroneous indications of the water level, it is common to use gauge cocks also, by which to confirm the reading of the glass, or prove its inaccuracy. These gauge cocks are three in number, usually, and are placed one above the other, as illustrated by Fig. 8. The lower one is so located that it is at a distance of about three inches from the top of the upper row of tubes, in boilers of the horizontal tubular class. This distance will vary slightly according to the size of the boiler. The lower gauge cock is thus at the lowest desirable level which the water should attain in actual work. The upper cock is placed at the highest desirable level at which water may be carried, so that the middle cock is at the normal water level. The height of the water may then be easily determined by opening the three gauge cocks in succession. If steam issues when the upper and middle cocks are opened, and water issues upon opening the lower one, it is evident that the water level is somewhere between the middle and the lower cock. The latter is so placed that its center line is at a slightly higher level than the lowest visible point of the gauge glass. Consequently, if there is no sign of water in the glass, and steam alone issues from the lowest gauge cock when it is opened, the water level is dangerously low.

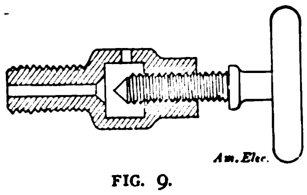

FIG. 9.

One of the most common forms of gauge cock is that shown by Fig. 9. It is simply a body containing a beveled seat into which is screwed a conical plug formed at the end of the stem. The construction is cheap, and the great objection is that the plug always seats in the same position, so that the cock leaks after short service. Repeated grinding, while serving to lengthen the usefulness, eventually destroys the cock entirely. To provide a gauge cock which would be cheap and permit of inexpensive repairs, the type illustrated by Fig. 10 was devised. Instead of a beveled seat, it is made flat. The end of the screw plug is recessed and is filled with babbitt metal. As soon as this babbitt becomes so crushed and worn as to cause a leak, the plug is removed and rebabbitted, thus making the cock as good as new. The seat, being much harder than the metal in the plug, will wear little if any, and it can be faced off whenever necessary, without difficulty.

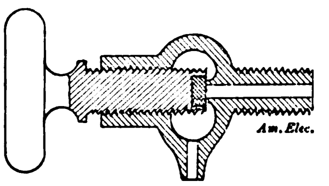

FIG. 10.

The two gauge cocks previously described are slow of action, since they necessitate screwing a stem out and in. A form of quick-opening cock is shown in section by Fig. 11. The body is made hollow, with a beveled seat at the inner end into which fits a disc forming the end of the stem. This stem is somewhat smaller than the hole in the body of the plug and has a sliding fit in the outer end of the plug. The steam or water pressure, acting upon the end of the stem, tends to hold the disc tightly to its seat and prevents leakage when the boiler is under steam. To open the cock the button, *A*, is pressed inward, forcing the disc, *E*, from its seat, allowing steam or water to enter the annular passage, *C*, from which it flows into chamber, *D*, and out at the discharge, *E*. As soon as pressure is removed from *A*, the steam pressure within forces the disc to its seat. This cock, however, is open to the same objection as the two previous ones, since it is liable to close in the same position every time, and eventually leak badly. On the other hand, it may easily be reground.

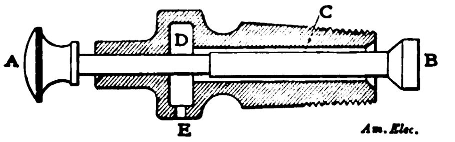

FIG. 11.

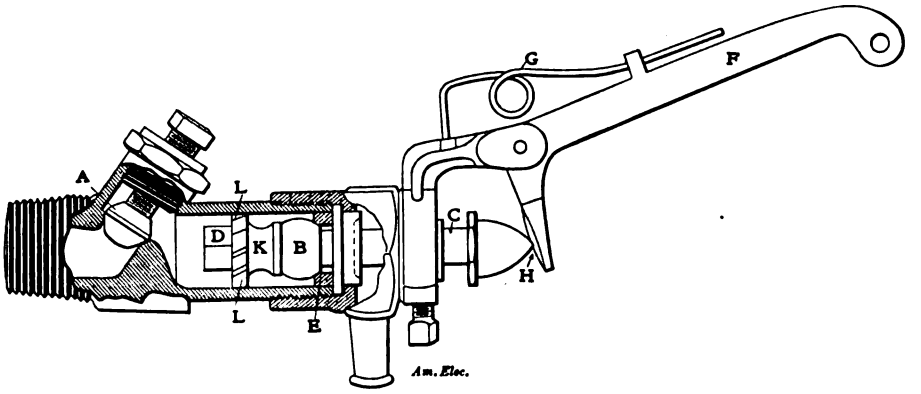

FIG. 13.

A quick-opening diaphragm gauge cock is illustrated by Fig. 12. The cock has a flat seat over which fits a disc, *A*, attached to the diaphragm, *B*. The disc is recessed and filled with rubber or some soft composition metal which will wear much more rapidly than the seat and can be cheaply replaced. The diaphragm is held in place by screwing up the bonnet, *C*, tightly. This bonnet carries a movable stem, *D*, whose head, *E*, presses against the disc, *A*, and keeps the cock closed. The pressure of the stem is due to the helical spring, *F*, which is compressed by the nut, *G*. The cock is opened by pulling downward on a chain or cord attached to the lever, *H*, this motion serving to take the pressure of the spring from the diaphragm. The steam pressure from within will then lift *A* from its seat. The purpose of the diaphragm is to prevent the contact of live steam with the spring, *F*, which might destroy its elasticity. This spring may be set at any desired tension, by adjustment of the nut, *G*, to accommodate it to various boiler pressures.

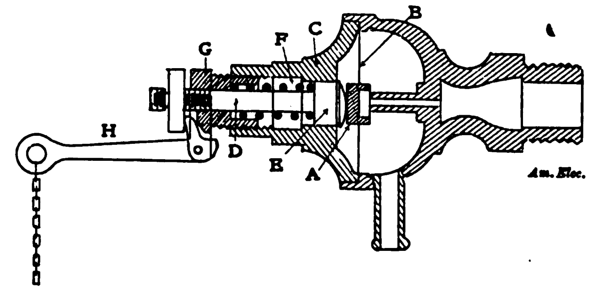

FIG. 12.

The gauge cock shown in Fig. 13 has a number of distinct advantages. In the first place, it is provided with an outside shut-off valve, *A*. In all the other forms it is necessary to remove all pressure from the boiler in order to take out the discs or seats for repair. Or, if this is inconvenient, they must be allowed to leak until the boiler is put out of commission for cleaning or repairs. When the cock in Fig. 13 needs regrinding, the boiler pressure is shut off by closing the valve, *A*. The parts may thus be removed and repaired while the boiler is under steam pressure. The valve, *B*, consists of a bell metal ball held to the stem, *C*, by a nut, *D*. This ball has two faces which are alike, so that if one becomes worn the other may be turned toward the valve seat by simply reversing the position of the ball on the stem. The valve fits close against a seat, *E*, of phosphor bronze. The seat is also made double-ended, and is reversible. Thus the two wearing parts, the valve and the seat, are both able to outlast the ordinary types by reason of their two faces. When in use, the valve, *A*, is opened fully, and the ball, *B*, is held to its seat by the steam pressure. The cock is opened by a downward pull on the lever, *F*, which is returned to its original position by the spring, *G*. The end of the stem is drawn to a point, as at *H*, so that the stem may rotate without being resisted to any great extent by friction against the short arm of the lever. Inside the cock, the stem is fitted with a circular attachment, *K*, on which are vanes, *L*, *L*. The purpose of this is evident. As the steam and water rush out, upon opening the cock, they impinge against the vanes, *L*, *L*, and thus cause the stem to rotate on its axis. This rotation is intended to prevent the seating of the valve in the same relative position after each opening. The wear is thus more evenly distributed and the life of the gauge cock prolonged.

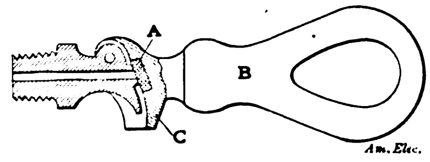

FIG. 14.

Fig. 14 shows a form of try-cock which is to be found on locomotive and portable engines in large numbers. The opening in the valve body is closed by the hard rubber cushion, *A*, set into the handle, *B*, of the cock. This handle is of sufficient weight to keep the valve closed against the pressure in the boiler. The escaping steam and hot water are directed downward by the curved lip, *C*, thus protecting the fireman. This gauge cock is quick-acting, simple, cheap and easy to repair.

Dangers of Using Kerosene in Boiler Cleaning.—When kerosene or any other innflammable substance has been used in a boiler in any quantity, care should always be taken after opening the boiler up to ventilate it thoroughly before bringing an open light near the manhole.

TELEPHONE ENGINEERING.

Cost of Aerial Cable Lines.

BY F. J. DOMMERQUE.

The cost of aerial cable lines is frequently expressed in dollars per mile. The mile unit is by far too great, as in practice a mile of uniform cable line is hardly ever found. Sometimes the size of the cable changes several times in a mile of pole line; sometimes there is open wire construction on the same line; now and then a cable box is inserted, and so on. To form a reasonably correct idea of the cost of aerial cable lines requires an account of all these variations that may occur. The following suggestions will assist in estimating.

The cost of some of the material, such as cables, messengers, hangers, etc., has already been mentioned. In the following the cost of the cable boxes and balconies will be given and then the cost of labor for stringing the messenger, hanging the cable and other items involved in the construction of aerial cable lines. The cost of the pole line itself, that is, the cost of setting the poles and stringing any open wires if such appear simultaneously upon the same pole line, will be discussed elsewhere, also the cost of anchoring and guying. Pole boxes cost as follows:

Boxes fitted for lightning arresters and tubular fuses:

13-pair cable, not including carbon blocks and fuses, about	$11.00
25-pair cable, not including carbon blocks and fuses, about	16.00
50-pair cable, not including carbon blocks and fuses, about	26.00
100-pair cable, not including carbon blocks and fuses, about	46.00

The carbon blocks and mica arresters cost 3 cents per pair and the tubular fuses 7 cents each.

Boxes fitted with arrester springs only:

13-pair cable, about	$10.00
25-pair cable, about	13.00
50-pair cable, about	22.00
100-pair cable, about	40.00

Boxes fitted for fuses only:

13-pair cable, about	$10.50
25-pair cable, about	14.00
50-pair cable, about	22.50
100-pair cable, about	39.00

Boxes fitted with binding post terminals only:

13-pair cable, about	$8.50
25-pair cable, about	11.00
50-pair cable, about	18.75
100-pair cable, about	33.00

The above prices include a cable end connected up, ready to splice to the main cable.

The cost of iron terminals is about the same as the cost of wooden terminals, except for the very small sizes, the so-called "cans," which are somewhat cheaper. Cans with 10-pair terminals, as used frequently in cable construction in residence districts where party lines are numerous, can be had for as low as $4. Of course, a considerable discount from the above prices may be obtained on large lots.

Pole platforms with galvanized-iron railing and braces cost from $15 to $18, according to size. Pole seats with galvanized back support and braces cost about $5; galvanized-iron pole ring with brace, about $4.50. To put up a box and balcony and connect same will cost about 50 cents per line for labor; this does not include the cost of the wire.

Figuring on the messenger and cable required, an allowance must be made for sag, ends that have to be cut off, splices, potheads, etc. The amount to be added to the messenger should somewhat exceed the amount to be added to the cable, as the messenger has to be wrapped several times around the end poles. Three per cent added to the cable and four per cent to the messenger measurements, taken from the distance between poles, should be sufficient.

The labor involved in stringing the messenger varies according to its size. To string No. 4 steel wire costs about 0.8 cent per foot; to string stranded 5/16-in. messenger costs about 1 cent per foot; to string stranded ⅜-in. messenger costs about 1¼ cents per foot; and to string ½-in. messenger costs about 1⅓ cents per foot. This is for the actual labor spent on the messenger. The actual labor of hanging the cable amounts to about ¾ cent per foot for 10-pair No. 19 B. & S. cable, about 1¼ cents per foot for 25-pair No. 19 B. & S. cable, about 1⅛ cents for 25-pair No. 20 and 50-pair No. 22 B. & S. cable, about ¾ cent per foot for 25-pair No. 22 B. & S. cable, and about 1½ cents per foot for 50-pair Nos. 19 and 20 B. & S. cable.

The above figures do not include the cost of teaming, supervision, watch service, inspection, return of empty reels and incidentals. The amount to be charged to this account is from 50 to 100 per cent. of the cost of the actual or straight labor, according to the distance of hauling, conditions of the road, etc.

The messenger has rarely to be spliced, and when a splice is to be made it does not cost much. The two ends to be spliced are formed into loops, one loop passing through the other, each loop being formed by turning the messenger end back upon itself and clamping it by a strand clamp; the cost, therefore, of an occasional messenger splice may be considered taken care of by the cost of stringing. Not so, however, with cable splices, which occur frequently and are costly. The cost, of course, depends upon the length of the different sections and also upon the location of the splice, whether it is difficult to reach or not. Sometimes a splice has to be made over, because in testing faults in connections or pin holes in the joint are often discovered.

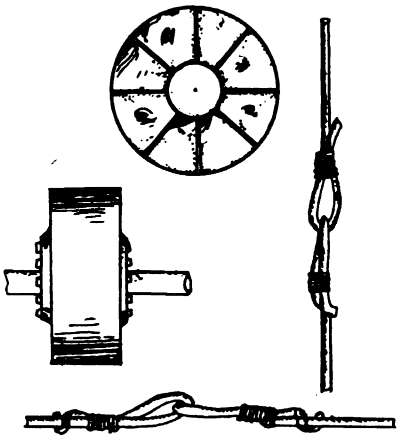
At this juncture attention may be called to a wrinkle in the trade, so to speak. As there are very few splices that do not have to be opened sometime or other, experienced cable men prefer to use for the first making of the splice a sleeve as short as possible and having a rather large diameter, so as to get a short first splice; when the splice is made over a second time they may save cutting in a new piece of cable by using a longer sleeve.

As an approximate figure for the cost of splicing, including also the branch splices to cable boxes, 0.1 cent per foot of 10-pair cable, 0.15 cent per foot of 25-pair cable, and 0.25 cent per foot of 50-pair cable will be about right for average work.

SOME MATERIALS USED BY ELECTRICIANS IN THE PHILIPPINES.

BY OUR MANILA CORRESPONDENT.

Fig. 1 is a drawing of the sort of wood polishing and smoothing wheels that are used by the native helpers of the electrical corps men of the United States Army in the Philippine Islands. The hardwoods of the booaboey tree are used for this work. Sections are shaped with crude tools and the parts are dovetailed together, producing quite a secure wheel. An edge view is shown in Fig. 2. The sides of the wheels are flanged as shown and these flanges are set-screwed to the shaft on which the wheel is turned. The shaft is turned by means of crank and treadle or by hand-crank device. Fig. 3 illustrates the kind of wiring the natives do if not watched. It is necessary for the American linemen to have native helpers, and these fellows make very odd joints. The unions may hold well enough for a time at least, but the style of connection is not always of a workmanlike order. Ofter the Filipino helper will wrap the ends of the wire over and then bind each as shown with cordage or with finer wire, as shown in Fig. 4; the wrapped ends are further aided in keeping the proper grip by twisting once or twice about the wire.



FIGS. 1, 2, 3 AND 4.

The electrical wire people here usually mark all their packages for transportation by escort wagon or pack train with proper letters. Fig. 5 is a sketching of the sort of stencil used for the purpose. The electrician uses sheet metal, usually brass, and cuts the letter out with a cold chisel. The entire alphabet is made, so that any word can be imprinted upon the packages containing the supplies for the corps.

I should call attention to the odd style of combination bamboo poles which one is obliged to use in this country in certain localities where other stock is not available. Fig. 6 is a drawing of one of these combination poles, consisting of a dozen or two of the slender, elastic bamboo pieces, combined as shown and bound up with wrappings of cord and sometimes wire. This style of pole will stand a great deal of typhoon and earthquake shaking without fracturing. The poles are often bent over by the high winds, but seldom break. They are difficult for the American wiremen to ascend, but are easy for the barefooted, agile native wireman. Cross-arms for poles are often constructed in this service on the rather crude yet effective and practical style shown in Fig. 7. The cross piece is usually cut through and the pole inserted as shown. Seldom are nails or screws used; sometimes wooden pins are driven in to secure the parts. Fig. 8 is a design of native hammer often observed in the belt of the native wireman. The hammer head is shaped from stone or metal and bound to the handle of hardwood with wrappings of split vegetation, thoroughly dried and exceedingly tough. Fig. 9 is one of the inverted cone-shaped stone vessels used in the work. These stone vessels are weighty, but they are lasting and serve many useful purposes.

Gasoline Motor Car Design.

To the Editor American Electrician:

Sir:—I have read with considerable interest the article by Mr. Brocksmith in the July number of the American Electrician and would like to inquire whether or not the car, and especially the engine, was ever built as shown.

I am sure that an indicator card or two from the engine would be extremely interesting to the readers of the American Electrician. There are many automobiles in use to-day with four-cycle, air-cooled engines, but a two-cycle, air-cooled gasoline motor is somewhat of a novelty. While the explosion temperature is lower in the latter type, the average cylinder temperature is usually higher, and it would seem that a long hill in the sun, with the thermometer at 90 degrees, would prove an unsurmountable obstacle to the machine described. Another point not mentioned in the article is the amount of speed regulation possible by means of the throttle. Modern machines can be reduced to one-third of the normal speed by throttle control alone, although of course the output is not maintained.

As the drawing shows chain oilers, it would appear that the engine is lubricated throughout by the crank case oil, but if the oil level is carried at the usual point would not considerable find its way through the transfer passage and be carbonized in the cylinder?

The exhaust port is in the form of a slit, giving a full opening almost instantly, which would tend to make a noisy engine. If the port opened more gradually the burned gases would be discharged with less violence and the area of the indicator card would not be materially reduced.

Information as to the quantity of gasoline consumed per horse-power-hour, under working conditions, would be very acceptable, as the mixture burning capacity figures out seven horse instead of six.

There are several points about the car itself to which attention might be drawn. For instance, the transmission is of the sliding-gear type, the chief advantage of which is a direct drive on the highest speed. In the arrangement shown, however, this is sacrificed, the drive being through a spur gear entailing a loss of ten to fifteen per cent. A transmission not involving this objectionable feature would be equally within the ability of any amateur who could build the engine. The use of gears with 1¼-inch face is highly commendable; one of the least mechanical features at the Automobile Show last winter was the 25-h.p. and 30-h.p. touring cars with transmission gears of ⅞ and 1-inch face. The use of reaches and cross springs has been abandoned by experienced builders.

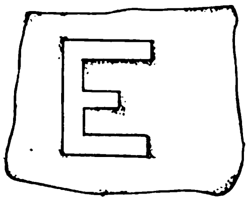

FIG. 5.

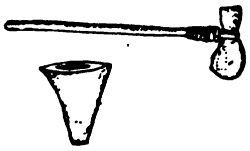

FIGS. 8 AND 9.

The clutch shown is very ingenious, but in view of the fact that both male and female members are entirely enclosed, it would seem better to allow the clutch to run in oil and eliminate the leather facing, as the great objection to this form of clutch is its non-slipping quality, always starting the car with more or less of a jerk. The modifications mentioned would allow slipping for several minutes without overheating.

With the arrangement of clutch and brake levers as indicated, the sensation of a rider, if alone, in case his engine stopped while going up hill, may be better imagined than described, although he might carry a large stone along to drop on the brake lever in case such a contingency arose.

The same comment applies to the clutch lever, as it would be impossible to start the engine unless it was depressed. It is quite evident that these levers should be provided with ratchets, and it would be decidedly better if they were interlocked, so that the clutch would be released when the brake lever was depressed.

These remarks are not made in a fault-finding spirit, but I believe if Mr. Brocksmith ever built the car described, an article on its practical operation would be just as interesting as the article on its construction.

New York, July 9. W. F. Hendry.

Replying to Mr. W. F. Hendry's letter I would say that both the engine and the car are entirely original in design; nothing like them has ever been constructed so far as I am aware. It is quite possible, as Mr. Hendry suggests, that the builder of the machine would find some points which required modification; this is true of any new design.

I see no reason why air cooling is not practicable for a two-cycle engine, but if any difficulty were experienced it would be a comparatively easy matter to fit a fan driven from the engine shaft to assist in cooling the cylinders. As to controlling the speed by means of the throttle, two-cycle engines can be very readily controlled in this way, and in fact every marine engine is controlled by throttle.

In regard to oil being thrown into the transfer ports and carbonized in the cylinder, it is possible that this would occur, in which case it would be necessary to put in splash plates similar to the one shown in my gasoline engine design in the January, 1904, number of the American Electrician. This is a small matter and could easily be remedied if any trouble should be experienced.

It is true that in a two-cycle engine the exhaust escapes all at once, and practically the same thing occurs in a four-cycle engine. The muffler is intended to take care of this violent discharge of the burnt gases, and there is no reason why with a good muffler this engine should produce any more exhaust noise than any other engine. On the other hand, there is the absence of cams, gears, valves, etc., which would certainly conduce to quiet running.

I have no figures on the gasoline consumption per horse-power of this or similar engines, but it is probably somewhat greater than it would be in a four-cycle engine on account of the loss of part of the incoming charge with outgoing exhaust. One should be willing, however, to make some sacrifice in economy in order to secure freedom from the complication and noise of four-cycle engines. According to a formula which I have, the horse-power comes out 8 instead of 6; in this connection it may be said that most formulas for computing the developed power of a gasoline engine are merely approximate, as most of them take no account of the compression, condition of mixture, spark advance, etc., all of which have a decided bearing on the output.

The chief advantage of the sliding gear transmission is not that it gives a direct drive on the high speed; this is only obtained in the latest transmission by means of added complication. The advantage lies in the fact that the sliding forms the simplest and most reliable means of obtaining a number of different ratios of transmission within a limited space and weight. The direct drive is impracticable in the present case because the driving shaft must revolve faster than the motor shaft on the high speed in order to keep the size of the low-speed gears within reasonable limits, and also because it would involve extra complication.

The use of reaches and cross spring is still retained on some reputable motor cars, among which may be mentioned the Packard and Crest cars. It is a question whether or not reaches would be actually necessary in the present design, but if they should not be, it would be a most simple matter to omit them without altering the design in the least.

With regard to the clutch and brake pedals it may be said that the brake pedal would probably be improved by the addition of a locking device or ratchet, but this would depend entirely on the locality in which the car was operated.

If it were to be used in Chicago and vicinity it would answer very well just as it stands; whereas if it were to be used in and around Pittsburg, it would probably have to have a ratchet and also two or three extra brakes for use in emergency.

The clutch pedal is never provided with a ratchet and does not require it. If your correspondent will study the drawing of the transmission gear a little more closely he will discover that there is a neutral position of the lever in which there are no gears engaged, this condition occurring between the first forward speed and the reverse. The motor is started with the lever in the neutral position and the clutch pedal must be depressed when it is desired to engage the first speed.

I believe the design on the whole is quite practical and would not hesitate to construct such a car if I had the time and means to do so.

Chicago, July 16. J. C. Brocksmith.

Abstracts from Foreign Contemporaries

Automatic Protective Devices for Electrical Circuits.—The London *Electrician* publishes an account of some interesting demonstrations of various ingenious devices for the protection of electrical circuits given by Mr. L. Andrews. In the closed magnetic device shown by Fig. 1, the series and the shunt windings are so connected up that under normal conditions the fluxes will flow through the field-magnet limbs in series, avoiding the center path through the movable core and air gap. Should the series current become reversed relatively to the shunt current, the fluxes will oppose each other and traverse the center path, corresponding to the armature of a Manchester dynamo, producing a strong field across the air gap and lifting the movable core with considerable force, thus directly releasing the circuit-breaker without the intervention of a relay. One difficulty, however, with a device of this kind, when used with alternating current, is that a further reduction of the shunt current takes place, owing to the inductive action of the series winding in the cut-out device upon the shunt winding. The device illustrated in Fig. 2 appears to overcome this difficulty. It will be seen that the device consists of a transformer wound with two primary and two secondary windings. One of the primaries, usually consisting of one turn, is connected in series with the circuit to be controlled. A current in this winding tends to produce a flux in the center core of the transformer which divides equally between the two magnetic return circuits and cuts the two secondary windings equally. As a consequence the coils of the relay will both be equally energized, and the coil will neither be pulled up nor down. The potential primary winding tends to produce a flux which flows round the outer magnetic circuit, avoiding the center path. This flux will also tend to cut the two secondaries equally. If now the combined effect of the flux, due to the two primaries, is considered, it will be seen that the fluxes in the upper half of the transformer oppose each other, whereas those in the lower half assist each other; as a consequence the core is forcibly held down. These conditions will be maintained so long as the generator supplies current to the bus bars. Should

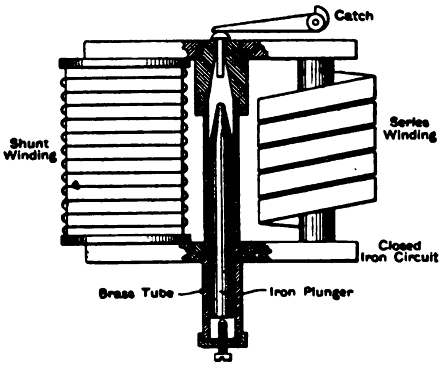

FIG. 1.—CLOSED IRON CIRCUIT RELEASE.

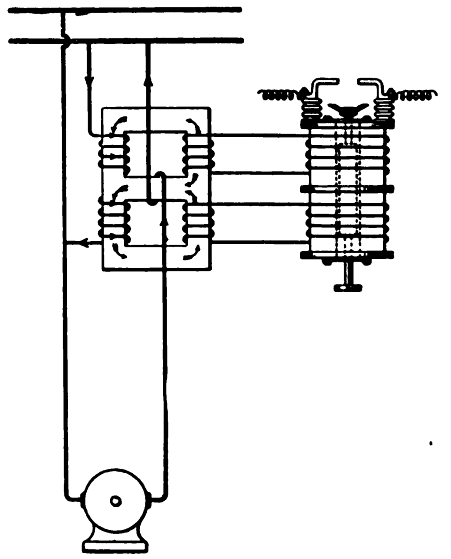

FIG. 2.—DISCRIMINATING RELAY FOR ALTERNATING-CURRENT CUT-OUT.

the direction of the series current become reversed, relatively to the shunt, the fluxes in the lower half of the transformer will oppose each other, and those in the upper half will assist each other, with the result that a much heavier current is induced in the upper secondary than in the lower secondary, and the core is pulled up until it closes the local circuit and operates the cut-out. A method of automatically operating circuit-breakers is shown in Fig. 3. This is an adaptation of a pendulum device *B C D* having a swinging pendulum polarized by a fine wire solenoid, and the free ends of this swinging armature acted upon by two heavy coils carrying the series current. The series winding, *C D*, is in this case connected between the two feeders; as, however, there is normally no difference of potential between these feeders, there will be no tendency for current to flow from one to the other. Should one of the feeders break down, current will flow from the healthy feeder through the series coils of the relay to the faulty feeder, and as this current will have a sense of direction relatively to the shunt winding, *B*, the relay will close the local circuit at *F* or *G*, controlling the circuit breaker, *H J*, on the sub-station end of the faulty feeder. The cross connections shown on the diagram are provided to maintain the choking coil, *A*, non-inductive when one of the feeders has been cut off and the supply continued through the remaining feeder only. A magnetic circuit-breaker with a time element device is shown in Fig. 4.

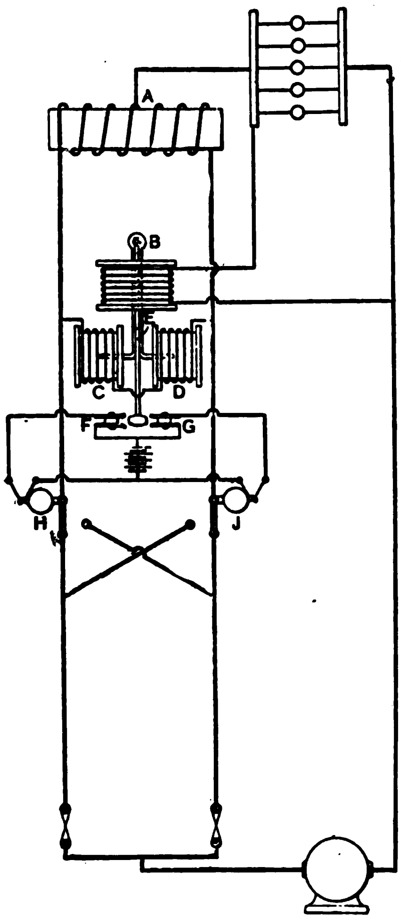

FIG. 3.—DUPLICATE MAINS SWITCH GEAR.

The apparatus consists of a vessel, *A*, containing mercury and some lighter liquid, such as oil; a miniature diving bell directly attached to the operating core is immersed in the mercury. This diving bell is divided into two compartments, *C* and *D*, by a thin diaphragm, and communication is established between the upper and lower compartments through a small hole in this diaphragm. A second hole is also made in the upper portion of the diving bell. It is obvious that a certain current will be required in the solenoid to overcome the weight of the core *B* and diving bell. If the core is lifted slowly the air pressure on the top of the liquid in the diving bell will be equal to the pressure in the outer containing vessel, and as this pressure will be transmitted through the oil to the mercury, the level of the mercury on the inside will equal that on the outside. If, however, the core is lifted more rapidly, the liquid, after passing through the small hole in the diaphragm, is wire-drawn, and, as a consequence, the pressure inside the diving bell will be considerably less than that on the outside, and a column of mercury will be added to the weight of the diving bell, the height of this column depending upon the rate at which the core and diving bell are lifted. If the core is lifted instantaneously none of the light liquid will have time to flow through the diaphragm, and, as a consequence, a vacuum will be produced in the diving bell on the underside of the diaphragm and the whole of the mercury in this will, in consequence, be lifted instantaneously.

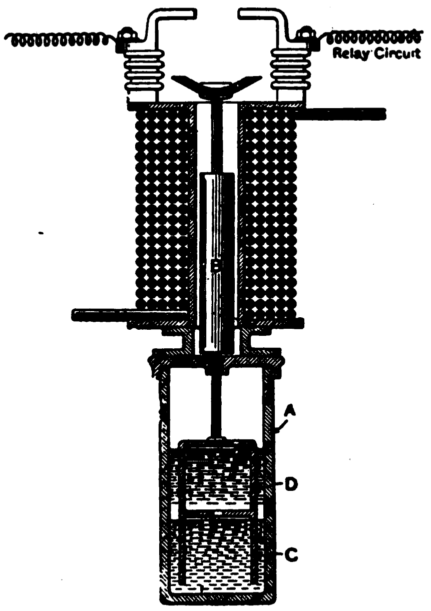

FIG. 4.—TIME LIMIT RELAY.

Verdet and Metais Gas Engines.—Figs. 5 to 9 taken from the *Mechanical Engineer* of London show a design of internal combustion engine, the joint invention of L. Verdet and A. Metais, of Paris. The engine works on the four-stroke cycle and exerts two driving impulses during each revolution of the fly-wheel. Referring to the illustrations Fig. 5 is a longitudinal section and Fig. 6 is a sectional plan of the engine. Fig. 7 is a cross-section through the cylinders, showing the inlet and exhaust valves for the gases. Fig. 8 indicates the operating mechanism of the exhaust valve and Fig. 9 indicates the mechanism of the inlet valves for air and gas. The motor is symmetrical with regard to its axis, *M* M_1. Two connecting rods, *I* and I_1, connect the crank shaft, *G*, with the two main pistons, *D*, by means of two auxiliary pistons, G_2, and two cylindrical rods, *H*, which each extend through stuffing boxes. Each set of parts comprises three chambers, viz., *A B C* on one side and A_1 B_1 C_1 on the other side. *A* and A_1 are the explosion chambers, and are provided with inlet valves, A_2, A_3, respectively for

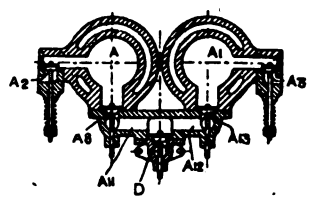

FIG. 7.

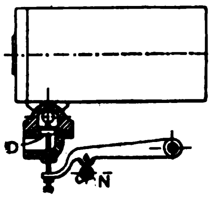

FIG. 8.

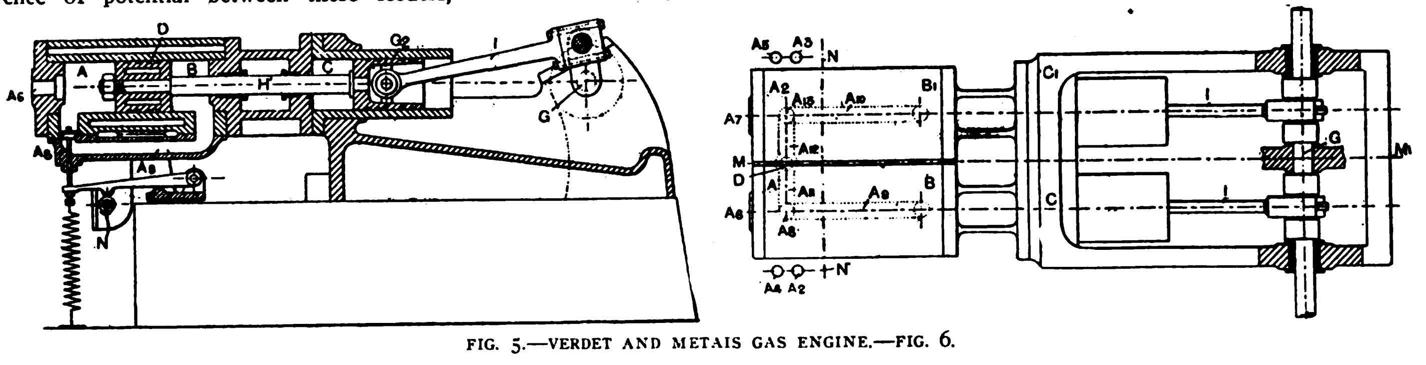

FIG. 5.—VERDET AND METAIS GAS ENGINE.—FIG. 6.

gas, and inlet valves A_4, A_5, respectively for air, and an igniter arranged at A_6 and A_7 respectively. B and B_1 are the expansion chambers, and C and C_1 the strain regulating chambers. D is the main exhaust valve. N is the half-speed shaft carrying the cams for operating the valves, these being all operated automatically by the half-speed shaft. The operation is as follows: The explosions in the chambers, A and A_1, are alternate, each being separated by a revolution of the fly-wheel; for instance, assuming an explosion in chamber A, the pistons move toward the right and at the same time the crank shaft receives a driving impulse. As soon as the pistons arrive at the end of their stroke the valve, A_8, is opened, and establishes communication through the ports, A_9, A_{10}, A_{11}, A_{12}, between the chamber, A, and the expansion chambers, B B_1. The gases thus expand in the chambers, B B_1, and act on the front surfaces of both pistons during the whole return stroke of the pistons. At the end of the return stroke the exhaust valve, D, is opened, and the gases escape into the atmosphere at a pressure much nearer to the atmospheric pressure than if they had beeen exhausted 180° sooner. The explosion then takes place in the chamber, A_1, the pistons again move toward the right, and at the end of the stroke the valve, A_{18}, is opened, and establishes communication between the chamber, A_1, and the chambers, B and B_1. The gases expand during the return stroke, and are then exhausted into the atmosphere, and so on. There is, therefore, an explosion of the contents of one cyqlinder during the stroke of the pistons from left to right, and an expansion in both cylinders during the stroke of the pistons from right to left. The first driving impulse (explosion) being, however, much greater than the second (expansion) the equilibrium is approximately re-established by means of the following arrangement: During the stroke of the pistons from left to right the pistons, G_2, move equally and produce vacua behind them, therefore they diminish the impulse due to the explosion; during the return stroke, on the contrary, the atmospheric pressure working on these pistons is added to the impulse due to expansion.

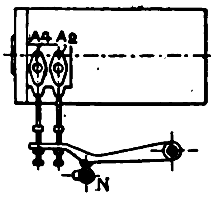

FIG. 9.

Parsons and Stoney's Direct-Current Generator.—The London *Mechanical Engineer* describes in a recent issue the direct-current generator devised by C. A. Parsons and G. C. Stoney, who claim several novel features; chief among which are a practically fixed line of commutation at all loads without sparking and an increase in the allowable ampere turns per inch diameter of the armature. Referring to the illustrations, A A are the field magnets wound with divided shunt coils, B B. The pole pieces, C C, are divided along the line X X. The fixed series winding is placed around the space, D, in which the armature revolves. The winding consists of two coils in series with the armature, the form of winding being that of

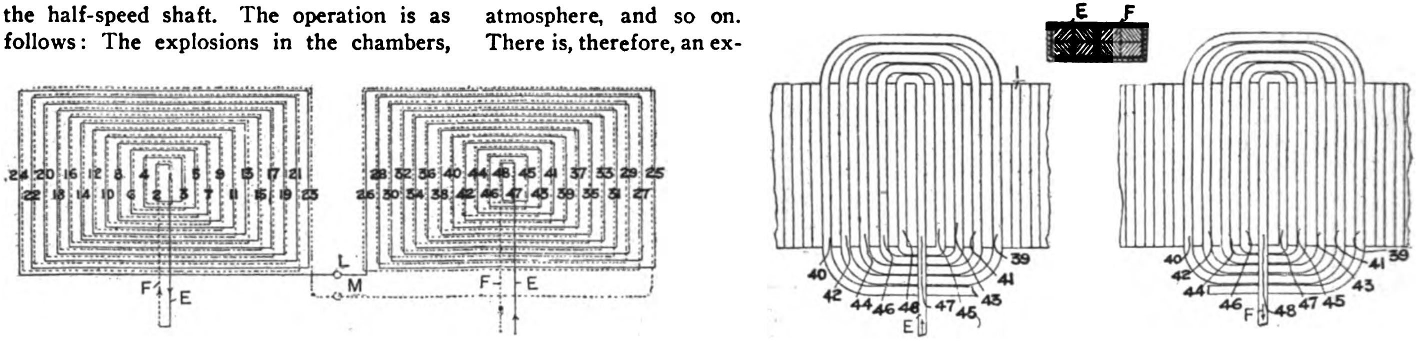

FIG. 12.—DIAGRAMMATIC VIEWS OF THE WINDING OF PARSONS AND STONEY'S GENERATOR.—FIG. 13.

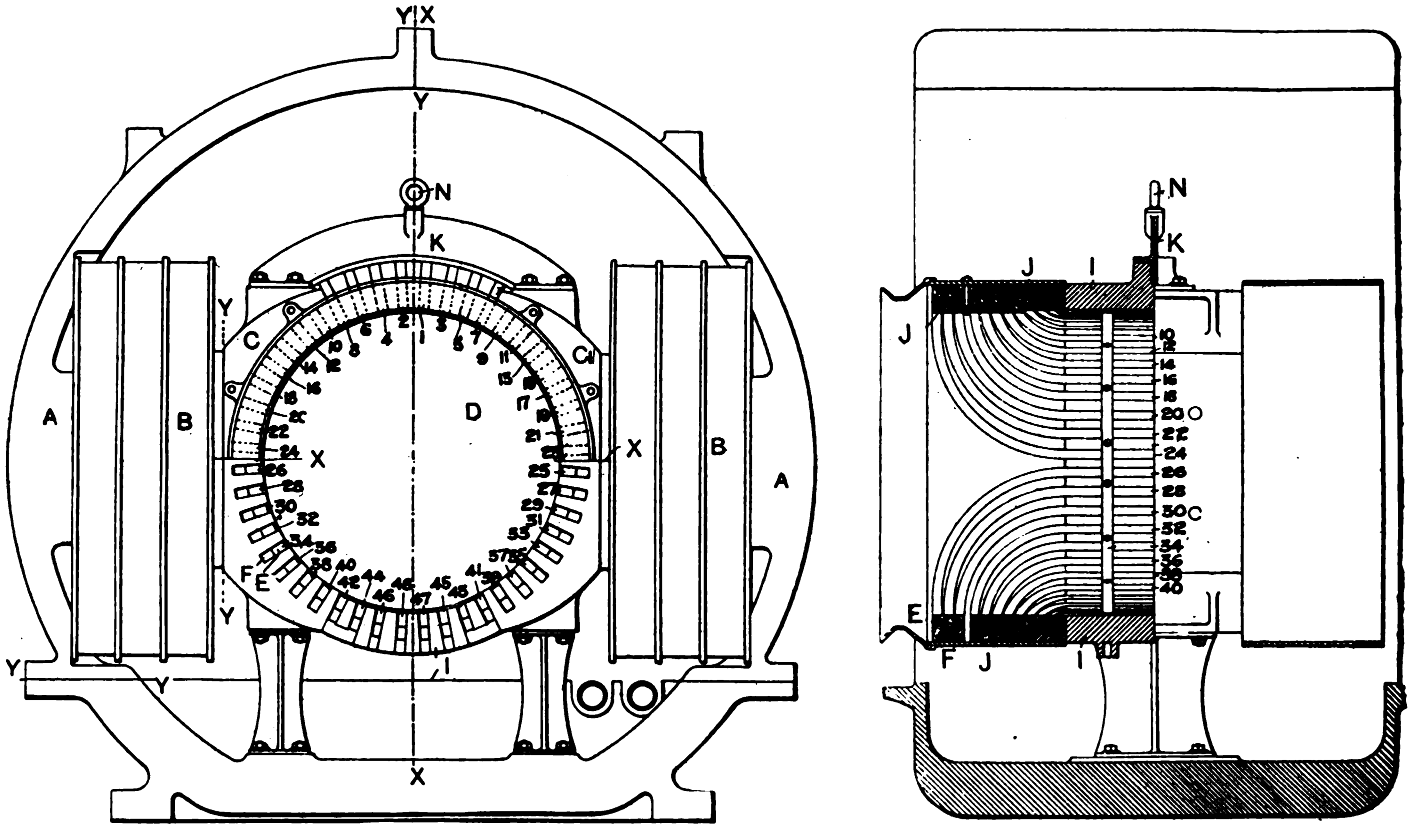

FIG. 10.—PARSONS AND STONEY'S DIRECT-CURRENT GENERATOR.—FIG. 11.

spirals on a cylindrical surface closely surrounding the armature, but giving clearance for its revolution. The coils, *E F*, where they occupy the polar faces, are embedded in open slots, 1, 2, 3, 4, etc., and between the polar faces are carried by non-magnetic segments *I* grooved for their reception. Beyond the magnets at each side the conductors pass in a direction perpendicular to the axis of the armature and are carried by cylindrical extensions, *J J*. The coils are shown diagrammatically in Fig. 12. The first coil, *E*, lies nearer to the armature in the slots, while the second coil, *F*, lies parallel with the coil *E* in the slots, but takes a different path between them, as shown in the developed views, Fig. 13, the true-developed view from the inside being obtained by superposing the left on the right. The coils *E* and *F* are shown in full and dotted lines respectively in Fig. 12. The current in the part of each coil in any slot in or between the pole faces will be opposite in direction to the current in the adjacent conductors in the armature. Fig. 13 shows a section of the conductors which tie in the slots as indicated in the lower half of Fig. 10. The coils, *E* and *F*, are divided along a horizontal diameter, *X X;* the upper half, 1, 2—23, 24, fits in the half-pole pieces, *C C*, and is also supported by the brass connecting piece *K* and extensions *J*. When it is desired to remove the armature the field magnet, *A*, with the shunt coils *B* are removed, the line of separation being marked by the dotted line *Y Y* in Fig. 10, binding screws *L M* connecting the upper and lower parts of the coils *E F* are then loosened, and the upper half of the coils with the piece *K* and extensions *J* can be lifted out by the eyebolt *N*. The polar plane of the coils *C F* coincide with the plane of commutation of the armature at no load.

High-Tension Fuses.—The *Elektrotechnische Zeitschrift* contains an account of a series of experiments made by a German manufacturing concern for the purpose of evolving a satisfactory fuse for high-tension circuits. The main difficulty experienced with high-tension fuses is that when the fuse melts metallic vapors are produced which are current conducting and form a bridge between the terminals of the fuse wire, resulting in an arc. The circuit, therefore, is not interrupted, the arc burning contacts and oftentimes flashing over to other metallic substances in the immediate vicinity. The main problem, therefore, is to extinguish the arc immediately. The first experiments were made with metallic fuse wire which was covered with a thick layer of tenacious cable compound. These were made into "cartridges," which gave excellent results up to 10,000 volts, passing 400 kilowatts. At greater capacities, however, they were absolutely useless, very violent explosions occurring. Fuse wire in oil was then tried, with fairly good results so long as a large basin of oil was employed. A fuse of convenient size was designed, having the form of a cylindrical glass tube of limited dimensions, which was filled with oil and contained the fuse wire. These, however, broke down with violent explosions, the oil being thrown out and the glass tube broken in many places. The violence of the explosion may be judged from the fact that glass tubes of 10 mm. thickness were broken and sheet iron of 5 mm. thickness was easily bent. The conductivity of the gas developed may be judged from the fact that at 5000 volts a spark jumps a distance of 70 cm. A fuse arranged as shown in Fig. 14 was finally tried with success. The features of this fuse are that the wire is placed in a chamber closed at the top and suspended at the bottom in oil. The fuse wire melts in air, but the explosive gases are driven downward into the oil. The glass tube is closed at both ends by metallic covers, the top cover being provided with holes for pouring the oil into the tube. The fuse wire is contained in the melting chamber proper, which is made of strong metal, as shown in Fig. 15. The chamber has a pinhole in the top through which the fuse wire enters, but is open at the bottom. The melting chamber is placed in the oil. The lower end of the fuse wire is electrically connected with the lower end of the glass tube and is also connected to this end by means of a spiral spring which holds the fuse wire in tension. The fuse wire itself is not in oil, so that when it melts, the spiral spring draws the lower end of the fuse wire downward and the explosive gases are immediately cooled in the oil. The result is that no arc is formed. The fuse is said to stand a continuous overload of about 50 per cent of the normal current and a short overload, up to five minutes, of about 70 to 80 per cent of the normal current. When loaded with double the normal current, it melts in less than two minutes. A number of the fuses have been installed in practice.

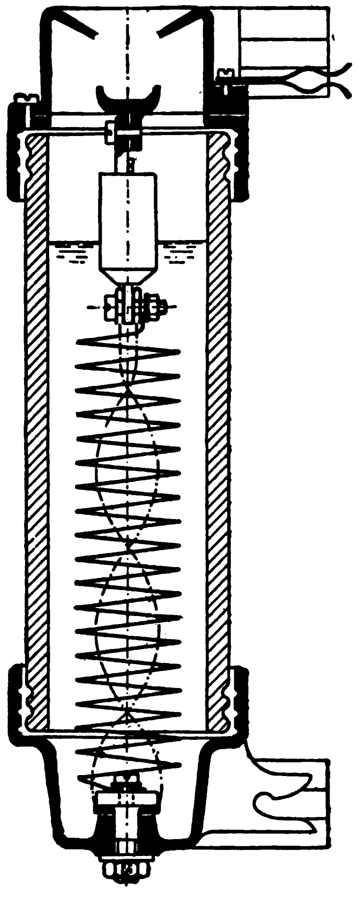

FIG. 14.—HIGH-TENSION FUSE.

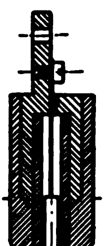

FIG. 15.

Single-Phase Wattmeter.—*L'Industrie Electrique* contains an illustrated description of improvements made in the Baltaut meter for single-phase systems. A U-shaped laminated electromagnet core is provided and the two ends of the arms are also U-shaped. The shunt windings are placed on the two arms of the main U and above these coils is placed a magnetic bridge, as shown in Fig 16. The series coils are placed on the arms of the two small U's, so that the polarities of the different magnets are as shown in Fig. 17. The combined action of the different coils develops eddy currents in a copper disc above the electromagnet. These react on the fluxes of the electromagnet so that a torque is produced which moves the needle on the dial of the meter. Since this torque is the result of the combination of the fluxes of the series and of the shunt coils, it is proportional to the energy to be measured. The angular speed of the disc is rendered proportional to the torque by adding a permanent brake magnet, which acts on the disc. The arrangements were formerly so made that the air-gap could be changed in order to vary the braking action. Now the air-gap is held constant. For regulating purposes the permanent magnet can be moved in the direction of the radius of the disc so that a greater or smaller flux

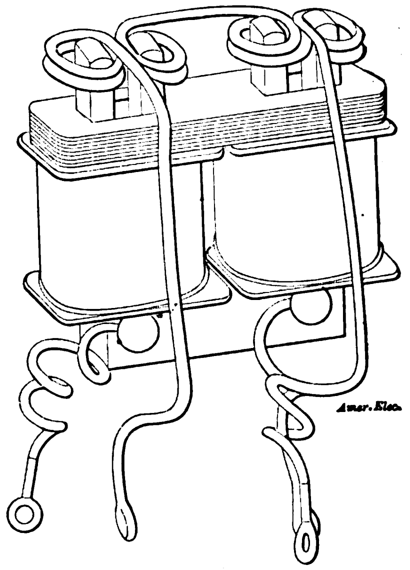

FIG. 16.—SINGLE-PHASE WATTMETER MAGNETS.

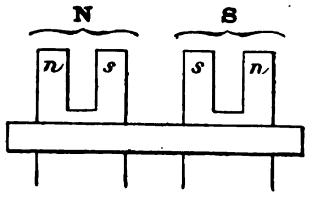

FIG. 17.

of the magnet acts on the disc. There is also provided a small iron piece which may be brought nearer the one or the other pole of the electromagnet, resulting in lack of symmetry of the field and in a small torque. If the meter shall be exact for a circuit with phase difference, it is necessary that the fluxes produced by the series and shunt coils respectively be in quadrature. This condition is fulfilled by placing on the poles, *N* and *S*, short-circuited windings which surround them completely. A 500-ampere meter of this type is started by a single 16-cp lamp.

SOME RECENT ELECTRICAL PATENTS

Self-Starting, Single-Phase Induction Motor. —Fig. 1 illustrates the latest attempt to provide a self-starting, single-phase induction motor; the inventor is M. C. Massie. The motor, *B*, is provided with a double-wound stator, like that of a machine intended to be started by means of a phase "splitter," and a rotor having a squirrel-cage winding and also an ordinary closed-circuit or ring winding. The latter is connected to two pairs of collector rings, one for running forward and the other for opposite rotation. A rotating field is set up in the stator by means of a peculiar transformer, *T*, having a stationary primary winding and two secondary windings, the latter mounted on a revolvable core like the armature of a motor. The two secondary windings are set at right angles to each other; consequently, when one is in position for maximum induction the other is in the neutral position. The transformer armature is mounted on the same shaft with, or otherwise rigidly driven by, the rotor of the induction motor *B*. The taps from the collector rings of the motor to its ring winding are located so that when one of the transformer secondaries is in the most favorable position and is delivering maximum e.m.f. to the corresponding stator winding on the motor, the polar axis of the rotor ring winding is in the most favorable position for torque, due to the field of the then active stator winding. The machine, therefore, starts up, and the rotation of the transformer armature produces a rotating field in the motor stator which is always just ahead of the polar axis of the rotor ring winding. The switch, *I*, is for reversing the motor by shifting the rotor supply current to the other pair of slip rings. The adjustable inductance, *I'*, is for regulating the torque of the rotor. At full speed the switch, *I*, is opened, leaving the machine a simple induction motor. Patent No. 763,774.

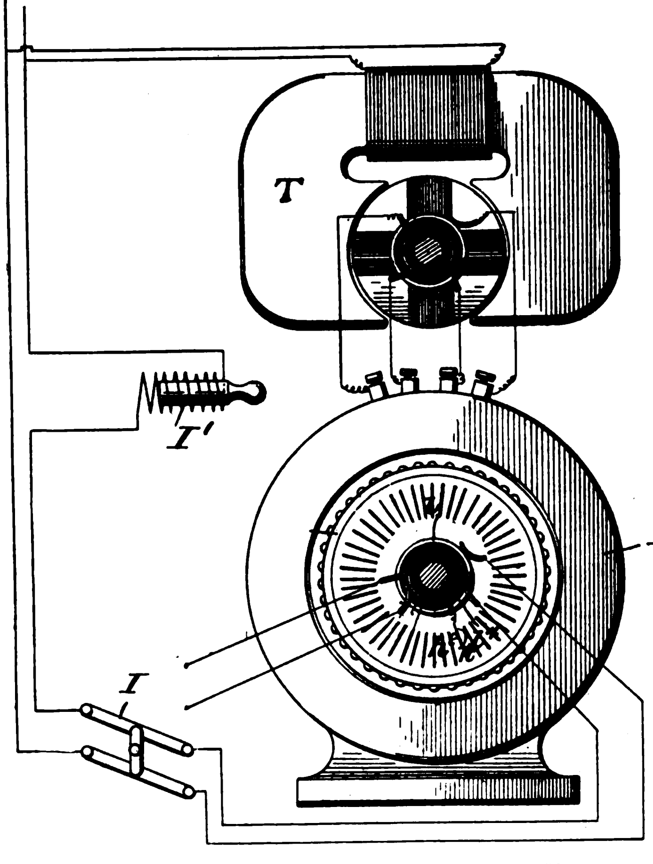

FIG. 1.—SELF-STARTING SINGLE-PHASE MOTOR.

Extinguishing Electric Arcs.—Numerous attempts have been made to provide means for entinguishing the arc drawn by the opening of a circuit carrying considerable current at moderate and high potentials, with varying success. One of the best-known means is the electromagnet, applied so as to blow out the arc. The inventor of this method, Prof. Elihu Thomson, has now devised another and simpler method, consisting of interposing non-combustible and non-conducting material between the electrodes: in short, choking off the arc mechanically. Fig. 2 shows the application to an automatic circuit-breaker. The main contacts are made, as usual, by means of a laminated metallic brush, 27, and the circuit is opened by means of supplementary contacts. In this case the latter are metal blocks, 2, 5, 5, the first mentioned block sliding between the other two. When the circuit-breaker is opened, the parts take the positions shown in the diagram; the arc which would otherwise follow from the stationary blocks, 5, 5, to the sliding block, 2, is cut off by the block of non-conducting material, 3, attached to the moving member, and the similar stationary blocks, 8, 8. The material used to cut off the arc is fused quartz. Patent No. 751,028.

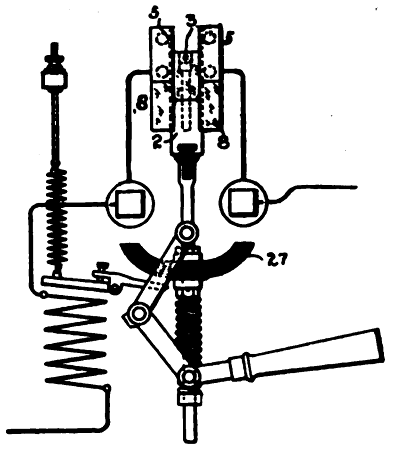

FIG. 2.—ELECTRIC ARC EXTINGUISHER.

NOTES.

Electric Traction on Lackawanna Railroad.—It is reported that the Lackawanna Railroad is contemplating the experimental operation of two storage battery cars on its Montclair branch. The cars are to be equipped with Edison storage batteries and the plan is to run the cars between Newark and Montclair during the middle of the day when traffic is light; the distance between the two cities is between 5 and 6 miles.

Power Consumption of Elevators.—The New York Edison Company, in a recent issue of its admirable little *Bulletin*, gives the following figures taken from tests of direct-current passenger elevator motors:

No. of test.	Lifting Capacity	Speed per minute	Days Covered by Test	Average Consumption of Current per car mile
	Lbs:	Feet:		Kw-hours:
1	1500	175	31	2.2
2	1500	175	29	1.67
3	2000	225	21	1.54
4	2000	225	21	1.77
5	2000	150	21	3.6
6	2000	250	30	3.12
7	1000	250	26	2.14
8	1000	250	30	2.41
9	1500	250	24	2.97
10	2000	250	30	3.38

Underwriters' Rules for Electric Car-Wiring. —The Underwriters' National Electric Association has issued a supplement to the Code relating to electric wiring, the supplement containing rules covering the wiring of electric cars. As this is a rather special branch of electric wiring, copies of the supplement have not been distributed generally and the first edition has been limited to 10,000 copies. Anyone needing a copy of the supplement may obtain it on application to the National Board of Fire Underwriters, 32 Nassau Street, this city.

International Electrical Congress Plans.—The American Institute of Electrical Engineers has arranged a most attractive tour for the pleasure of foreign engineers who are expected to attend the St. Louis Exposition during the International Electrical Congress. This tour includes visits to Schenectady, Montreal, Niagara Falls, Chicago and Springfield, Ill., on the way to St. Louis. At the close of the Congress, the tour will be resumed, taking the participants to Pittsburg, where the Westinghouse factories will be visited, thence to Washington for a day's sight-seeing, to Philadelphia, and back to New York. The special train making this tour will leave New York at 8.45 a. m., September 6th, arriving at St. Louis at noon, September 11th (Sunday). The Congress opens on the following morning and will close on Saturday, September 17th, as stated in previous issues. At 8 p. m., the same day, the special train will leave St. Louis for Pittsburg, Washington, etc., arriving at New York at 5.30 p. m., Wednesday, September 21st. Arrangements have been made whereby tickets may be bought to cover the entire itinerary, including hotel accommodations in the various cities visited, for $150 each.

Wireless Telephony by Means of Hertzian Waves.—Some interesting experiments were recently made by a Spanish engineer, Mr. G. J. de Guillén Garcia, together with his son. In connection with some wireless telegraphy researches the son of the experimenter happened to note that in the telephone of the Tommasi coherer located at the receiving station, there was a sound difference according to the air-gap in the interrupter of the Rhumkorff apparatus. This suggested the idea that a similar apparatus would be susceptible of transmitting the human voice to a distance without the agency of the wire, and after some delay Mr. Garcia tried the experiment.

The experimental arrangement is a rather simple one. At the transmitting station there was a Rhumkorff coil giving a spark 1 3-16 inches in length, as well as the necessary oscillator, a small antenna and a grounded conductor. Between the induction coil and a small battery of Grenet cells there was a special microphone, acting both as transmitter and as interrupter. The automatic interrupter of the induction coil was stopped and the condenser was used for enhancing the oscillator spark.

At the receiving station, there was a Tommasi coherer connected to the receiving antenna and the grounded conductor. In a telephone receiver the noise produced by the Hertzian waves on traversing the coherer was plainly heard. On applying the mouth to the microphone and singing or speaking, every sound vibration was attended by an interruption in the passage of the electric current through the primary circuit of the induction coil, the number of sparks at the oscillator thus being varied. The underlying principle shows, therefore, some analogy with the mechanism of an ordinary telephone.

The results so far obtained in the reproduction of singing tones are said to be quite satisfactory, but the transmission of speech leaves much to be desired. The weak point seems to be the difficulty of designing a microphone of sufficient vigor, so to speak. Mr. Garcia, it is true, has remedied the imperfections of his apparatus to a certain extent by the use of a condenser; this, however, could not be carried too far, lest electric arcs be formed.

Experiments With 70,000-Volt Direct and Alternating Currents.—Some interesting tests were recently made by the Compagnie de l'Industrie Electrique et Mécanique, Geneva, Switzerland, with very high-tension direct currents. Three direct-current dynamos, one of which gives 20,000 and each of the other two 25,000 volts, were connected in series in the laboratory of the company, to get 70,000 volts. Each of the three dynamos had a maximum capacity of 1 ampere, so that 60 to 70 kilowatts were available; this was more than sufficient for obtaining comparative data. The behavior of insulators with respect to direct and alternating current was especially investigated, a special alternator being constructed to yield 75 kilowatts. The conditions were rather unfavorable for the direct-current tests on account of the armature coils being arranged in the slots of a toothed ring, so that the self-induction was increased and current oscillations produced. In spite of these disadvantages, the results of the experiments are highly in favor of direct current. All the insulators used were found to stand much higher direct-current than alternating-current voltages, and the same may be said of insulating substances submitted to piercing tests. Moreover, no considerable heating effect was observed in the case of insulators exposed to the action of direct current, while the opposite was true with alternating current; this seems to be due to the absence of any capacity effects in the case of direct current. With direct current the crackling noise produced by alternating current on approaching the limiting tension the insulator is susceptible of was not heard, and no glow was noticed until the breakdown distance was approached quite closely.

Ordinary insulators, such as those used for telegraphic purposes, as well as insulators such as have been used for years past in connection with power transmission over moderate distances, were not perforated by 65,000 volts direct-current e.m.f. The tests indicated that the porcelain, however, should be well vitried and homogeneous, whereas the thickness matters little. Glass was found to be difficult to perforate with direct current, ordinary white glass of 0.3 mm. withstanding very well potentials as high as 25,000 volts, while a disc of plate glass was found to stand upward of 60,000 volts direct-current tension. When the insulators were tested in the laboratory, being protected against atmospheric influences, the limiting voltage could as an average be driven up to 1.63 times that in the open air after 24 hours of dense rain.

Convention of the Canadian Electrical Association. —At the fourteenth annual convention of this association, held recently in Hamilton, Ontario, there was a very large attendance, and a number of practical papers were read. Among these was a most instructive one by Mr. W. L. McFarlane, on "Alternating vs. Direct-Current Arc Lighting System." The author stated that, for reasons apart from arc lighting, the tendency at present in equipping electric power stations is toward the installation of alternating-current generators of large capacity. The source of power may be water or steam, or a combination of both; and when, as is often the case, a combination of engines and water power has to be used, transformers and lamps, or motor-driven arc dynamos are possible as in the other two cases, there being also possible the arrangement whereby the arc dynamos are operated from line shafting to which are connected both an alternating-current motor and an engine, by means of suitable clutches or quills, either the motor or the engine being used to supply the necessary power to the shafting. Generally speaking, there are four systems of series arc lighting at present in use, as follows: (1) The small arc dynamo supplying about 50 open lamps at 9.6 or 6.6 amperes. (2) The larger and more modern arc dynamos supplying as many as 175 open lamps in series or by the multi-circuit arrangement. (3) Large arc dynamos wound for 6.6 amperes for supplying current to enclosed lamps. (4) Transformers to which are connected circuits having as many as 100 constant-current, series-alternating, enclosed arc lamps.

The maximum candlepower of the open arc is higher than that of the enclosed arc, but the light is not so steady owing to the more frequent feeding of the carbons, their poorer quality, and the action of the wind on the arc. Owing to the shortness of the open arc, and to the fact that most of the light comes from the crater of the upper carbon, this light is in a downward direction, being greatest at an angle of about 45°, while a large area under the lamp is poorly lighted and affected by shadows. In the enclosed arc the wandering of the arc is the main cause of what variation there is in the light, but by the use of an opal inner globe these variations are greatly reduced. The increased length of the enclosed arc allows the light to diffuse in a more horizontal direction, the result being much less light in the immediate vicinity of the lamp, but a slightly increased amount midway between lamps.

The "Question Box," edited by Mr. A. A. Dion, of Ottawa, created a great deal of interest and brought to that gentleman a well-merited vote of thanks from the association for the time and trouble devoted by him to preparing the questions and securing the answers in the published volume of the Question Box.

The election of officers resulted as follows: Mr. K. B. Thornton (Montreal), president; Mr. A. A. Wright, M. P. (Renfrew), first vice-president; Mr. George Black (Hamilton), second vice-president; Mr. C. H. Mortimer (Toronto), secretary-treasurer. The Executive Committee consists of Messrs. A. B. Smith, Gordon Henderson, J. A. Kammerer, John Murphy, J. J. Wright, A. A. Dion, B. F. Reesor, C. B. Hunt and Fred Thompson.

The Variable Speed Motor.

The article on this subject which we print elsewhere in this issue emphasizes several points of interest in connection with speed regulation in electric motors. One of these is the fact that regulation by varying the counter e.m.f. per revolution, without varying the current capacity, is the only method which enables the motor to develop its full power at all speeds. This, of course, is not news to anyone at all familiar with motors. It does not appear always to have received as much consideration as it might have, however, in view of the well-understood fact that the availability of full power at low speeds is a very great advantage in some classes of motor application. As Mr. Hemingway states plainly enough, the bugbear in securing wide ranges of speed by means of ordinary field variation is that at the higher speeds one encounters serious commutation difficulties; and the most obvious method of varying the counter e.m.f. by varying the number of armature conductors is utterly impracticable beyond very small limits. His method of varying the counter e.m.f. by applying an auxiliary magnetic field to the armature and regulating this to assist or oppose the e.m.f. induced by the main field throughout a graduated range is certainly ingenious; whether or not it would be practicable from a purely commercial standpoint can be determined only by trial.

There are at least two practical machines on the market, however, in which the counter e.m.f. of the motor is regulated over a wide range without developing any difficulty at the brushes. In one, the field magnetism is varied over the central part of the pole-face without appreciably affecting the density of the pole-tip fringe and without involving appreciable field distortion; the field variation is effected by purely mechanical means. This machine, obviously, embodies one solution of the problem of securing full output at all speeds. In the other there are two armature windings, each of the same current-carrying capacity, but containing very different numbers of conductors; these are connected to two commutators, and the controller puts either one or the other winding in circuit alone, the two in series cumulatively, or in series differentially. The result is four speeds, covering quite a wide range, at all of which the full output is available; intermediate speeds are obtained by varying the field excitation slightly. Obviously, the machine commutates just as well at one speed as another, excepting those at which the field is weakest; it is, of course, designed for commutation at those speeds, and therefore commutates properly at all others.

Mr. Hemingway's suggested machine evidently is analogous to this last-mentioned motor so far as results are concerned, although one of these results is obtained in a different way, and does not cover so wide a range. He varies the effective proportion of the total armature winding by inducing either an assisting or an opposing counter e.m.f. in it with the auxiliary field magnet poles, and gets intermediate speeds by grading the auxiliary field strength; the latter is practically the same as grading the strength of a single field system.

In all cases, excepting possibly the type embodying field variation by altering the flux in the central part of the pole-face, a multispeed machine giving its rated output at all speeds must necessarily be heavier and more expensive than a constant-speed machine of the same output. It is merely a question as to what method entails the least additional weight and shopwork to produce the motor and its controller. As to the possible exception just noted, we have not sufficient "inside information" to enable us to express an opinion; in the abstract we should think that the foregoing statement would apply to any type, on the principle that one cannot expect to get something for nothing.

◆ ◆ ◆

Erratic Engineering Development.

It is interesting and curious to note how indirect is the development along some engineering lines. The alternating-current generator, for example, was the first type to be actually built for commercial purposes. The old "Alliance" alternator of Du Moncel, which was used for lighthouse service from 1863 for many years, was the development of a machine devised by Nollet in 1849. Probably the first direct-current machine of any considerable output was the one built by Holmes and exhibited at an Exposition in 1862, but that was remodeled a few years later into an alternator. Notwithstanding this excellent early start, direct-current apparatus reigned supreme from the time when electric lighting really began to amount to anything until the invention of the transformer—or, rather, the waking up of Gaulard and Gibbs to the fact that the long-known induction coil is a transformer.

The steam turbine is another example of delayed development. Hero's revolving sphere was essentially a steam turbine, of course. The fundamental features of the present De Laval and Parsons turbines were disclosed in an English patent issued to one Pilbrow in 1843, and the principle of compounding for velocity, embodied in the Curtis and Stumpf turbines, was described by Robert Wilson in 1848. Most of the early turbine inventors, too, seemed to have very clear-cut and comprehensive ideas as to the practical requisites of successful turbine design, but none of them ever succeeded in reaching an industrial status. It is thought by the editors of *Engineering* (London) that one of the principal reasons for this failure might have been the lack of facilities for doing the extremely accurate machine-tool work that is indispensable to successful turbine operation. It is highly probable, however, that the inherently high velocities necessary to good economy had much more to do with retarding turbine development than any other one feature; the transition from seventy-five to several thousand revolutions per minute was entirely too startling, even if it had been possible to get the grade of workmanship essential to high speeds and small clearances.

The belated recognition of the gas engine is still another curious feature of engineering progress. It has been about forty years since Beau de Rochas pointed out the vital requisites to economical gas engine operation, and we are just beginning to get a dim conception of the actual possibilities of the machine. One reason for this, of course, is that industrial conditions have only within comparatively few years been such as to force attention to the problem of cheapening power conversion; this, too, is one of the reasons for the delayed developments in the other branches mentioned. Still, it seems almost absurd to have allowed the gas engine to lie practically unutilized for almost half a century while everyone concerned knew at least the superiority of the machine as a converter of heat energy into mechanical work.

◆◆◆

High Potential Direct Current.

In another column will be found a brief account of some tests on insulators made by the only advocate of direct-current high-tension transmission in the world: M. Thury's Compagnie de l'Industrie Electrique et Mecanique, of Geneva, Switzerland. These tests show, as one might naturally expect, that many of the drawbacks incident to the insulation of high alternating voltages are much less formidable in the case of direct current, and some of them disappear entirely. Though one is strongly tempted to apply the current slang expression of forlorn hope: "What's the use?" in this case, it is impossible not to admire the courage and persistency with which this lone enthusiast has followed up his convictions; one even feels a tendency to share M. Thury's hopeful faith in direct-current transmission, notwithstanding its apparent lack of scientific justification. And when the intrinsic attractions of direct-current transmission are considered, it is really not to be wondered that strong efforts have been made to reduce it to a practical status.

It is, of course, a matter of common knowledge that the fundamental obstacle in the way of successful direct-current transmission is the commutation of high voltages. The flexibility of alternating-current transformation is a tremendously advantageous feature of that class of plant, but if direct high potentials could be produced by machines of a few thousand kilowatts capacity it is very safe to say that many engineers would put up with the expense of installing and maintaining direct-current rotary converters rather than struggle with the difficulties attendant upon very high tension alternating-current transmission. We are free to confess that the solution of the high-voltage commutation problem seems hopelessly remote; even commutation at ordinary voltages has not been brought to a point where there is any unanimity of opinion as to the requisites for success. Nevertheless, we sympathize with M. Thury in his struggle and sincerely hope he may conquer the enormous odds against him and compel complete success.

The Value of Education.

A reader recently asked the question: "How can a graduate of a correspondence school expect to get a position when there are so many experienced engineers looking for work?" The answer is obvious: he can't—merely on the strength of being a technical graduate. But if the school is a good one and the man has the right qualities his chances of getting a good position will be about ninety-nine times greater than if he did not have the learning. Technical education not only confers the benefit derived from all classes of systematic mental training but it enables the possessor to save an enormous lot of valuable time in "getting on," by avoiding the mistakes that would otherwise be inevitable and by attacking his work intelligently and confidently instead of dubiously and blunderingly. We do not believe there is a solitary position in the whole field of engineering the holder of which cannot, by means of education, immensely increase the chances of improving his lot.

It is a grave mistake, however, to imagine that the possession of a diploma or other certificate of technical learning is a guarantee of flowery success. Hundreds of misguided parents are bestowing on their male children special educational advantages which will merely serve to condemn them to a professional mediocrity that is more humiliating than the lowest grade of manual labor. The personal qualities and natural fitness of a man have vastly more to do with his success than mental training. All this, however, does not in the slightest degree affect the question of whether or not education is advantageous to a man who is, or expects to be, engaged in a certain line of technical work; there is no more room for doubt on this score than there is reason to question the law of gravitation. Given two men of equal inherent worth, one having special education in his line of work and the other being without it, with absolutely equal chances otherwise, the educated man is as sure to leave the other far behind as a rock is to fall toward the earth when released in air.

◆◆◆

The Alternating-Current Cycle.

Any succession of operations that brings the operator back to the starting point, ready to repeat the series, is a cycle. Thus, if one should take an elevator at a given floor of a building, ride up to the top of the building, then down to the basement, and then back up to the floor at which he started, he would have passed through a "cycle" of elevator travel. Similarly, when a gas engine, starting at the point when the cylinder is empty, takes in a charge of gas and air, compresses the charge, ignites it and lets the expansion of gases drive the piston forward, and finally exhausts the burned gases, leaving the cylinder empty and ready to take in another charge, it has passed through one cycle of its routine operation. Now, when an alternating current rises from zero to its maximum value in one direction, falls back to zero, reverses and rises to maximum in the opposite direction, and falls to zero again, it has passed through one cycle of its regular operation. The cycle was not complete when the current fell to zero after rising to maximum the first time because it had not been through the rise to maximum in the other direction and was, therefore, not precisely at its original starting point, ready to rise in the first direction again.

DESIGN FOR A CHANGE SPEED GEAR FOR MOTOR-DRIVEN VEHICLES.

BY J. E. PFEFFER.

Up to the present stage of development of the gasoline motor vehicle it has been found impracticable to connect the motor unalterably to the driven axle. It has been, and probably will long be, necessary to provide some form of conveniently operated mechanism for varying at will the ratio of the motor speed to the speed of the traction axle. In order to accomplish this end with the greatest degree of efficiency, convenience and noiselessness and with a minimum of wear and tear the resources of mechanics have been thoroughly canvassed, with the result that numerous means, which could by any possibility serve the purpose, have been adapted and given more or less trial. Among the ways and means of effecting the movements upon cars that have to be controlled by non-mechanical, or at least somewhat unskilled persons as well as the "handy" expert, the sliding clash gear system has proved by far the most popular of all methods for use on high-grade motor cars, due to its compactness, ease of enclosure, positiveness and strength, and requiring no adjustment in its entirety. It is, at times, objected that it is difficult to force the gears into mesh without delay, noise and battering of the opposed tooth faces. This is true, however, only when gears of too small pitch, improper tooth outline and badly beveled faces are employed.

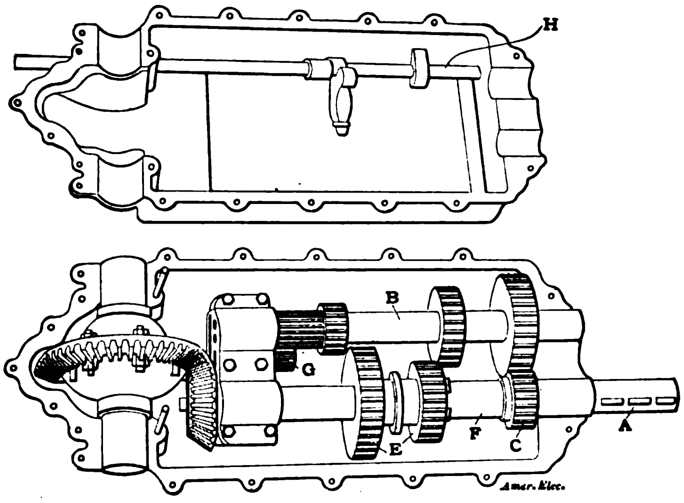

FIG. 1.—CHANGE SPEED GEAR AND CASE.

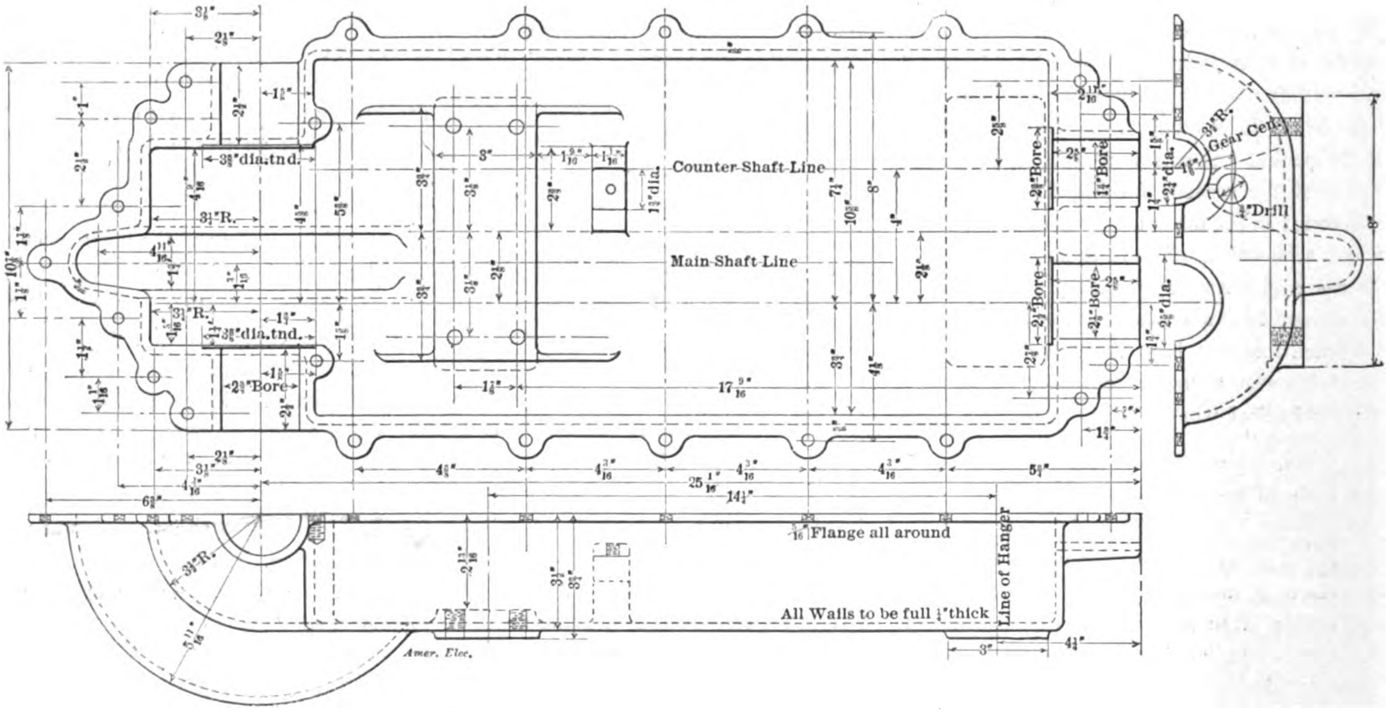

FIG. 2.—GEAR CASE DETAILS.

In this connection it is well to note that in these speed-changing gears employing two parallel shafts with the speed ratio varied between them, the sums of the diameters of any pair of gears which are ever in mesh must be equal. As the name indicates, in this sliding clash gear system the gears are not maintained in permanent mesh for any two speeds controlled thereby, but different pairs are engaged at will by a sliding motion of the sliding gear, causing either the teeth of the one gear to enter the tooth spaces of the other, or a similar action between the crab teeth of clutches for the case of the direct or high-speed arrangement.

The accompanying working drawings show a design used on various types of touring cars, ranging from 20 to 30 horsepower, which is so constructed that it may be readily adapted to any side chain driven car without any change in detail whatsoever. It is very simple, has 3 speeds forward and 1 reverse, operated by 1 lever. The speed ratios are 1 to 1, or direct, on high speed, 1¾ to 1 on second speed, 4 to 1 on third speed, reverse 5 to 1. The full movement of the shift gear in making these various combinations is 7 inches and its entire operation depends upon a one-movement connection, termed the one-lever control. A good idea of the assemblage of the gears and shafts in position in the lower case can be gleaned from Fig. 1. The main shaft, *F*, here takes a bearing inside the gear wheel, *C*, which in turn is rigid with the stub shaft, *A*, to which the motive power is to be connected. The wheel, *C*, has jaw clutch members formed on its inner side to correspond with those on the rear side of the sliding gear, *E*, which is carried upon the shaft, *F*, capable of sliding along its length but made fast against turning upon it by virtue of the squared portion of the said main shaft. The engagement of these corresponding jaw clutches gives the direct or high speed, when none of the spur gears are transmitting power, since the power shaft, *A*, is now directly coupled to the cross shaft drive pinion.

For the intermediate, the slow speed and the reverse, a lay shaft, *B*, parallel to the main shaft, has fixed upon it three spur wheels, the use of either one of which in the transmission of power to the bevel drive pinion, depending upon the longitudinal position of the sliding gear, will serve to get one of the required reduction ratios between the power shaft and the bevel drive pinion. These gears are of such size and so spaced along the lay shaft that only one pair of gears can be brought into mesh at the same time when the sliding gear on the main shaft is moved. The arrangement of this system of variable speed gears is such that by progressively moving the sliding gears the smallest gear on the main shaft first comes into mesh with the largest gear on the lay shafts giving the low gear or greatest reduction ratio. As these gears slide out of engagement, the larger of the sliding gears on the main shaft is ready to enter its teeth into the tooth spaces of a smaller one on the lay shaft giving a higher gear and a smaller reduction ratio. The spacing is such that when one gear slides out it will not come into contact with another by the continued motion of the sliding gear. The reverse is obtained by sliding the main shaft gears into mesh with the idler, *G,* Fig. 1, which in turn is constantly engaged with a suitable gear on the second shaft.

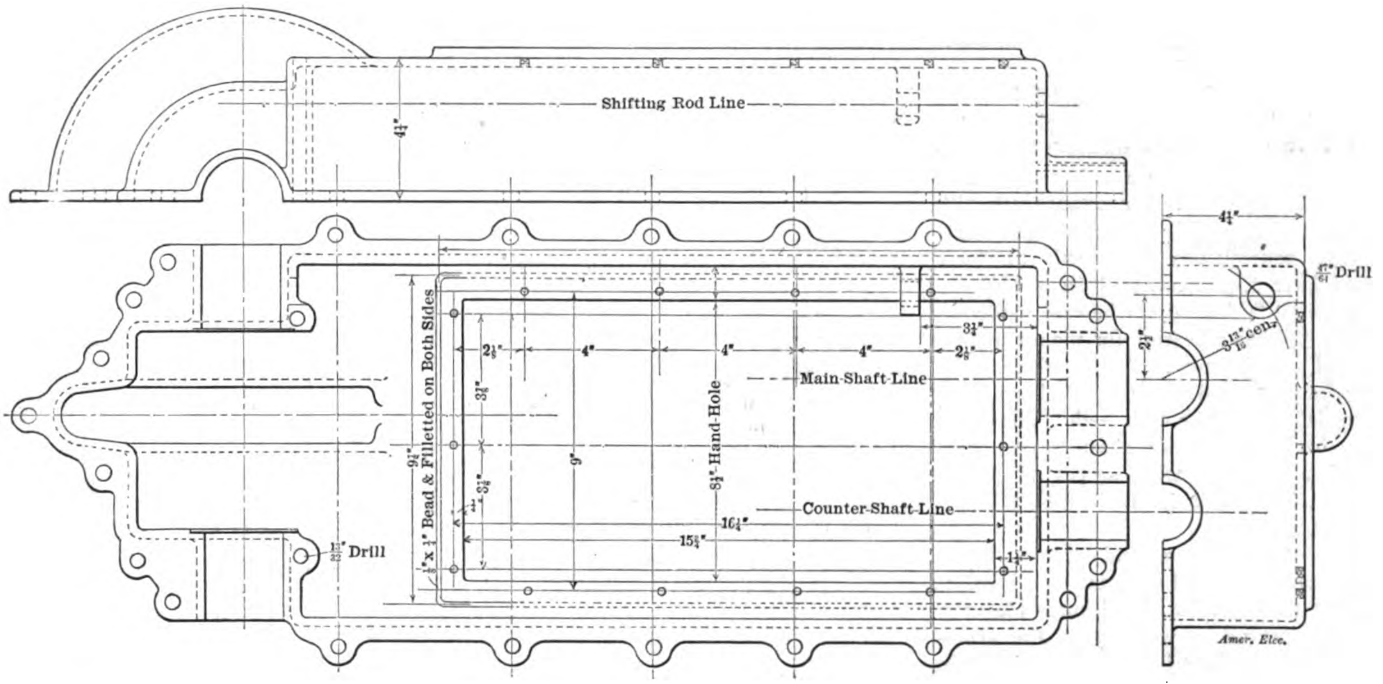

FIG. 3.—GEAR CASE DETAILS.

The case for the transmission system consists of two castings, marked Detail "Y" and Detail "Z." These are intended to be made of aluminum-zinc alloy containing about 25 per cent. of zinc. They can be made of cast iron where it is desired to reduce the cost rather than the weight, and should then be made considerably thinner (about 3-16 in. thick). The horizontal joint between the bottom and cover of the case passes through the center of the main bearings. The bottom portion, Detail "Z," has two downward projecting bosses to serve as feet for bolting it to cross hangers stayed to the side members of the main frame of the car. By this arrangement suitable hangers can always be made to properly hang the gear without any alteration on the case.

In finishing Detail "Z" the hanger bosses are first to be planed to the given size, then the bolting surfaces of both halves should be finished. The bolt holes in the bolting flange may then be drilled and the two halves bolted together, after which the seats for the various shafts may be bored. This latter boring should, of course, be done with one setting, and particular care be exercised to have the cross and other shaft bearings at right angles in the same plane. Particular care should also be taken to make a tight job of the joint in the case without the intervention of a separate gasket or packing, relying only on the careful surfacing of the metal and the bolts for drawing the parts together. The case containing studs, Detail "O," introduced for the prevention of any springing apart of the case about the bevel gears, should be tightly screwed into the case bottom to such a length as to allow about 1-16 in. extension above the nut after the cover has been slipped on and the nuts screwed up firmly.

The bearing pedestal supporting boss in the bottom of Detail "Z" should have ample filling provided for at the corners in making up the pattern, in order to insure the finishing indicated to provide a seat and in consequence avoid any transverse motion in the pedestal. The tap holes for this should be drilled before the drilling of the corresponding holes in the pedestal, so that they may serve as guides in laying out the latter.

The inspection hole in the top of the case cover is to be covered with Detail "V," made out of sheet steel. No finishing is here necessary for the joint other than rasping out the contact surface within the bead on Detail "Y" with a hand surfacing tool. Practice has demonstrated the advisability of this, for any oil that may find its way through the joint proper is satisfactorily restrained by the housing provided by the surrounding bead. However, in extreme cases, as when using a very light oil, small asbestos rope packing may be inserted around the outside of the cover screws.

The bronze bushings, Details "E," "F," "G" and "T," for the shaft bearings should be carefully fitted to the different seats in the case, to avoid any possible leakage of oil or looseness in the bushings. These bushings are held fast from turning by dowel pins (Detail "W") inserted in the case bottom to match holes given in the bushing details. Detail "F" is closed at the outer end by a separate piece as shown, to provide a dust-proof, oil-tight box for this dead ended shaft. All oil grooves in bushings shown in detail should be fully observed to insure the necessary lubrication for these close-fitted bearings.

The idler shaft, Detail "N," supported by the bearing pedestal, Detail "R," and the lug in the case bottom, is held fast by the retaining set screw in the top of said lug. In placing this shaft the gear centers should be observed and the idler gear made to revolve freely without lateral movement on the shaft.

The gear shifter shaft, "Detail "P," shown in position at *H,* Fig. 1, is contained in bearings in the ends of the case cover and specially located lugs on the side of the case cover. This drilling should be done with a long shank drill from one end to insure proper alignment. While inserting the shaft, the shifter fork, Detail "Q," should be slipped on while being held in the groove between the gears on the sliding gear, Detail "D." To locate this fork correctly along the shaft, place the shifting gear in the clutch, *C,* Fig. 1, with the shifter shaft about 1-16 in. through on the outside of the cross shaft end of the case, and tighten up the set screw in the shifter fork firmly.

The bearing pedestal, Detail "R," should first be planed at the bottom, then the surfaces of both the pedestal and the cover, Detail "S," where they bolt together should be finished. The bolt holes in these bolting flanges may then be drilled and the two parts screwed together, after which the bearing seats for the shafts and the seat for the idler gear shaft may be bored. Dowel pins should then be placed in the bottom of the pedestal bearing seats so as to correspond to holes in Details "G" and "T" of the bushings. One end of the main shaft-bearing hub on the pedestal and cover is indicated to be finished in order to supply an end-thrust bearing surface for the bevel-drive pinion. This finishing should be done with the pedestal and cover bolted together after the boring of the bearing seats in same. Before drilling the retaining set screw holes on the base of Detail "R," the bottom ends should be fitted carefully to the planed seat in Detail "Z," after which the set screw holes can be marked to correspond to tap holes in the case bottom with shafts in position.

The engine-driven pinion, Detail "C," is provided with a stub shaft and a set of crab teeth for the direct-drive engagement with the sliding gear. To the stub shaft the motor connection with the intervention of an operating friction clutch is made, either by keys or by the squaring of the stub shaft to which the square-holed sleeve of the clutch direct or a universal joint is fitted. This pinion is in constant mesh with the gear, Detail "I," as is also the reverse pinion, consequently the teeth of these gears have square-cornered faces, and except Detail "C," need not be case hardened. Detail "C" has a bearing for the main shaft bushed with bronze, as shown, which bushing should extend out to be flush with the extended end of the crab teeth. The clearance back of the main shaft end when in position in this bearing serves adequately as an oil reservoir for lubricating this important bearing.

The shifting gear and clutch, Detail "D," requires special attention and involves a great deal of labor, but insures the most reliable method of working by the avoidance of all feather key work in the most important member. The crab teeth on this should be carefully fitted to engage freely with Detail "C," and should be slightly beveled off at the outer extended corner, as indicated, so that a free sliding over may be had on the bushing sleeve during engagement with Detail "C." The faces of the teeth of this sliding gear should be carefully beveled and hardened, so as to enter into mesh with their mates readily and not be subjected to deformation; then, as the operating clutch of the engine is always out and no power being transmitted when shifting of gears occurs, these gears have no power but their own momentum and consequently their teeth should enter the tooth spaces of their mates at all times without danger of breakage.

The lay shaft second speed gear, Detail "J," the third gear, Detail "K," and the reverse idler pinion, Detail "H," should for the same reason as given for the shifting gear have their tooth faces beveled and hardened.

The distance sleeves, Details "L" and "M," are specified to be of cast iron, but can be made of any convenient tubing fitted

over the shaft, as no lateral thrust is to be withstood.

For the keying of the stationary gears the Woodruff system has been specified throughout, and though taper flat keys can be employed successfully at the hands of careful workmen, the other arrangement is more readily and cheaply applied when the proper facilities are at hand, and it has in general practice given more reliable results.

The differential or compensating gear on the cross shaft shown in position in connection with the bevel gears in Fig. 1, was originally specified to be the Brown-Lipe No. 8. Any other of the standard makes, of a size capable of transmitting this power, may, however, be used without change of details. Manufacturers of differential gears furnish the bevel gears complete with side bearings to fit either in the rough or finished, so that with the dimensions of the case supplied them no trouble should be experienced. These outfits as supplied by the markets to-day are recognized standards and no attempt has been here made to supply a special design, which at best would be an added complication exacting the best of workmanship with no possible gain in economy.

Having proceeded with the work to the time of application, everything should be carefully inspected to see that no dirt or chips have got into any of the teeth of the gears or around any of the bearings and interspaces. The lubricant, composed of about equal parts of a good machine oil and a solid grease, may now be put into the case through the hand inspection hole and should fill the case about half way, or to the shaft lines, although a half of this amount increased up to a two-thirds filling of the case is entirely permissible for good results.

To operate the change speed gear on the vehicle means are, of course, necessary for moving the shifter rod from the operator's seat. This is accomplished, preferably, through a side lever fulcrum shaft, radius levers, rods and connections terminating at the shifter rod of the change speed gear.

◆◆◆

Windmills for Driving Electric Generators.—An example of the use of the windmill for generating electricity is provided by the village of Askow, in Denmark. The windmill can be supplemented by a small oil engine in case of a period of quiet weather. There is storage capacity for four or five days, so the engine is seldom required—only about thirty days every year. From this station the village is supplied with light, and power is provided for industrial and agricultural purposes. Growing use is also being made of windmills in the West for generating electricity in connection with agriculture. The question of utilizing the wind for driving farm machines is of great importance to farmers in those regions, as there are no large streams for them to harness. Several windmills are worked together on some farms to operate the generators, and in this way 10 horsepower motors are working in the field continually.

TAKING UP LOST MOTION.

BY WALTER W. EDWARDS.

No matter how well built an engine may be, or how carefully run, it is sooner or later necessary to take up the wear at various bearings. The method of procedure necessarily varies, depending on the bearing to be adjusted, and also upon its size.

The object of taking up the wear on a bearing is to make it so tight that it will not pound, and yet sufficiently loose so that there is no undue friction to cause heat. Pounding and heating are the limits, so to speak, between which an engineer must work, and various expedients are used to determine, without actually running the engine, whether or not either limit has been exceeded.

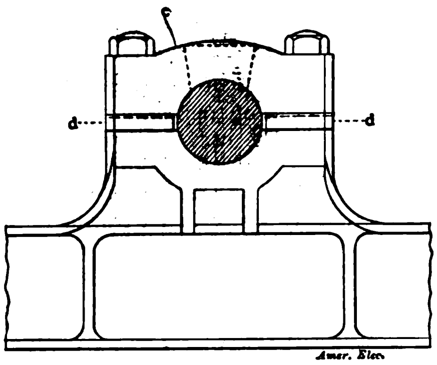

FIG. I.

One of the best methods of testing the adjustments of bearings is to take leads from it and measure their thickness after the cap of the bearing has been set up tight on the distance pieces and liners on either side. To apply this method to a bearing such as shown in Fig. 1, the cap *c* is removed, leaving the journal bare as shown in Fig. 2. Pieces of lead wire are then laid across the journal as shown at *aa* in Fig. 2. In choosing wire for this purpose, care should be exercised in obtaining lead which is quite soft. Wire that is made of pure lead is very good, as are also many grades of fuse wire used in electrical work. There are some grades of fuse wire, however, which are altogether too hard for the purpose, and these should be carefully avoided. The wire should be about No. 22 gauge, and at lease two pieces should be used, and sometimes three, if the bearing is a very large one. When these wires are laid across the bearing as shown in Fig. 2, the cap *c* should be replaced and the nuts on the studs set up as tightly as possible. In the close quarters usually found around engine bearings, it is best to use a wrench with a short handle, striking the handle of the wrench with a light sledge. When the nuts are set up as tightly as they will go, without using undue force on them, their positions should be marked lightly by means of a center punch so that it will be possible subsequently to return them to their positions.

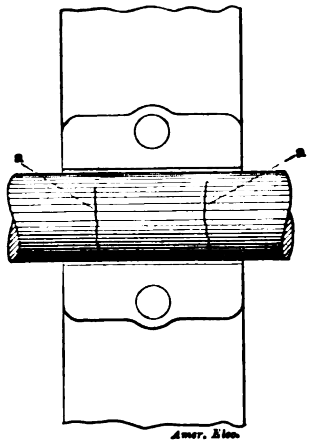

FIG. 2.

The nuts may then be unscrewed, the cap lifted off, and the wires removed. They will be found to be crushed into thin lead ribbons, the thickness of which is a measure of the amount of play between the journal and brass. The lead ribbons should be measured by means of a wire gauge. If the shaft is large, say 12 inches or more in diameter, and the engine does not run more than 120 revolutions per minute, the leads may have a thickness of 28 to 30 gauge. If the shaft is smaller and the number of revolutions greater, the thickness of the ribbons should not be less than 32, and may run as high as 34. The writer has taken leads of No. 35 gauge on bearings which had not given any trouble, but the practice is not recommended, especially on an engine with which the engineer is not thoroughly familiar.

The leads should be carefully examined, and the gauge tried at different points to determine whether or not they are of uniform thickness. If they are thicker near the ends than at the middle, it is evident that the brasses are not as close at the sides as they are at the bottom of the brasses. This is as it should be, since brasses that are close at the sides increase the friction without materially increasing the surface that is effective in transmitting energy. This point will be made clear by an inspection of Fig. 3. The direction of the application of force to the brass may be represented by the arrow. The effective area may be found by projecting the bearing surface in the line *ab*. If the rubbing surface of the brasses is cut away by an amount equal to one-quarter on each side, the friction has been reduced proportionately, and the effective area reduced from *ab* to *cd*. If the leads are thinner at the sides than in the middle, the babbitt or brass should be cut away at the sides. If the leads are uniformly too thick, a liner should be taken out at each side to allow the brasses to come closer together. These liners are always placed on top of the distance pieces *dd*, Fig. 1, for this purpose, and when all the liners have been removed through successive adjustments, the distance pieces should be planed thinner.

A word of caution is necessary in regard to this method and its application A bearing may give very good leads and the brasses still have high places between the leads, which cause heating at these points, although where the leads were placed the brasses were very accurately adjusted. Until an engineer has become thoroughly familiar with his engine and is reasonably sure that no high places exist, he should not take as thin leads as he might later. There is, perhaps, no other one thing about engine management that requires as much good judgment as the adjustment of bearings.

There are other methods by which brasses, such as crank-pin brasses or those on the wrist-pin, may be adjusted, but as they are comparatively simple, an extended description is not needed. One widely used method is to key the brasses on the pin as tightly as possible, and then loosen the key or nuts as the case may be, until sufficient lost motion is provided. The amount of looseness depends on the size and speed of the engine and also upon the taper of the gib and key, or the pitch of the threads on the bolts. This method depends for its success almost wholly on the experience and judgment of the engineer. It is also open to the objection that the loosening process may leave the liners between the brasses so loose that there is danger of their flying out when the engine is running. If dowel pins are fitted, they would, of course, prevent this.

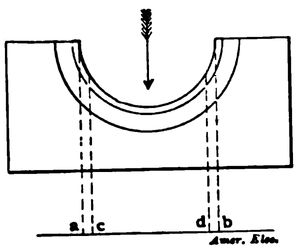

FIG. 3.

Another method of determining the amount of lost motion to be allowed in connecting-rod brasses is to set the brasses up as tightly as it seems probable that they will run, and then test the work by using a bar or other means of moving the end of the rod from side to side on the pin. In large engines there is always sufficient lateral motion possible to test the adjustment of the brasses. If they are moved with difficulty from side to side it is plain that they are set up too tightly, while on the other hand, if they are moved too easily, it is probable that they can stand more tightening. The great advantage that this method has is that it requires but little time to apply it.

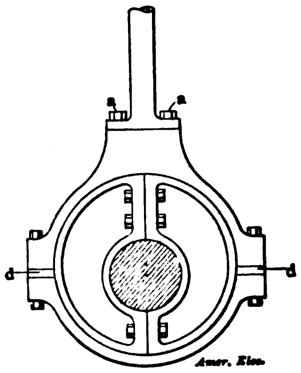

FIG. 4.

Other bearings often permit other methods of adjustment. In the case of an eccentric strap such as shown in Fig. 4, it is better to take up the lost motion by disconnecting the eccentric rod by the removal of the tap bolts *aa*. It is then possible to turn the eccentric strap by hand and if found too loose, the nuts at the side may be unscrewed and liners removed from the distance pieces *dd*. If there are no liners there, the distance pieces should be made thinner, and liners introduced. If there are no distance pieces the straps themselves must be cut away. The object of introducing distance pieces such as are shown by Fig. 4, is to facilitate this operation. The light distance pieces are easier handled in the machine shop than the whole strap.

In adjusting bearings by taking up the lost motion, care must be exercised not to change the length of any of the reciprocating parts. If, for instance, the wear in the connecting-rod brasses were continually taken up by the removal of liners, the length of the rod from center to center of the brasses would be shortened, and eventually the piston would strike the crank end of the cylinder. This can be guarded against by disconnecting at the crosshead, and then moving the piston as far as it will go in either direction. The extreme positions of the crosshead should be marked on the guides. These marks are called the striking points, and it should be the purpose of the engineer to keep the path of the crosshead as near central between these marks as possible. The length of the connecting-rod can be varied by putting liners back of the inner brasses at either end of the rod.

◆

CALIBRATION OF RECORDING WATTMETERS.

BY GEO. T. HANCHETT.

There is perhaps no electrical instrument over the accuracy of which controversy is as likely to arise as over that of the recording wattmeter. The principal reason for this is obvious: the inaccuracy of such a meter affects the pockets of all concerned. As a matter of fact, a recording wattmeter cannot be expected to register closer than 2 per cent except by great good fortune, and any controversy over a matter of that magnitude is an idle one for the reason that when the meter is checked again to verify statements, the result is likely to be as much in error on the other side of accuracy.

There are several convenient ways of testing a meter. The most primitive of these, but one of the most convenient, is to burn a known number of lamps for an hour, reading the meter before and after the test. The 3½-watt, 16-c.p. lamp consumes about 56 watts, and if ten lamps are burned for an hour the meter should indicate approximately 560 watt-hours. Any gross error, such as one of 30 or 40 per cent, can be detected in this way.

For closer work tests can be made in several different ways. These are divided into two classes. One is known as the revolution method and the other is the test by dial reading. The revolution method always involves the timing of the revolutions of the meter disc and the computation of the energy that is being recorded by the employment of suitable constants. The method of dial reading consists in passing through the meter a quantity of electrical power and comparing this measured quantity, multiplied by the time, with the indications of the dials. This is sometimes the only resource when the cover of the instrument cannot be removed and the revolving disc is not otherwise visible.

The usual plan in calibrating by dial indications is to run the meter under a suitable load, preferably about the average load that is used on the meter in practice, and to note the time required for the first dial hand to make one complete revolution. The electrical power is measured by a portable indicating meter inserted in circuit with the meter to be tested and read at five-minute intervals, the general average being taken, and the power thus measured being multiplied by the time. In alternating-current work the standard instrument should be a portable wattmeter, for in such cases the product of the ammeter and voltmeter readings will not be the true power.

Another method is to put in circuit with the recording wattmeter a second recording wattmeter of known accuracy and to allow them both to run for twenty-four hours. This makes a test on a complete cycle of loads and the readings of the two meters can be compared directly. The standard meter, however, requires constant attention and for close work should be calibrated before and after the test. It has the advantage that it measures true watts on an alternating-current circuit.

The revolution method is the one employed most frequently, and consists in measuring the power and simultaneously timing the revolutions of the disc. The power passing through the wattmeter is proportional to the speed of the disc and can be accurately represented by the speed of the disc multiplied by a certain number, which is called the disc constant. This constant varies with the different makes of meter because of the flexibility of the units that may be chosen. The general equation is

$$\textit{Kilowatts} = S\,K,$$

where S is the speed and K is a constant.

It is plain that if S is the speed in revolutions per minute, the constant will have one-sixtieth of the value that it would have if S were revolutions per second, and similarly, if the power were expressed in watts instead of kilowatts, this would increase the constant 1000-fold. A common form of constant, which is much used with Thomson recording wattmeters, is that number by which the revolutions made in one hour must be multiplied in order to give the watts passing through the instrument. In testing an instrument which has such a constant, it is usually most convenient to take the time that the disc requires to make ten revolutions, which can be done to within two-tenths of a second by means of a stop watch. Taking a practical case, suppose that an instrument has a calibrating constant of 2, and that the test load is such that the disc makes ten revolutions in 70 seconds. The power passing through the instrument is equal to

$$\frac{10 \times 3600 \times 2}{70} = 1028.6 \textit{ watts}.$$

This should be compared with the power measured simultaneously by accurately calibrated indicating instruments. If the computed power is greater than the measured power, the disc should be made to travel more slowly by adjusting its magnets, and conversely.

The constant of the meter should not be confused with the constant of the dial mechanism, which is usually printed thereon, and which may be a totally different figure, because of the gear ratio selected. When the first dial, indicating 1 kilowatt-hour per revolution, makes one turn to 1000 of the disc, then the constant of the meter is the same as the constant of the disc, but when the gear ratio differs from this a proportionate number is introduced which alters the constant of the meter. Thus, when a disc constant is 1.25 and the ratio between disc and dial motions is 1000, then the constant of the meter is also 1.25. If, however, it is desired to have the meter read directly, it will be necessary that the dial hand make one revolution to 800 of the disc, which could be done by selecting a proper gear ratio.

If the constant of the disc is not given, it is always possible to determine it by noting the ratio between the disc and the dial reading kilowatt-hours. The constant in this case is that number by which the revolutions per hour must be multiplied in order to give the power in watts. Assume 1 kilowatt to be flowing through the instrument. Then in one hour the kilowatt-hour hand should make one revolution, and the disc will make a certain number of revolutions, which, when multiplied by the constant, equals 1000. Consequently, the constant equals 1000 divided by the ratio between the rate of disc revolutions and that of the kilowatt-hour pointer; that is,

$$K = \frac{1000}{\textit{ratio}}.$$

Another way in which the constant may be expressed is as the time in which the disc will make as many revolutions as there are watts flowing through the instrument, as

$$\textit{watts} = S\,K,$$

where S is the revolutions per hour, then the time, t, in hours has the following relation to the constant, K:

$$t\,S = \textit{watts} = S\,K;$$

that is to say, $t = K$, so that in K hours the number of disc revolutions would equal the watts flowing through the instrument. It is sometimes convenient to reduce the time to seconds and the watts to kilowatts, when the relation becomes

$$t'' = 3.6\;K,$$

t'' being the time in seconds required for the disc revolutions to equal the kilowatts. Thus, if a meter had a disc constant of 2, it would in 7.2 seconds make as many revolutions as kilowatts, and if the disc constant were ½, it would do this in 1.8 seconds. In some cases it would be very inconvenient to time the disc for so short a period, so the constant is multiplied by 100 and the resulting revolutions are correspondingly divided. Thus the constants, 360 and 180, would indicate six and three minutes, respectively.

The errors to which a recording wattmeter may be subject are principally those of friction. There is, of course, a possibility of change in the magnetism of the retarding magnets or of the resistance of the potential circuit of the instrument, but these are insignificant compared with the friction error. The principal friction of the instrument is that of the commutator and brushes. Next to that comes the friction of the bearings, and lastly the friction of the recording mechanism. The latter is so small as to be practically negligible, and a recording wattmeter in good order will give substantially the same readings when tested by the rotation method whether the recording mechanism is in place or not. By far the most important item is the friction of the brushes, and its importance will readily be recognized when it is observed how the slightest tampering with them affects the accuracy of the instrument. Friction of the jewels is, like the friction of the mechanism, very small.

Because of the friction of the brushes, etc., when a meter is at rest a certain definite amount of current must flow through the series winding before it will start. This may be of such magnitude that at the full line voltage the starting power may amount to as much as 60 or 70 watts—ample for one 16-c.p. lamp. As soon as the meter is once started, the amount of current necessary to keep it in motion is considerably less, perhaps only one-half as much as the starting current. After the armature once starts, the retardation due to friction is roughly a constant quantity and on very light loads is a source of large percentage of error; on very heavy loads it is of less importance. It is a common plan to provide in such instruments an additional independent source of torque, which shall be constant and will balance the friction torque. This is done by inserting in series with the meter armature a field coil which is adjusted in its position with relation to the armature until sufficient torque is obtained to compensate for the retarding effect of friction. This is best obtained by adjusting the coil so that the armature will start on no load and then gradually moving the coil so as to reduce its influence on the armature until the disc stops.

It must not be forgotten that the torque due to the starting coil is proportional to the square of the applied voltage. If, for instance, an instrument were designed to work on a system of 110 volts, the torque of the starting coil would be proportional to the number 12,100. If the system were changed and the voltage raised to 120 volts, the torque would be proportional to the number 14,400, or 20 per cent greater than before. Therefore, it is very important that the meter be operated at the voltage for which it is intended.

The errors due to friction and due to the magnets are almost always such as to make the meter run slow. Artificially aged magnets frequently show a tendency to strengthen, and friction of any kind always increases with age. Hence, the usual trouble with the meter is that it records too little rather than too much.

In testing a meter for very close work, it is important to note whether the delivered watts or the supplied watts are compared with the recorded readings of the meter. In commercial work the meter is intended to record the delivered watt-hours. Hence, in connecting standard instruments to the meter circuit for the purpose of checking its record, the series or current connections, whether for an ammeter or a wattmeter, should be on the house side of the meter in order that the current of the potential coils of the meter may not be included in the reading of the delivered power. The voltmeter or potential connections should be made on the line side of the meter in order that the recording wattmeter may not measure the energy of the potential circuit, of which no account is taken by the calibrating instruments. The drop through the series coils of the meter is usually so small that it can be neglected.

In testing three-wire meters, several quite important precautions should be taken. The meter is supposed to be correct on a balanced load. If the load becomes unbalanced, the magnetic effect of the field upon the armature is not so effective as if it were balanced, and the meter runs slow. One expedient is to balance the load accurately and remove the neutral fuse, in which case the meter is tested as an ordinary 220-volt, two-wire meter. This is not always a safe procedure, because, unless the system is under absolute control, some one is likely to upset the balance during the test and endanger the lamps.

Another plan is to install two shunts, one in each leg of the three-wire system, and transfer a millivoltmeter from side to side, or, better still, to have two millivoltmeters. A convenient blank form for testing meters by the dial method is as appears below:

Date..................

Test of meter located at John Jones', No. 10 Gamewell St.

Meter Data From Name Plate.

Type M. Volts, 240. Amperes, 15. Three-wire. Constant, 2. Manufacturer's No., 102,571. Company's No., 3,279. Measures electricity for —— Lights.

Corrected	averages	119.2	10.54	119.2	12.93

Watts+ $119.2 \times 10.54 = 1256$

Watts— $119.2 \times 12.93 = 1542$

Total watts 2798

Elapsed time 50 minutes

Kw.-hrs. by instrument $= \dfrac{2798 \times 50}{60 \times 1000} = 2.332$

Kw.-hrs. by meter $1.100 \times 2 = 2.200$

Percentage of accuracy $= \dfrac{2.200}{2.332} \times 100 = 94.3$

Error 5.7% slow

For a disc test the following form may be advantageously used:

Date..................

Test of meter located at 10 Gamewell St.

Meter Data from Name Plate.

Type M. Volts, 240. Amperes, 15. Two wire. Constant, 1. Manufacturer's No., 21,749. Company's No., 1,273. Measures power to — pump. Disc constant, 1.25.

Results of Test.

Time of 10 revolutions 63 seconds

Volts 240 Corrected, 239

Amperes 2.9 Corrected, 2.85

Watts by standard instruments 682

Watts by meter $\dfrac{3600 \times 1.25 \times 10}{63} = 715.0$

Percentage of accuracy $\dfrac{715}{682} \times 100 = 104.8$

Error 4.8% fast

It may be well to add in closing that meter testing is always a matter over which controversy is likely to arise, perhaps lawsuits, and consequently any one who tests meters should be very sure of the accuracy of his instruments, calibrating them both before and after the test.

◆ ◆ ◆

FIRE ALARM CIRCUITS.

BY SIDNEY DIAMANT.

As in all cases which involve distribution of circuits over an extensive area, the circuits, etc., in a fire alarm system are controlled fundamentally from a main or central station. Fig. 1 is a general plan for two complete sets of circuits, showing the central station, fire houses and fire alarm boxes. In a large city wherein congested districts necessitate the prompt sending of an alarm, there may be hundreds of such circuits. The cycle of operation of the fire alarm circuits and the manner of immediately having the apparatus dispatched to the scene of fire is explained by aid of the general plan and three detailed diagrams.

The fire alarm is turned in by means of a fire box, the circuits of which are represented in Fig. 2. The small T handle which appears on the outside of the box is turned to the right and at the same time pulled toward the operator so as to force open the outer door when the latch is released by the turning mechanism. The turning of this handle is accompanied by the loud ringing of a bell which in no way has any connection with the alarm circuit, but is merely intended to frighten off a meddler. While this may generally be regarded as an advantage, yet trouble often arises due to the frequent misinterpretation by ignorant persons of this bell for the main alarm; and so the signal does not reach the central station. However, a fairly intelligent person who assumes the responsibility of turning in an alarm, will read on the inner door of the box, "Pull down lever and let go." When the hand lever, shown in Fig. 2, is pulled down against the action of the actuating spring, the rack is lifted upward. During this movement of the rack, there is no contact between it and the large pinion, but when the hand lever is released, the actuating spring sets the mechanism in operation by engagement between the large pinion and the rack during the descent of the latter, properly guided. Because of the ratio between the diameters of the two pinions, the smaller one makes four revolutions during the complete travel of the rack. Therefore the star wheel to which the small pinion is rigidly connected, sends in four complete and identical alarms.

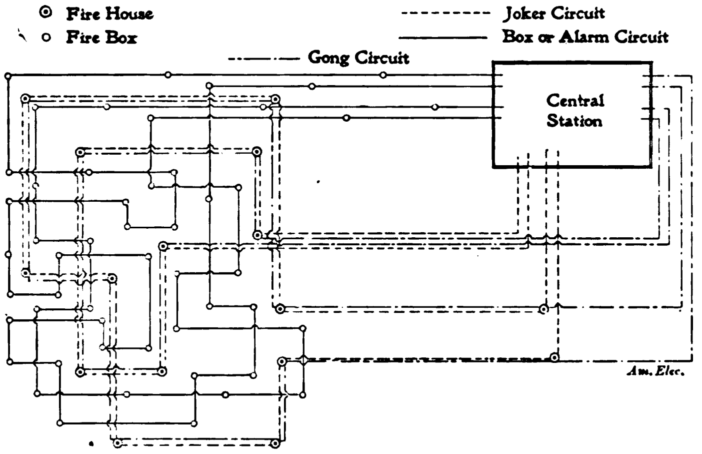

FIG. 1.—PLAN FOR TWO SETS OF CIRCUITS.

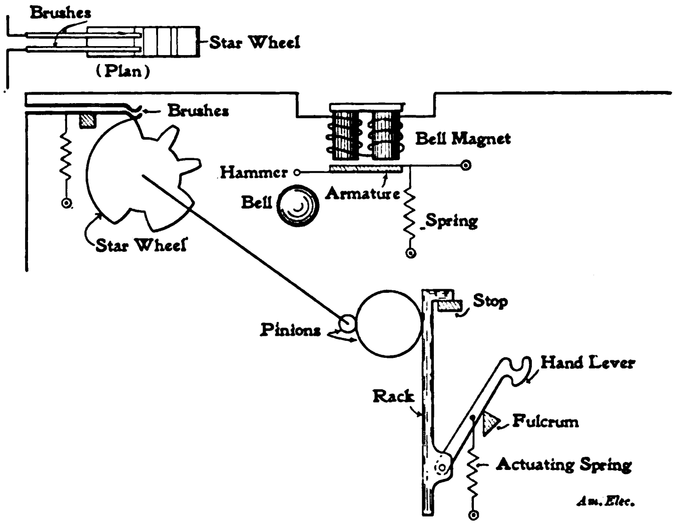

FIG. 2.—FIRE BOX CONNECTIONS.

Under normal conditions, when the circuits are not in operation, the two brushes touch the metallic star wheel, thus permitting the current, which is comparatively small, to flow continuously. An insulating stop acts as a rest for the brushes when they are not in contact with the star wheel, but over a space between the teeth. During the transmission of the alarm the star wheel rotates in a direction such that the spaces between the teeth indicate the number of the call by successively coming under the brush ends. When the brush ends are over a space, the current is interrupted and the bell magnet, which is in series with the line, is de-energized, allowing the spring to pull the hammer against the small bell. Under normal or "no alarm" conditions, the elastic force of the spring is overcome by the magnet which is then energized by the current flowing through its windings. Thus each time the ends of the brush are opposite a gap between the teeth of the star wheel, the hammer strikes the bell once. The star wheel in the diagram has three indentations at equal intervals separated by short periods of contact, then a longer period of brush contact, then a single indentation or space, followed by a long period of contact, before the alarm is repeated. This star wheel put into operation would result in the transmission of four alarms corresponding to box 31. As the sender hears the alarm being rung off at the box, the central station is simultaneously receiving the signal.

Fig. 3 illustrates diagrammatically the arrangement of circuits at the central station. During each interruption of the main circuit, previously considered, the relay magnet *RM* loses its magnetism and the armature is drawn by a spring against the contact *C*, closing the local battery circuit. Each time this local circuit is closed, the bell *B* receives an impulse and at the same time the recorder magnet *Rc M* records the alarm either by punching holes in the tape *T*, or by means of a stylus recording with ink. In either case the record is effected mechanically by the appropriate movement of an arm attached to the armature of the recording magnet *Rc M*. As soon as the first round of the alarm is received, it is sent out on the "joker" circuits to every fire house and to the Board of Fire Underwriters by the person to whom this duty is assigned. Upon proper assurance of the accuracy of the alarm by the receipt of three or four rounds, the signal is sent out on such gong circuits as will result in the most prompt response from the fire house nearest the location of the fire.

The operation of the gong alarm is accomplished by a suitable star wheel, shown in Fig. 3, which depends for its action upon mechanism similar to that in the fire box already described. At the central station there is systemmatically arranged on boards a number of these star wheels, each one of which is intended to duplicate the alarm received from a particular fire box. Fig. 4 illustrates the general arrangements by means of which the alarm is received at the fire house. The joker bells are operated on an open circuit system so that the depression of the sending key by the operator energizes the joker magnet *JM*. Its armature is attracted against the force of the spring and the hammer strikes the bell. This signal is intended only for the man at the desk, as it would not be judicious to awaken the firemen in the night if their services were not immediately necessitated by the existence of a nearby fire; the joker bell and magnet, therefore, are relatively small.

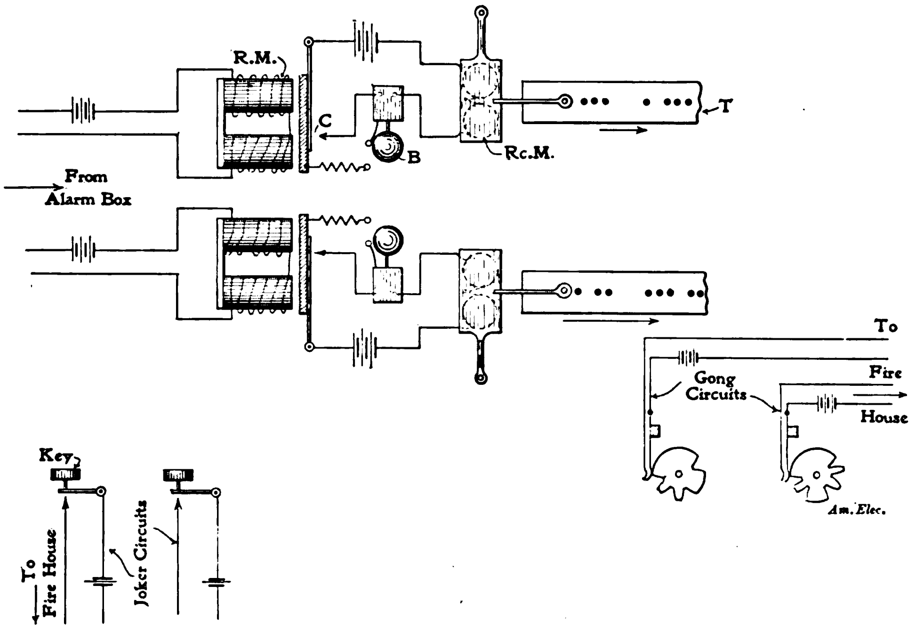

FIG. 3.—CENTRAL STATION CIRCUITS.

When the desk man at the fire house receives this signal he records it, and if it does not correspond to a box in the district no further attention is given to the matter, except that the horses, which by this time have taken their positions under the harness drops, are sent back to their stalls. If, however, the alarm is from a box in the district, the desk man gives the signal arousing his men. The apparatus is in readiness, and after assurance by a few rounds of the alarm on the joker circuit, the crew and apparatus leave for the fire. Only in event of a confusion of the joker signal does the crew wait for the gong alarm, which, in the case of good condition of the circuits, is generally heard at the fire house either concurrent with the departure of the apparatus or soon after. The gong circuit is operated by the star wheel at the central station exactly as the receiving apparatus there is operated by the star wheel in the fire alarm box. The gong gives a very loud alarm.

In case of the existence of a fire which promises to cause more than ordinary damage if not properly checked, special telephonic orders are given to have the apparatus advanced from one fire house to the other toward the fire, so that when a second alarm is given, the fire house nearest the fire always has apparatus for immediate response. In this way apparatus several miles away from the fire is gradually moved toward it, the advance depending upon the number of alarms given, so that there is centered about the troubled district sufficient means to promptly meet the demand for additional service.

As the diagrams clearly show, the primary operation of the alarm system is on the closed circuit plan, while the secondary or signal part of the cycle is through local circuits normally open and controlled by relay magnets in the main line. The most important advantage afforded by this method is the promptness with which trouble in the circuits makes itself apparent. If a break occurs on the line, the local circuit at the central station is closed by this interruption, causing the small bell *B* (Fig. 3) to ring continuously, calling attention to the circuit that is out of order. In case of a dead ground, the greater part of the current flows through the earth so that the current in the main line is considerably weakened; as in the case of an open circuit, the relay magnet at the central station closes the local circuit, indicating trouble by continuous ringing of the bell *B*. If, however, there exists only slight or temporary trouble which is not sufficient to disturb the operation of the system, the main magnets are not sufficiently demagnetized to allow notice to be given at the central station. So long as the system is not rendered inoperative no trouble is announced. Another advantage of the closed circuit system is that it does not depend upon large current strength for its operation, but upon the interruption of a comparatively small current. This advantage should offset the slight disadvantage of continuously using the current under "no alarm" conditions. Moreover, the current is so very small that the expense for its maintenance is not important.

In some cities the manual method of operating the joker and gong circuits is replaced by automatic machinery. A non-interference feature is also introduced which prevents the confusion of two alarms which were sent almost simultaneously from different boxes. The arrangement allows that box which first received the impulse to send in its complete alarm to the central station, after which the box next put into operation sends in its alarm.

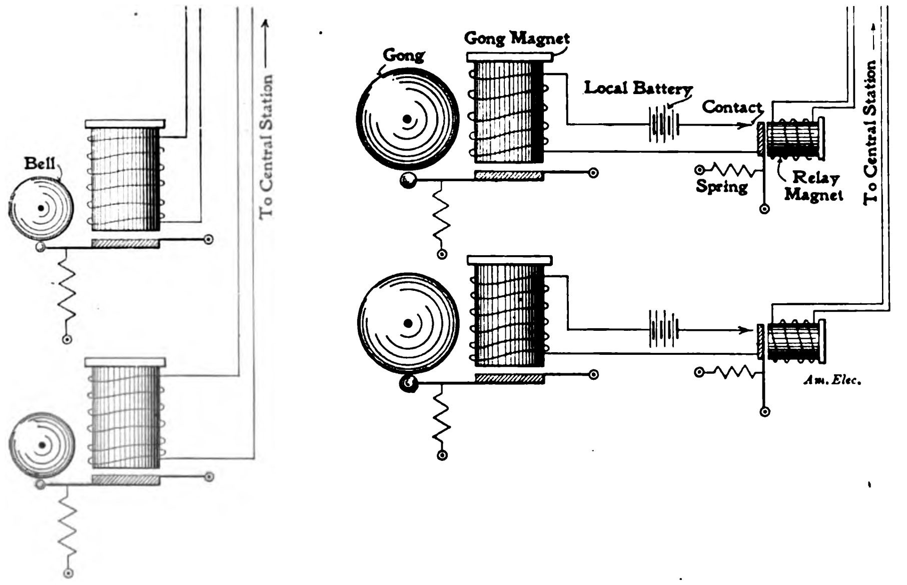

FIG. 4.—FIRE HOUSE CIRCUITS.

◆◆◆

SOME PRACTICAL POINTS FOR CENTRAL STATIONS.

One of the questions most frequently asked by those interested in the layout of central stations of moderate size is, "Which type of boiler is best suited to small stations, the water-tube or the ordinary horizontal return tubular boiler?" This question, as applied to a station of about 250 horse-power equipment, is answered in the Question Box of the National Electric Light Association in favor of the shell boiler by eleven practical electric light men and in favor of the water-tube boiler by eight others. The preponderance is obviously on the side of the shell boiler, and as the eleven advocates of it (for this size of plant) include some of the most prominent engineers in this line of work, it is fair to assume that the builder of a small station would do well to pin his faith to the old return-tubular shell type.

Another interesting topic is the relation between the boiler capacity of a station and its peak load. According to all but one of the opinions on this subject expressed in the Question Box, it is cheaper to operate a boiler plant of a capacity sufficient only for the average load and to use forced draft during the peak load than it is to use boilers of an aggregate capacity equal to the maximum peak load. The costs referred to are those of fuel and operation, presumably including depreciation and repairs.

As to the relative merits of the lever and pop safety valves, nine authorities declare in favor of the pop valve, while one points out that in a salty atmosphere the spring of the pop safety valve is likely to become weakened by rust. Gradually tightening the spring, he states, contracts the area of the relief passage, so that the valve may become dangerous in time.

The preference for 250-volt machines and auxiliary means for balancing a three-wire system, instead of 125-volt machines on each side of the neutral, which has several times been expressed in the editorial columns of this paper, is shared by all of those who have presented opinions on the subject in the Question Box, excepting one or two who entertain the erroneous idea that the large Edison stations use dynamos of half voltage to the exclusion of dynamos of overall voltage with balancers. In point of fact, the large Edison stations which have been built in recent years use either the latter arrangement or its equivalent, consisting of 250-volt rotary converters with compensating coils or a neutral connection tapped into the middle of the converter transformer windings.

Shunt-wound dynamos have been found preferable to compound-wound machines for lighting stations because of the greater simplicity of connection, ease of paralleling and dividing the load, and greater freedom from accidents due to "motoring." In railway or other stations where the load fluctuates violently and frequently, compound-wound machines are preferable because hand regulation is impractical.

In discussing the operation of compound-wound dynamos in parallel, several contributors to the Question Box have fallen into the common error of supposing that the compounding of each machine can be adjusted by means of a shunt strip across the terminals of its series field winding. Only three writers offered the correct advice to the effect that the compounding of each machine can be adjusted individually only by means of a resistance *in series* with its series field winding. When compound-wound dynamos are connected in parallel, all of the series windings are in parallel between the equalizer bus-bar and one of the main bus-bars; consequently a shunt strip in parallel with one of the windings is in parallel with all of them and affects all of them.

Babbitt Metal for Motor Bearings.—The manager of a prominent interurban railway is using the following formula for making babbitt metal for motor bearings and states that it has given better results on heavy high-speed service than any other he has ever tried. The composition consists of forty-eight pounds of tin, four pounds of copper and one pound of antimony. The copper and tin are melted first and the antimony added afterward.

Lessons in Practical Electricity

TRANSFORMER LOSSES AND REGULATION.

As stated in last month's lesson, the ratio between the applied primary e.m.f. and the secondary terminal e.m.f. of a transformer is not always equal to the ratio of primary to secondary turns of wire around the core. When a load is put on the secondary circuit, the flow of current through the secondary winding tends to demagnetize the core, since it flows around the core in the contrary direction to that of the primary current. It does not demagnetize the core, however, because it is not in phase with the magnetizing current in the primary winding. But it shifts the phase of the primary induced e.m.f. so that it is less directly opposed to the applied e.m.f. and therefore allows more current to flow in the primary winding than when the secondary circuit was open. The result of this action is to produce changes in the primary current corresponding approximately to the changes in the secondary current, thereby making the transformer practically self-regulating when the primary is connected to a constant-potential circuit. The regulation cannot be perfect, however, on account of the internal losses. If the potential at the primary terminals be kept absolutely constant, the e.m.f. at the secondary terminals will be appreciably less when the secondary is fully loaded than when it is open; the difference is termed the "regulation" of the transformer. Thus, if the no-load secondary e.m.f. is 103 volts and the full-load e.m.f. 100 volts, there is a drop of 3 volts, and the regulation is 3 per cent (3 × 100 ÷ 100).

This difference of 3 per cent is caused by the drop in volts in the windings due to their resistance, the opposing effect of e.m.f.'s induced in the two windings by magnetic flux which leaks around between the windings instead of embracing both of them, and losses in the core which demand a certain amount of current in addition to that which is useful in the secondary circuit.

There are two classes of core losses: the loss by hysteresis or the tendency of the iron* to resist changes of magnetic condition, and the loss due to currents induced in the core by the alternating magnetic flux, and known as "eddy" currents. The loss by eddy currents is reduced to a relatively small proportion of the total losses by making the core of thin strips of metal instead of a solid block, and coating each strip with an insulating varnish so that the eddy currents cannot easily flow from plate to plate of the core. The benefit of thus dividing the core will be evident when it is considered that the eddy current loss is proportional to the *square* of the thickness of the core plates or strips.

The loss by hysteresis, according to Mr. C. P. Steinmetz, is proportional to the 1.6th power of the maximum magnetic density in the core. Thus, representing the maximum number of magnetic lines per square inch of core cross-section by B, the number of cycles per second by f, and the cubic inches of iron* in the core by v, the watts lost by hysteresis will be practically equal to

$$P_h = \frac{25\, B^{1.6}\, f\, v}{10{,}000{,}000{,}000}.$$

The thickness of the core strips does not affect this loss. The loss by eddy currents is practically equal to

$$P_e = \frac{43\, t^2\, f^2\, B^2\, v}{10{,}000{,}000{,}000},$$

so that the total core losses in watts are practically

$$P_c = \frac{v\,(25\, B^{1.6}\, f + 43\, B^2\, t^2\, f^2)}{10{,}000{,}000{,}000}.$$

Thus, with a maximum density of 40,000 lines per square inch, core strip of good quality 0.01 inch thick, and a frequency of 60 cycles per second, the core losses would be about 0.024 watt per cubic inch of core.

If the primary winding of a transformer be connected to a supply circuit of proper voltage and frequency and the secondary circuit be left open, a small current will flow in the primary. This is the "exciting" current, and consists of two components which are exactly one-quarter of a cycle displaced from each other in phase relation. One component, termed the magnetizing current, produces the magnetic flux in the core; the other is absorbed by the core losses just mentioned. The magnetizing current, which may be represented by I_m, is equal to

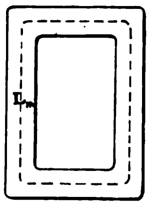

FIG. 1.

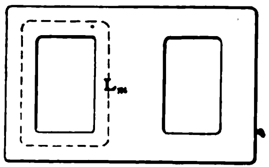

Amer. Elec.

FIG. 2.

$$\frac{k_m\, L_m}{N_t} = I_m,$$

in which k_m is the number of ampere-turns per inch of core length, L , that are required to produce 0.707 of the maximum magnetic density in the core. (The *effective* magnetic density = 0.707 × maximum density, and requires the same ampere-turns as a steady density equal to the effective density.) N_t is the number of turns of wire in the whole primary winding. The dotted lines in Figs. 1 and 2 indicate what is meant by the core length.

The core-loss current is equal to the core loss in watts divided by the primary induced e.m.f., with which it is exactly in phase. The induced e.m.f. is

$$E_i = 4.443\, \Phi\, N_t\, f \div 100{,}000{,}000,$$

Φ being the effective magnetic flux in the core, and f the cycles per second. The effective flux is equal to 0.707 × the maximum flux, and the maximum flux is equal to the maximum density multiplied by the core cross-section. Consequently,

$$E_i = 3.1416\, B\, A\, N_t\, f \div 100{,}000{,}000.$$

Dividing the watts of core loss by this gives the core-loss current, thus:

$$\frac{P_c}{E_i} = \frac{L_m\,(1.7\, t^2\, f\, B + B^{0.6})}{12.57\, N_t} = I_c$$

Since the core-loss current and the magnetizing current are one-quarter of a cycle apart in phase, the relation between them and the exciting or no-load primary current is the same as that between resistance, reactance and impedance; thus:

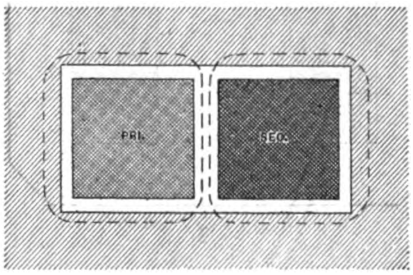

FIG. 3.

$$I_o = \sqrt{I_m^2 + I_c^2}.$$

The magnetizing current is usually much greater than the core-loss current, and since it is one-quarter of a cycle behind the primary induced e.m.f. in phase, the exciting current lags behind the induced e.m.f. almost a quarter of a cycle. The volts lost by the passage of this current through the primary winding, therefore, are not directly opposed to the applied e.m.f., and do not affect the regulation of the transformer very greatly.

Magnetic leakage may affect the regulation considerably. This leakage consists of magnetic lines which pass between the two windings, instead of encircling both of them, as indicated by the dotted lines in Fig. 3. The amount of leakage depends largely upon the type of transformer core and arrangement of the windings. There

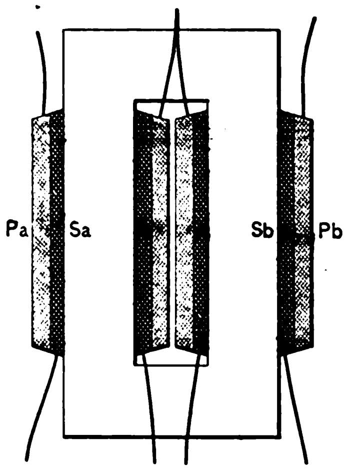

FIG. 4.

---

*The material used in transformer cores is really annealed sheet steel.

are two general types of core; these are shown in Figs. 4 and 5. In the first type, the windings are divided into two sections, one located on each "leg" of the core; in Fig. 4 the primary sections are indicated by P_a and P_b, and the secondary sections by S_a and S_b. As this diagram indicates, the primary winding is usually put outside the secondary; the principal reason for this arrangement is that the voltage of the primary winding is very high and the winding requires to be more heavily insulated than the secondary.

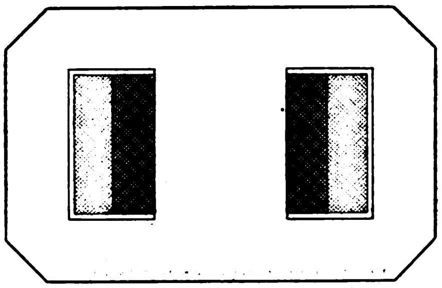

FIG. 5.

Transformers of the type represented in Fig. 5 are known as "shell" type. When the windings are arranged one over the other, the primary is on the outside, as in the case of the other type of core. Except when it is of importance to get as much radiating surface as possible for the secondary winding, this arrangement is preferable to the side-by-side arrangement indicated in Fig. 6 because it makes the leakage path between the windings longer than the latter disposition of coils. Comparing Figs. 5 and 6, for example, it will be found that the "seam" between the coils is nearly twice as long in the former as in the latter case, although the core holes or "windows" containing the coils are the same size in both. This longer seam reduces the leakage flux because the reluctance of the leakage path is greater.

The leakage flux induces in each winding a reactive e.m.f. which, while it is not squarely opposed to the active e.m.f.'s, does increase the drop in the windings and thereby impair the regulation. The drop in the windings due to their resistance usually affects the regulation more than any other one contributing effect, but the combined effects of core loss, magnetizing-current drop and magnetic leakage frequently equal the effect of resistance drop, and when the load is inductive, they may exceed it considerably, making the total drop much more than double the resistance drop alone.

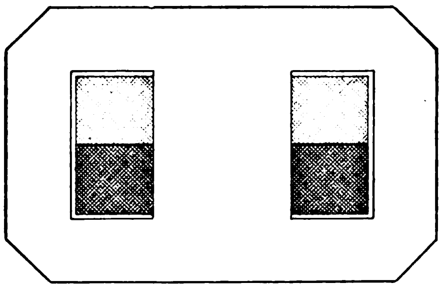

FIG. 6.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Flashing-Over of Rotary Converters.

To the Editor, American Electrician:

I should like to have some of your readers who are familiar with the operation of rotary converters inform me why these machines flash over at the direct-current end, and what the remedy is for that trouble. I am familiar with the care and operation of electrical machinery in general, and am alive to the necessity of keeping the commutator and brushes of any commutating machine clean and in good condition. This, however, does not seem to prevent flashing over.

Greenacres, Wash. B. E. Jerome.

Mr. Maloney's Commutator Trouble.

To the Editor, American Electrician:

I have been troubled with blackening of the commutator similar to that which troubles Mr. Maloney, and it is barely possible that the cause is the same. I am operating one 500-volt machine and one 110-volt machine, both direct-connected to their engines. When either of them becomes overloaded, the commutator blackens, and always at the same place relative to the engine crank position; the segments under the brushes when the engine is at the point of cut-off are the ones that blacken. I doubt if a direct-current dynamo direct-connected to a single-crank engine can be prevented from showing this trouble, which seems to be due to the vibration occurring at the cut-off position of the piston and crank.

Springfield, Mass. C. F. Barden.

To the Editor, American Electrician:

Referring to Mr. Maloney's commutator trouble, described by him in the July number of your paper, I would suggest that it may be due to grounds in the armature and in the main current outside the machine which cause heavy currents to pass the brushes and burn the segments under them when the armature is in the position giving maximum difference of potential between the armature grounds and those outside. This may be verified or disproved by carefully clearing the external circuits of all leaks, or disconnecting the machine from the switchboard and running it on an artificial load connected directly to the terminals and absolutely free from grounds. Systematic and rigid testing will certainly reveal the cause, and that is perhaps the best course to pursue.

The trouble may also be due to unstable contact by the affected brushes, resulting from eccentric motion of the commutator. The effect on the commutator is greatest at the positive brushes because the current passes from the commutator to these brushes and the damage done by an arc is worse at the positive side of the interrupted circuit; at the negative brushes, the brush faces suffer more than the commutator.

Henry Mulford.

Patchogue, L. I., N. Y.

To the Editor, American Electrician:

The trouble described by Mr. Maloney in the July number of the American Electrician is probably due to a lump in his belt, such as a thick place where the belt is spliced. Or if the pulley is covered to prevent slipping, there may be a high spot in the covering which causes the armature to jump when it comes under the belt. If the dynamo is direct-connected to its engine the trouble may be caused by vibration due to lost motion in the cross-head or crank-pin boxes. The fact that the machine is on the positive side of the system would, of course, not affect it, so far as the foregoing causes are concerned.

Brooklyn, N. Y. Herbert B. Brand.

To the Editor, American Electrician:

I have had the same trouble that Mr. Maloney describes in your last issue, caused from a "flat" in the commutator surface, and I cannot think of anything else that could cause it. If his commutator contains any low bars or flats, or is out of true in any respect, I would suggest that it be turned down as soon as possible; in the meantime, the commutator should be kept clean by sandpapering. Sandpapering will not remedy the trouble, however, because the sandpaper cuts the low bars as well as the others.

Des Moines, Iowa. Joe Fager.

To the Editor, American Electrician:

Mr. Maloney's commutator trouble is probably due to flat spots on the commutator surface. Sandpapering will not help matters permanently; the only cure is to turn the commutator true.

Newark, N. J. James J. Fox.

To the Editor, American Electrician:

Mr. Maloney's commutator trouble is very easily remedied. The segments that blacken have become flattened, and cannot be made right by sandpapering. The commutator should be turned off perfectly true.

R. G. Kausch.

To the Editor, American Electrician:

Mr. Maloney's commutator trouble, described in the last number of your paper, may be due to any one of several causes or a combination of them. If there is any source of regularly recurring vibration, this may cause the brushes to bounce a minute distance away from the commutator surface. If the commutator was not thoroughly baked out when the machine was built, the insulation may have shrunk, leaving the segments insecurely held; the result of this is that some bars have been jarred below the circular outline of the commutator and the brushes bounce and chatter when they strike these bars. The commutator should be carefully examined for this trouble, and if it exists the heads should be drawn home tight, little by little, tapping the bars all around during the tightening process; when the bolts cannot be tightened further without endangering their threads, the commutator should be turned down.

Brooklyn, N. Y. Geo. W. Malcolm.

To the Editor, American Electrician:

Referring to Mr. Maloney's commutator trouble, I would suggest that sparking and blackening of the commutator are caused by unsymmetrical positions of the brushes, untrue commutator surface, excessive vibration and other causes. Evidently, Mr. Maloney's commutator needs truing up, because the blackening always occurs at the same place.

Ladonia, Texas. Wilson A. McCown.

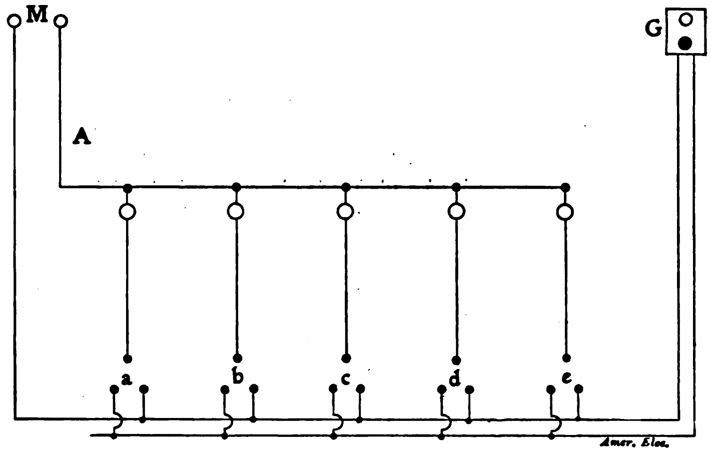

FIG. 1.—MR. MALCOLM'S SOLUTION.

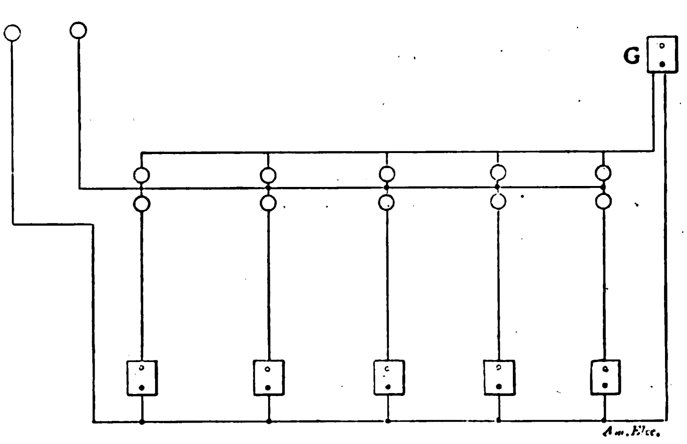

FIG. 2.—MR. SALTER'S SOLUTION.

To the Editor, American Electrician:

Referring to the commutator trouble experienced by Mr. V. P. Maloney, as described in the July number of the paper, I have often been able to correct such troubles in the commutators of street railway dynamos by merely resoldering the leads in the commutator lugs. The leads may be apparently secure in the ends of the bars, but resoldering may show that they were not, and may correct his trouble as it frequently has mine.

Cleveland, Ohio. Arthur B. Weeks.

Mr. Laughlin's Problem in Switch Connections.

To the Editor, American Electrician:

The accompanying diagram (Fig. 1) is submitted as a solution of Mr. Laughlin's problem, published last month. The individual switches are of the three-point or single-pole, two-way type and the gang switch is a single-pole affair connected so as to consolidate the two alternate points of all the individual switches. As long as the gang switch is open, the outlets may be controlled separately by the individual switches, but when the gang switch is closed, all of the outlets are connected to the supply circuit regardless of the positions of the individual switches. The latter, of course, are of the type that must always be on one or the other of the alternate contacts; that is, the mechanism must not be able to remain stationary in a mid-position, leaving the switch open-circuited.

This accomplishes what I infer to be Mr. Laughlin's purpose; namely, the *lighting* of all the lamps by the gang switch, irrespective of the individual switches. If it be desired also to extinguish all the lamps by means of the gang switch, irrespective of the others, then two switches must be used at *G*, one connected as shown and the other inserted in the line *A*, between the outlets and the supply circuit; with this second switch open, all of the lights will be extinguished; with it closed, the conditions would be exactly as in the case shown by the diagram.

Brooklyn, N. Y. Geo. W. Malcolm.

[Solutions exactly corresponding to Mr. Malcolm's diagram have been received from Jas. B. Dillon, Louisville, Ky.; Carl W. Littler, Swissvale, Pa.; E. C. McLean, New York; Wm. Merrill, Wilmington, Del.; Rene Moncel, Montreal, Canada, and G. S. Partlow, Essex Junction, Vt. None of them, however, included the alternative arrangement for extinguishing as well as lighting all of the lamps regardless of the individual switches.—Editor.]

To the Editor, American Electrician:

I enclose a diagram of connections (Fig. 2) as a solution of Mr. Laughlin's problem as stated in last month's number of your paper. My solution consists of providing two sets of lamps at the outlets, one set being controlled by the individual switches and the other by the gang switch *G*. I have used this arrangement for just such a purpose as he intimates. As he did not state that only one lamp is to be supplied from each outlet, I assume that there may be more than one, in which case this solution would be practical.

Maplewood, N. J. Ralph E. Salter.

Mr. Clark's Voltage Effect.

To the Editor, American Electrician:

The unusual voltage effect described by Mr. Clark in your last number is due to the fact that when the load is unbalanced to or beyond a certain extent the drop in the neutral wire is excessive and that wire therefore fails to equalize the voltage at the distribution centre. For example, if the load be such that the drop in the positive main is 6 volts, that in the neutral 4 volts and that in the negative main 2 volts, with the positive dynamo adjusted to give 110 volts at the lamps the voltage between the neutral and the negative main at the end of the feeder will be higher than that of the negative dynamo, no matter what the adjustment of the latter may be, within ordinary limits. Thus, in order to bring the lamp voltage down to 110 on the negative side, the dynamo on that side must be reduced to 108 volts, while if it be adjusted for 120 volts, like its mate, the voltage at the end of its side of the feeder will be 122.

The difference between the voltage at the lamps on the lightly-loaded side and the e.m.f. of the dynamo on that side, in any three-wire system, will always be equal to the difference between the drop in the neutral wire and the drop in the lightly-loaded main, and of the same character; that is, the lamp voltage is more or less than the dynamo voltage according as the neutral drop is more or less than the drop in the lighter main. When the drop in the neutral is the same as the drop in the lightly-loaded main, the voltage at the smaller load will be equal to that of the lightly-loaded dynamo.

Brooklyn, N. Y. Geo. W. Malcolm.

[Substantially the same explanation, without the statement of principle contained in the last paragraph, has been received from W. H. Freedman, Burlington, Vt., Henry Mulford, Patchogue, L. I., N. Y.; S. Von Prusinowski, Chicago, Ill., and O. Williamson, New York.—Editor.]

Queries and Answers

IMPORTANT.—No attention will be given to any inquiry which does not give the full name and address of the inquirer.

How does alternating current pass through a tin-foil condenser, and why will not direct current pass through it? J. H. G.

The condenser is fully explained in the Lessons Department of the April, 1904, number.

Where can I get the motor castings and transmission gear of the automobile desvribed in the July number? M. B. W.

So far as we know you cannot buy them ready-made; our "how-to-make" articles are not intended to advertise apparatus that can be bought on open market, but to enable those interested to build the apparatus.

Why is a recording watt-meter called an "integrating" meter? C. S.

Because it integrates the time-power load. That is, it measures the power during each small interval of time, multiplies it by that minute interval and adds up all of the products of time and power; this process is called "integration."

How can I rewind a 2000-volt 125-cycle transformer for 500 volts and 25 cycles? The secondary voltage to remain unchanged. C. W. G.

Use wire three gauge numbers larger than the present primary wire and put in as many turns as possible up to the same number that is now in the primary winding. Leave the secondary winding as it is.

I have a direct-current fan motor that I wish to use on an alternating-current circuit of the same voltage as the motor; how can it be changed to work on that circuit? M. C. A.

It cannot be changed so as to work satisfactorily on the alternating-current circuit. Exchange it for an alternating-current fan motor.

A constant-potential dynamo runs as a motor when connected to a suitable source, but will not generate when driven by an engine. It is a compound-wound machine of 6.6 kilowatts output. What is the trouble? F. G. K.

You ran it in the wrong direction as a dynamo or at too low a speed. The residual magnetism is evidently low and the machine requires at least full speed to "pick up." It should run in the same direction as a dynamo that it did as a motor.

What is the best packing for the cylinder head of a gasoline engine? (2) What causes explosions in the exhaust pipe of such an engine? (3) How can exhaust pipe explosions be prevented? A. C.

A ground joint. (2) The passage through the cylinder of a charge without being ignited. Failure to ignite may be due to too poor a mixture or defective igniting gear. (3) That depends on the exact cause of the failure to ignite; no general rule can be given.

How large a spark coil should be used for wireless telegraphy over a distance of three miles? (2) Can a telegraph circuit be operated over a metallic telephone circuit without interfering with the clearness of speech? (3) Why does a hand-power plating dynamo fail to generate? G. C. T.

Not less than a 3-inch spark. (2) Yes; it is done every day. (3) Because it is out of order. If you can furnish some definite information as to its condition, a more definite reply can be given. A list of possible causes a column long could be cited.

Please define "phase" and "cycle." (2) Is there any relation between them? D. F. D.

When two alternating currents reverse at the same rate but at different instants, they are "out of phase" with each other; if they reverse exactly together, they are "in phase." A cycle is one complete reversal of current or e.m.f. Thus, when a current starts from zero, rises to maximum in one direction, falls back to zero, rises to maximum in the opposite direction and again falls to zero, it has passed through one "cycle." (2) No.

How thick should the armature discs be in the 75-light dynamo described in the January, 1901, number of the American Electrician? (2) Should the discs be insulated from each other? (3) How can the 41 coils be put in 40 slots? (4) Do the slots run parallel to the shaft? (5) What is the formula for the horse-power required to drive a dynamo at a given load? E. W. P.

Not more than 25 mils. (2) Yes; varnish one side of each disc with a thin insulating compound. (3) The number 40 was a typographical error; the number of slots must be 41. (4) Yes. (5) Multiply the efficiency by 746 and divide the dynamo output in watts by the result. Thus, if the efficiency is 0.91 and the output in watts 75,000, the horsepower required at the shaft will be 75,000 ÷ 0.91 × 746 = 110.5 scant.

What is meant by an "open-circuit" arc lamp? (2) What are its advantages? (3) How does a differential arc lamp operate? W. T. K.

A lamp in which the carbons are held apart by the mechanism when the lamp is cut out of circuit. (2) For alternating-current work the advantage is that only a shunt magnet is used for regulating and striking the arc, and the power factor of the lamp is higher than it would otherwise be. There are no advantages of importance in direct-current work. (3) A series magnet or winding strikes the arc and tends to keep the carbons apart; a shunt magnet or winding opposes the series magnet or winding and tends to release the upper carbon; when the arc is too long, the shunt magnet overpowers the other and allows the carbon to feed.

In transferring a three-phase alternator from one set of bus-bars to another without shutting down, the machine fell slightly out of step and took a heavy cross current to pull in again. The two sets of bus-bars were connected by transformers during the transfer; in changing over, one leg of the alternator was transferred, while the other two remained connected to the first bus-bars, then the second leg, and finally the third. The machine was adjusted to take a slight motor current before transferring. Why did it get out of step? L. A. S.

Because during the interval while the second leg was being transferred the machine was not connected operatively to either circuit and there was nothing to keep it in step. One leg was connected to the primary of the transformers forming the link between the bus-bars and the other leg to the secondary; consequently the machine received no current from the other generating sets.

If the power factor of an induction motor is 78 and the efficiency 82% with an input of 48 kilowatts *apparent* power, what will be the actual power? (2) What are the essential points to be covered in a set of specifications for a direct-connected engine and generator, the engine to operate non-condensing at 125 lbs. initial pressure and the generator to be a constant-potential, direct-current machine, for incandescent lighting? D. P. R.

The intake is 48,000 × 0.78 = 37,440 watts true power and the power at the pulley is 37,440 × 0.82 ÷ 746 = 41.15 horsepower. (2) The essential points cannot be given without writing the specifications practically in full. The principal points to be covered are the power by the engine at rated speed and initial pressure; steam consumed per horse-power developed at different loads; speed variation between no-load and full load; mechanical efficiency of the engine; commercial efficiency of the generator at half, three-quarters and full load; temperature rise of different generator parts at full load; overload ability without sparking or dangerous heating for one hour; the same for one minute; voltage regulation between no load and full load, taking into consideration the speed fluctuation of the engine.

Why is a railway motor more liable to spark and flash at the commutator than a stationary machine of equally reputable make? (2) Is the static capacity of ordinary central station primary lines large enough to require consideration in laying out circuits? (3) What causes a direct-current multipolar generator to burn every third or fourth bar of the commutator while all the other bars remain in good condition except the near edges of the bars next to the burnt ones? W. T. K.

It is more likely to spark because it is a reversing machine and therefore the brushes must be set on the theoretical neutral line, while the armature reaction causes the actual neutral line to shift to one side or the other of the theoretical line, according to the direction of rotation. The tendency to flashing is due to the relatively small number of commutator segments and the jolting which the brushes receive from the car, causing them to bounce away from the commutator a slight distance. (2) Not unless the station is a long distance (say 10 miles or more) from the center of distribution or the lines are underground cables. (3) The armature slots contain either three or four coils, so that one of the group is not in the proper part of the magnetic field when it undergoes commutation; consequently, when the bar connected to that coil passes a brush, there is sparking, which burns the bar. The sparking may be ***under*** the edge of the brush and therefore invisible on casual inspection, but it is there.

RIDGWAY TWO-BELT CONVEYOR SYSTEM.

The accompanying engravings illustrate a departure from the usual belt-conveyor system, in that two belts are used in place of one. In the two-belt system an interior troughing and supporting belt runs over its individual head and tail pulleys, having separate take-ups, and is entirely independent of the conveying belt proper. The conveying belt is threaded over its head and tail pulleys in the usual manner, and has its separate take-up so that the two belts, although moving together are separate and distinct, and this enables the conveying belt to be lifted off the supporting belt and out of the troughing blocks and passed through either a stationary dumper or a movable tripper.

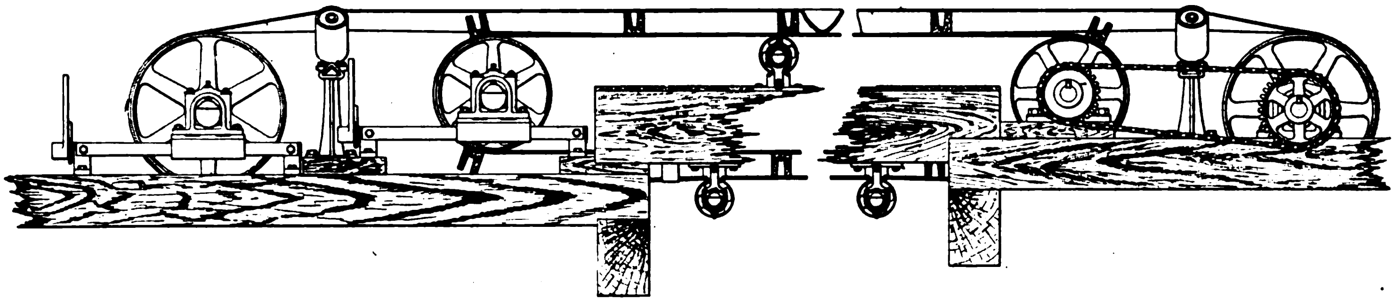

FIG. 1.—RIDGWAY TWO-BELT CONVEYOR.

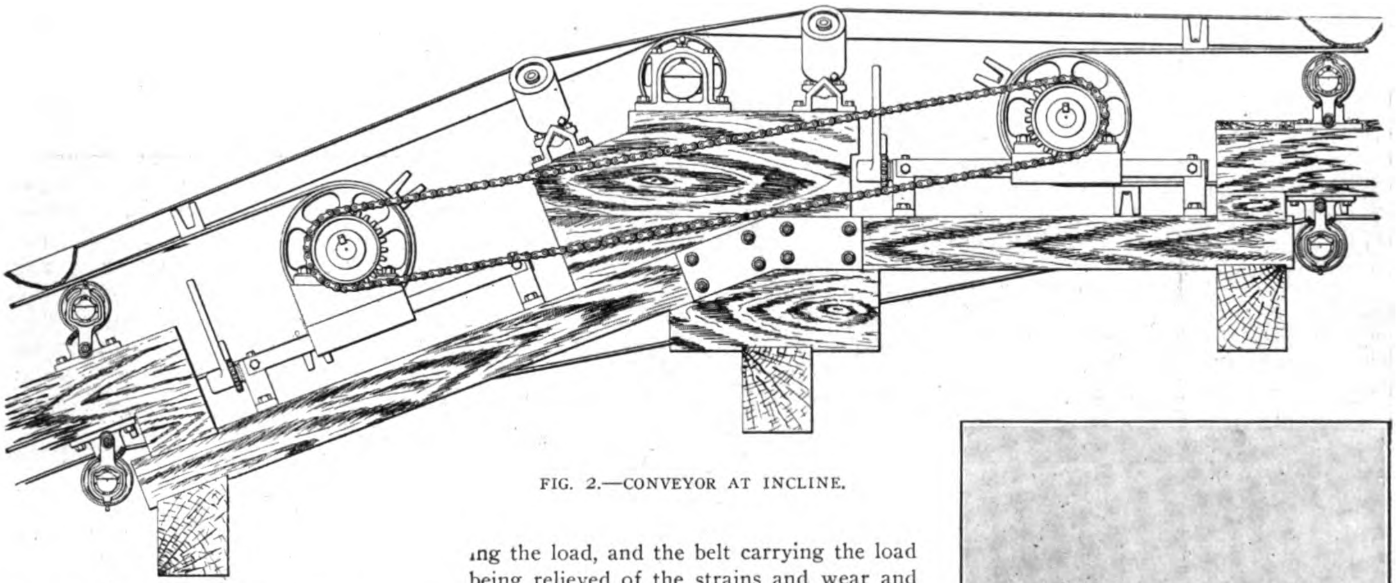

FIG. 2.—CONVEYOR AT INCLINE.

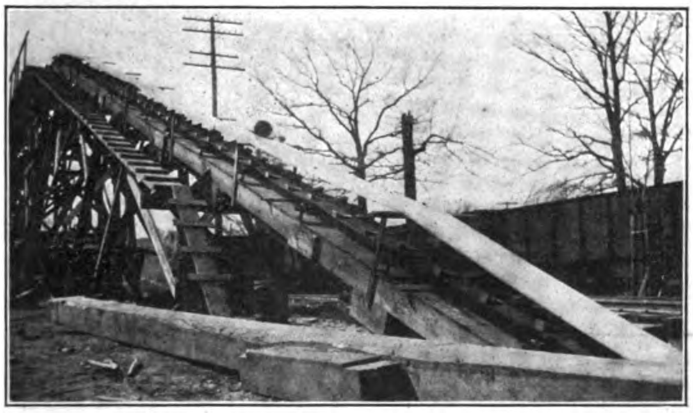

FIG. 3.—RIDGWAY CONVEYOR SHOWING TROUGHING BELT.

The conveying belt is said to have no work put upon it other than what is required to drive the lower carriers and its own head and tail pulleys; all the carriers on the upper line, which comprise two-thirds of the total number used, being revolved by the inner supporting belt. The strains, therefore, are divided, the belt revolving two-thirds of the moving parts not being subject to the wear and tear of carrying the load, and the belt carrying the load being relieved of the strains and wear and tear of revolving the majority of the moving parts of the machine.

The interior belt is driven by a compensating drive (roller or block chain sprocket drive) from the main driving shaft and with the two belts in tension just sufficient to prevent slip on their driving pulleys; both belts move at the same speed in the same direction, and there is claimed to be no rub of the conveying belt on the troughing blocks.

At the points where the conveying belt meets the interior supporting belt, a pair of concentrating rolls lifts the edge of the belt and drops it into the troughing blocks. This same method is used where the conveying belt leaves the troughing blocks at the opposite end.

The troughing blocks are made of whitewood, dipped in crude or linseed oil, to prevent checking, and are rivetted to the belt by 5-32" round, flat-headed, copper rivets. The carriers used are straight rollers fastened to steel shafts revolving in babbitted boxes, the boxes being ball and socket, ring-oiling, felt-washered and dust-proof. The carrier belt, or conveying belt proper, lies in a natural position, with the strains distributed, it is claimed, over its whole width.

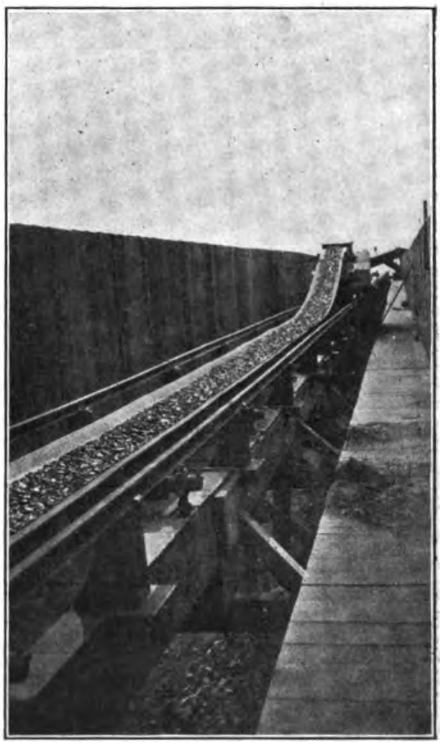

FIG. 4.—RIDGWAY CONVEYOR SYSTEM.

Fig. 3 shows the interior troughing and carrying belt with its troughing blocks attached. This interior belt by a compensating drive is driven at the same speed as the upper carrying belt and the two move together through their entire travel on both the upper and lower sides. The inner or troughing belt carries the outer or conveying belt through the upper line of working travel, and the outer belt carries the inner belt on its return, and through its travel in the lower line. The ability to use straight rollers enables the use of light castings. This has a double advantage in reducing weight and minimizing power. Only a clean belt comes in contact with the upper carriers, which comprise two-thirds of the total number used. The system is owned by the Ridgway Belt Conveyor Company, New York City.

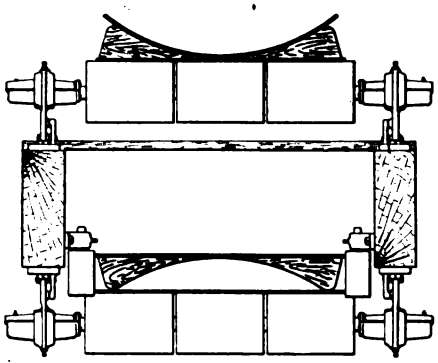

FIG. 5.—CROSS-SECTION OF CONVEYOR.

◆

UNDERGROUND CONDUIT SYSTEM AT MANCHESTER, MASS.

During the past month the conduit system of the Manchester Electric Company, at Manchester, Mass., has been completed. The work was begun last fall and the total trench feet opened was about 45,000. Manchester is a popular watering place on the Atlantic Ocean, having several fine beaches and bold promontories. It is 23 miles northeast of Boston on the Gloucester Division of the Boston & Maine Railroad, and is the summer residence district of many of the moneyed men of the Hub. The current for the most part is used for residential lighting.

A peculiarity of the system is that fully 30 per cent of the conduit is embedded in rock. The size of the duct run varies from two ducts at the outlying ends of the system to the main run of nine ducts entering the power-house. In carrying out the work an organization of about 450 men was required and a complete outfit of drills, together with a stone-crushing plant. Here all of the granite excavated from the trenches was crushed to a size suitable for concrete.

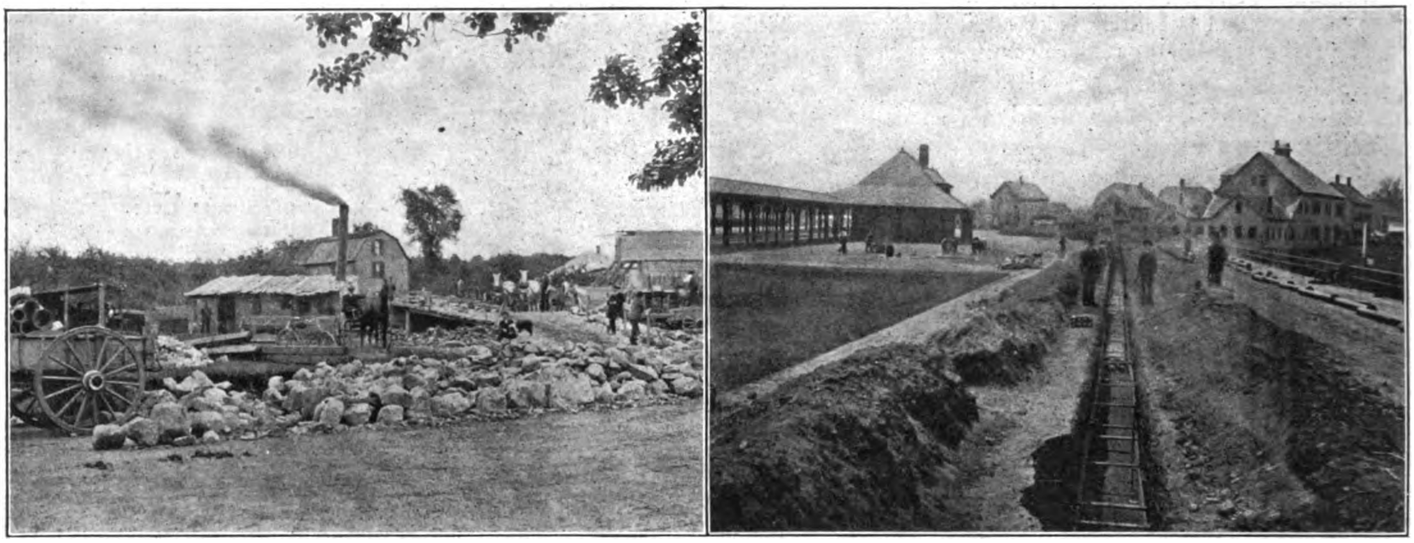

FIG. 1.—ROCK-CRUSHING EQUIPMENT AND CONDUIT TRENCH AT MANCHESTER.—FIG. 2.

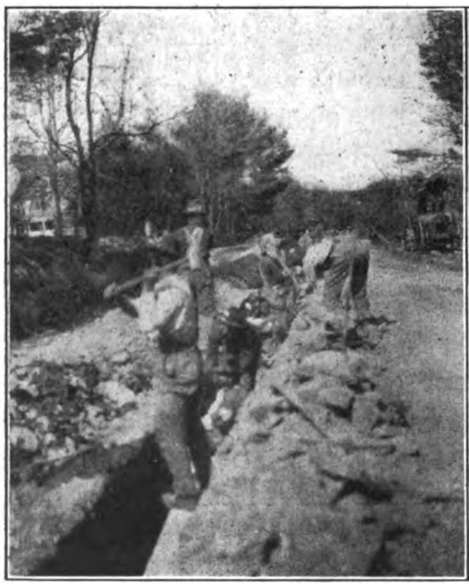

FIG. 3.—DRILLING A TRENCH IN THE ROCK.

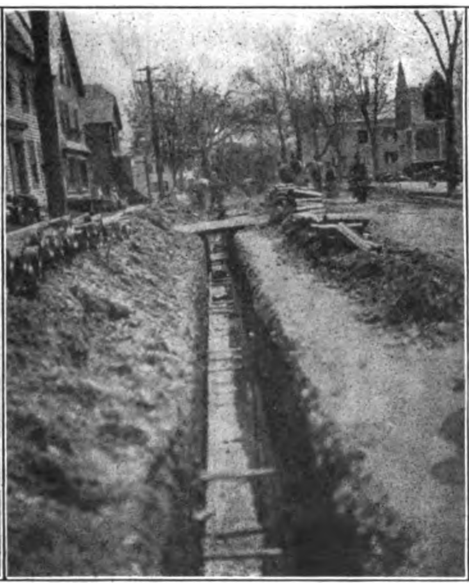

FIG. 4.—CONDUIT TRENCH.

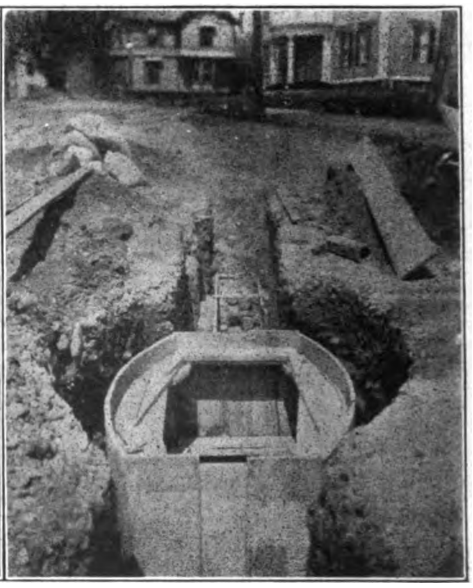

FIG. 5.—CONCRETE CONDUIT FORM.

After the trenches were excavated to grade, a line of boards or boxes was placed in the trench for the purpose of giving a straight line of trench and also to economize in the use of concrete, since the trenches were excavated by blasting with dynamite the resulting width being much greater than was required for the installation of the conduits. After the boxes were placed in the trenches a layer of concrete 3 inches thick was placed on the bottom. Upon this the tile ducts were laid and the space between the sides of the boxes and the tiles, 3 inches, was filled with concrete, and then 3 inches of concrete was placed on the top, thus encasing the tile completely in concrete.

The manholes, of which there are over 200, were built for the most part of concrete. A few brick manholes were built where a great quantity of water was encountered, and in some cases manholes of collapsible steel were installed. These are made in two pieces and keyed on the curved side of the form.They are then given the desired shape by means of turnbuckles. The concrete manholes were built as shown by Fig. 5.

After the sides had been filled with concrete and allowed to set for 48 hours, the forms were removed and the manholes roofed over by placing I-beams across the top and filling in the space between the beams with concrete. The manhole casting was then set on top of this roof.

Where the ducts enter the manhole they are recessed 4 inches from the inner face of the manhole wall. Thimbles are built in each manhole, so that when connections are desired for house service it is not necessary to cut into the manhole walls. All the ducts are laid in straight lines, any turns necessary being made in the manholes; so that oftentimes these are 30 feet apart, while in other cases they are 300 feet apart. Macadam roads are used throughout the town.

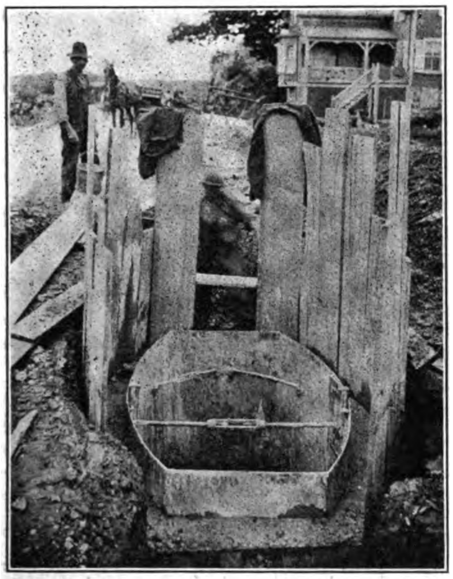

FIG. 6.—COLLAPSIBLE STEEL MANHOLE.

The work was carried on under the supervision of the chief engineer of the Manchester Electric Company, G. W. Palmer, Jr., and L. R. Cobb, resident engineer. Mr. G. M. Gest, of New York, was the contractor for the entire conduit system.

STURTEVANT STANDARD AND PONY ECONOMIZERS.

The amount of heat rejected with the smoke and waste gases in the generation of steam above that which is necessary for the production of a suitable natural draft is in most cases excessive; so that the utilization of economizers in connection with steam production is worthy of consideration. We illustrate herewith two types of economizers made by the B. F. Sturtevant Co., of Boston, Mass., which are almost similar in design and differ only in size. The "Standard" economizer shown by Fig. 1 is intended for use in conjunction with boilers of almost any capacity, but is more practical for boilers having capacities of 350 horsepower and over. The "Pony" economizer shown by Fig. 2 is built on a smaller scale and is more commonly used in connection with plants of from 50 to 500 horsepower capacity. It differs from the "Standard" only in some minor constructional details. The economizers are first and foremost flue feed-water heaters, but their value in the steam plant is not alone measured by the increase in the temperature of the boiler feed water.

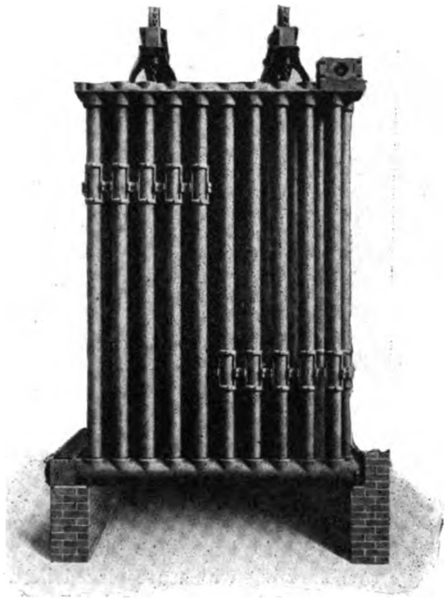

FIG. 1.—STANDARD ECONOMIZER.

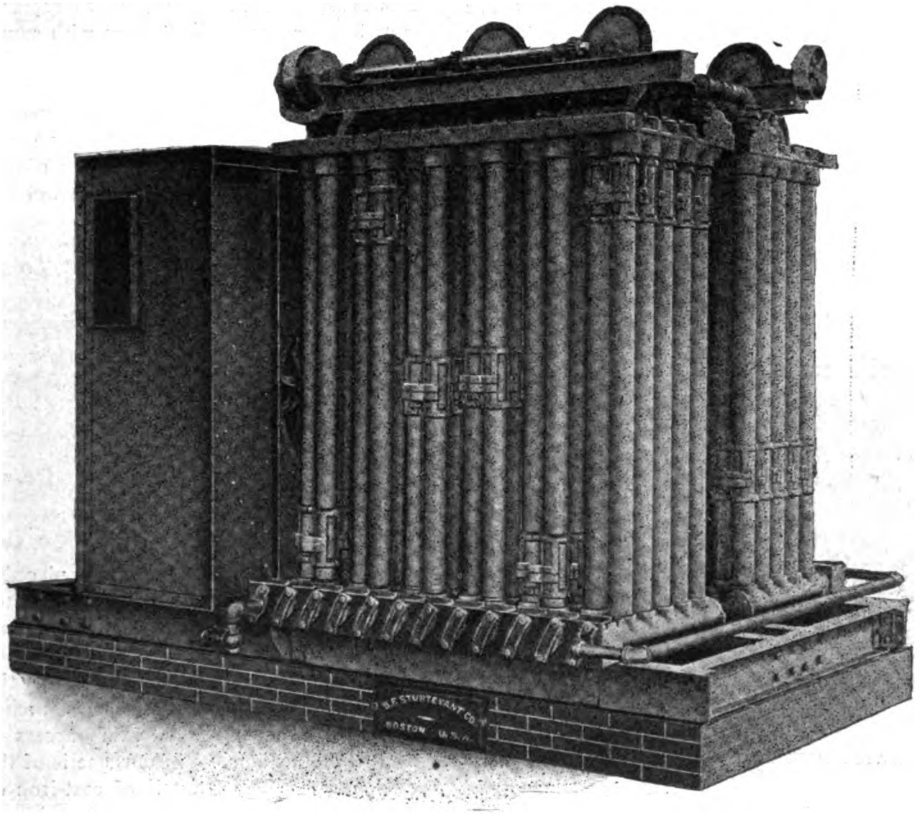

FIG. 2.—STURTEVANT PONY ECONOMIZER.

To agitate the gases and allow them to come into contact with the maximum area of the economizer pipes, thus utilizing a maximum amount of the waste heat from the boiler, a patent system of staggered pipes is employed. As will be seen from the illustrations the several sections are arranged to that the pipes of any one section are longitudinally opposite the spaces between the pipes of the adjoining sections. The economizer is also built with straight pipes.

As few joints as possible are employed and in order to make the deteriorating effect of joints as small as possible, each section is fitted into its wall box or branch pipe with tapered iron-to-iron joints, no packing being used. All caps are also fitted with taper iron-to-iron joints. Branch pipes are eliminated at the top of the economizer, and all the pipes used are of gray iron and cast on end. Both ends are tapered and the pipes forced into the headers by hydraulic pressure. The caps have taper ground iron-to-iron joints and can be easily removed. Those directly over the pipes in the top headers are tapered, while all of the others are held in place by through bolts. The bolts do not come into contact with the water and therefore are not subject to its deteriorating effects.

The headers are of cast iron, the bearing parts being machined and finished to gauge in order that the taper joints may be tight. As a substitute for the manifold header with its branch pipes, a wall box is employed. This is placed in the front side wall of the economizer. The economizers are fitted with relief valves, blow-off valves and cast-iron soot-pit doors. The foundations are

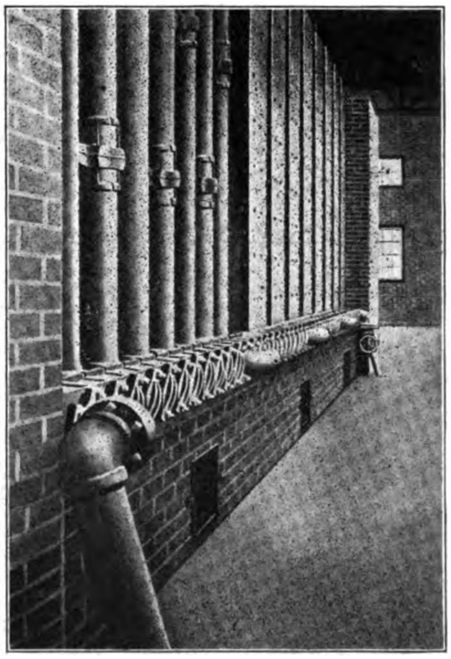

FIG. 3.—STANDARD ECONOMIZER CONNECTED.

usually of brick and sometimes of structural steel. With brick foundations a chamber is formed under the economizer in which soot accumulates. The inlet and outlet flues are of brick or sheet iron, and when of iron are built of double sheets about an inch apart filled with a non-conducting material.

◆

RUST WATER-TUBE BOILER.

Fig. 1 herewith shows a sectional elevation of the Rust water-tube boiler, manufactured by the Rust Boiler Company, of Pittsburg, Pa., and only recently placed on the market. The most novel feature in connection with the boiler is the special tube sheet used in the construction of the drums. This tube is formed by heating the fire plate to the proper temperature, then pressing in a hydraulic press fitted with dies especially constructed for that purpose, the pressing being done at one operation. An important feature of the construction of these tube sheets is that between each pressed-up portion and those adjacent there remain undisturbed cylindrical portions or belts of the original surface of the drum.

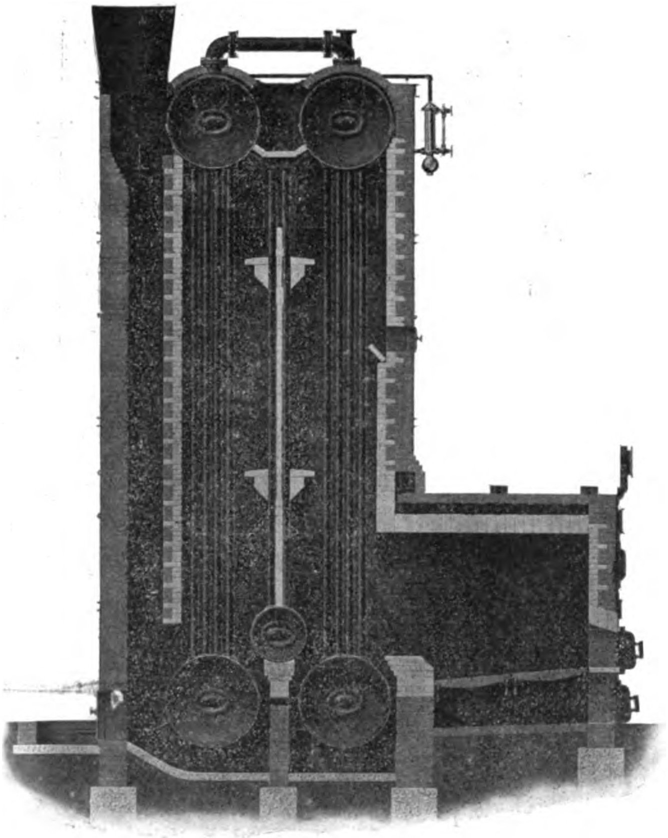

FIG. 1.—SECTIONAL ELEVATION OF THE RUST WATER-TUBE BOILER.

The boiler proper consists of two steam and water drums, two mud drums and an auxiliary drum, each steam and water drum being placed directly above a mud drum and connected by a bank of straight, vertical tubes, the two mud drums being connected by a row of tubes. The auxiliary drum is placed above and between the mud drums and is connected to one of them by a row of short tubes and to a series of small headers by a bank of straight vertical tubes. These headers are placed between the steam and water drums and connected by short, straight tubes or nipples. The holes for the tubes forming the main banks are so spaced that the tubes are staggered. Enough room is left between the tubes of the outside rows to remove the tubes of the inner rows. By the introduction of the auxiliary drum and central bank of tubes, the space necessarily left between the main banks of tubes is so utilized as to secure a serviceable and convenient support for the baffle wall, the tiles forming which are placed between and supported by the rows of tubes forming this bank, and owing to the consequent increased heating surface a boiler of larger capacity results without additional floor space, fittings or cost of setting. The boilers are made right and left hand, and are arranged to be set singly or in batteries of two. Each drum is provided with a manhole in one end to permit of access to the interior of the drum, and in the top of each header there is an oblong handhole through which to reach the interior of the tubes of the central bank. The steam spaces of the steam drums are connected by cross-pipes of liberal dimensions. On top of each is an outlet, on which is placed a safety valve. The steam outlet is placed on top of and at the center of the rear steam and water drum. The boiler is supported by four large cast-iron saddles resting on masonry foundations, one saddle being placed under each end of each mud drum, the saddles under one of the drums being placed on rollers so as to permit of any slight movement that may be necessary on account of expansion. By referring to the sectional view of the boiler it will be observed that the top of the central baffle wall is far enough below the headers to leave sufficient space for the products of combustion to pass from the front to the rear bank of tubes. It will also be observed that there are horizontal baffles or bracket tiles which project from this central baffled wall, and which serve to deflect the current of hot gases so as to force them toward and between the tubes of the main banks. At the top of the setting and bolted to the corner binders is placed a box-shaped frame made up of channels and plates, which furnishes a rigid support for the breeching and stack, and also serves to firmly bind the brickwork at the top of the setting, and at the same time results in a neat finish. On one side of the setting, near the top, are placed four small doors, which furnish access to the interior of the brickwork, and through which the tubes are passed in and out when replacements become necessary. Doors with small, self-closing openings, through which to insert a hose for blowing off the top of the tube sheets, are placed near the bottom of the setting, and other doors are furnished for securing access to the interior of the setting and for blowing deposits from the exterior of tubes. Over each steam and water drum and a little above it is placed a light steel arch, which serves as a center to support the brick arches over the drums to permit all possible upward expansion of the boiler, without interfering with the brick covering. Between the two arches are placed doors through which access is given to the headers. The furnace is of the exterior type. The front is of cast-iron of ornamental design, surmounted with a bracket in the center for supporting the steam gauge, and is so arranged as to permit the application of gas burners or any form of stoker.

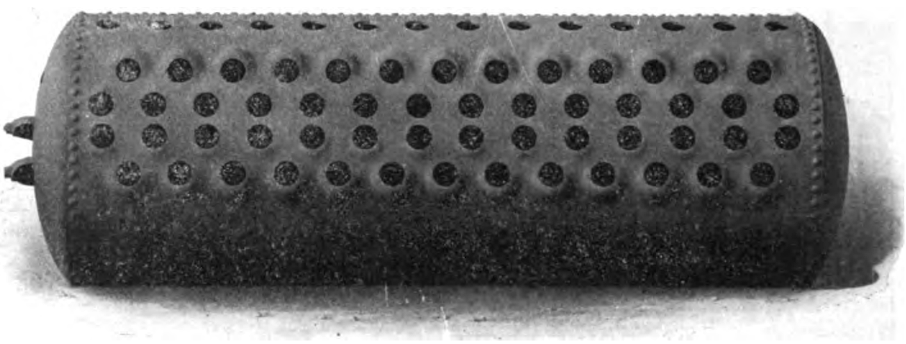

FIG. 2.—DRUM OF RUST WATER-TUBE BOILER.

New Apparatus and Appliances

UNIVERSAL SHADE AND SOCKET.

Figs. 1 and 2 show two types of universal shade and socket brought out by the D'Olier Engineering Company, of Philadelphia, Pa. These electrical devices are among the latest on the market and were designed for use over desks, in draughting rooms and machine shops, and in fact any place where concentrated light is necessary. A particular feature of the shade and one to which the manufacturer calls attention, is that it is balanced when suspended from a flexible cord. Another feature is that both the shade and the socket can be turned completely around so that light can be had in any desired direction. The shades are made in three different finishes—polished brass, brush brass or brass body with green shade. As will be observed from the illustrations the devices are pleasing in appearance. They are, moreover, well made and the part next the lamp is painted with aluminum so as to add to its reflecting qualities.

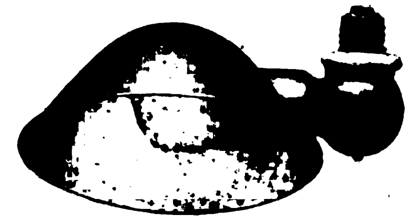

FIG. 1.—UNIVERSAL SHADE AND SOCKET.

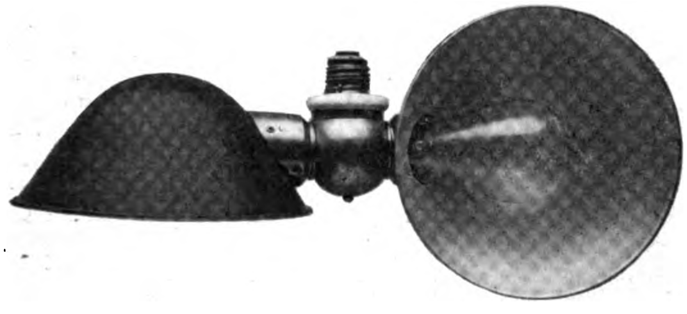

FIG. 2.—UNIVERSAL SHADE AND SOCKET.

RICHMOND "TYPE R. E." MOTORS AND GENERATORS.

Fig. 3 herewith shows one of a line of new direct-current motors brought out by the Richmond Electric Company of Richmond, Va., and designated "Type R. E." The usual circular frame is employed, the feet being cast with the frame and sticking well out with a wide spread. The armatures are made of thin steel accurately punched, annealed, rolled and japanned. They are then keyed upon the shaft and pressed together between malleable iron heads under hydraulic pressure. The heads form in one piece the thrust collars and oil slingers, and being shrunk on prevent the creeping of oil along the shafts from the bearings and getting into the windings and commutator. The head at the commutator end forms, as shown, a large taper on which the commutator shell fits. The commutator is held in place on this taper by a lock nut. Liberal bearings are provided, the linings being of aluminum bronze. The armature windings are composed of form-wound coils, being pressed to shape in steam molds. The commutator leads are swedged into the commutator bars, no solder, acids, etc., being used. The coils are held firmly in place by steel band wires which come below the surface of the core. The field coils are carefully wound on forms. They are not wound on bobbins, but are like the field coils of railway motors. The pole pieces are built of sheet steel punchings riveted together between end plates. The pole pieces are accurately fitted to the finished pole seats on the frame and are held in position by steel cap screws. They are readily removable and the projecting tips hold the coils firmly in place. The motor heads are cast in one piece and seat in counterbores in the frame and are held in place by four cap screws. The commutators are built on malleable iron shells which fit on the taper of the armature heads. The bars are deep and thoroughly insulated and are held to the shell by a malleable iron ring and lock nut, the latter being screwed down hard, while the commutator is under hydraulic pressure. The brush-holders are of brass and are simple in construction and design. Radial adjustment of the holder is provided so as to permit reduction of the commutator diameter without changing the angular distance between brushes. The carbon brushes slide in finished ways. The holders are securely bolted to the yoke, which is of paraffine soaked maple. The yoke is bolted to the brush-holder ring as shown. This ring clamps on the finished shoulder provided for it on the motor head. A projection on the ring goes into a recess in the head, this recess being of such a size as to permit a small movement of the ring in either direction from the neutral point. Terminal posts are avoided, the double rubber-covered leads being brought direct from the coils and brush-holders through rubber bushing inserted in holes drilled in the frame casting, thus adopting street railway methods. With commutator clean and brushes properly set, the motors are claimed not to spark under 200 to 300 per cent load. The motors are also built fully enclosed or semi-enclosed. The "R. E." type generators are built in sizes up to 20 kilowatts and for standard voltages from 100 to 500.

HANGER FOR CABLES AND PIPES.

Fig. 7 herewith shows the Atlas hanger, which has been designed with a view to providing a simple hanger for electric conduit pipe, flexible conduit, wire cables and pipes of every description. The hanger itself is of ornamental design and by its use pipe can be hung one inch from the ceiling or support. The hanger requires no assembling or adjustment and when necessary it may be separated for changes to the pipe line. The style A hanger shown by Fig. 7 is furnished with either adjustable beam clamp, toggle bolt or expansion screw and is made for pipes from ¾ to 1 inch. As shown in Fig. 8 it consists of a hollow spherical casing in two halves, mounted to turn on a pivot. By means of two small screws, the casing grips the pivot firmly, the whole being thus combined as one piece. The casing is supplied with outlets diametrically opposite each other for the passage of pipes, cables, etc., or for supporting the ends of pipes carrying feed wires as in a junction box. The clamp is of malleable iron and is made in two parts provided with longitudinal slots, so as to be adjustable to any size of I-beam. Fig. 10 shows the hang-

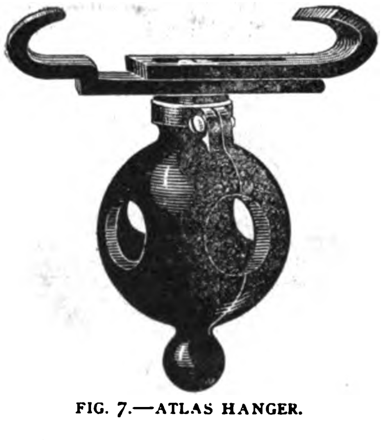

FIG. 7.—ATLAS HANGER.

er provided with a wooden screw. Style D hanger is shown in Fig. 9 and is especially adapted for large sizes of pipes. It has a pivot arrangement similar to the one shown in Fig 7 but a malleable iran ring is substituted for the hollow sphere, thus adapting it for steam, water and other large sizes of pipe. In order to make the hangers adaptable to various purposes they are supplied with pivots for use with ordinary beam clamps, lag screws, toggle bolts, etc. Where a perfectly insulated support is desired, the pivot is covered with a heavy layer of hard rubber. Style J hanger corresponds to style A, but is especially adapted for use as a junction box. The interior is coated with a heavy enamel and then baked, resulting in a smooth, polished surface which prevents the abrasion of the wires and possesses good insulating qualities. The hanger is made by the Atlas Hanger Manufacturing Company, of New York.

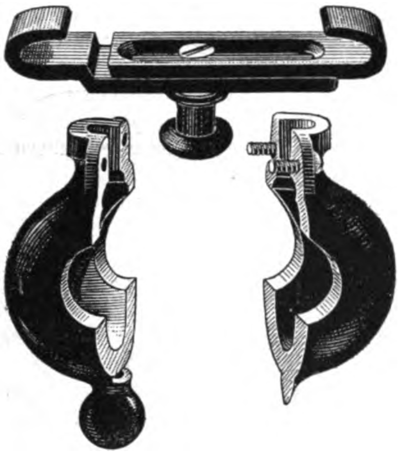

FIG. 8.—ATLAS HANGER DISASSEMBLED.

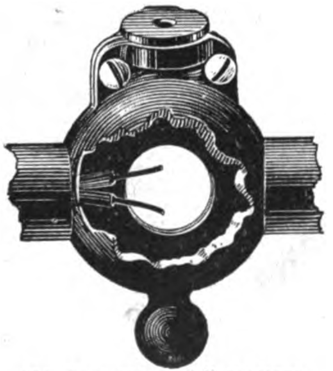

FIG. 11.—STYLE "J" HANGER.

LONG SCALE PORTABLE INSTRUMENTS.

Electrical engineers who employ the portable standard instruments in general use for the making of exact measurements of electrical quantities know how difficult it is to take accurate observations in those portions of the scale where the divisions are narrow, and the consequent uncertainty regarding results and difficulty in checking up a series of measurements taken with different instruments. The fact that only a portion of the scale is accurately legible and that it is not always possible to have at hand instruments of the proper range to cover all capacities properly, make it at times impossible to avoid the use of comparatively illegible divisions, and as a result the curve sheets of tests and tables of measurement show irregularities. To obviate such troubles the Department of Standards of the Westinghouse Electric and Manufacturing Company has designed the portable instruments illustrated herewith. The assortment comprises voltmeters, ammeters and single-phase and polyphase wattmeters. Their principal characteristics are convenience in use, permanence of calibration, accuracy and mechanical excellence.

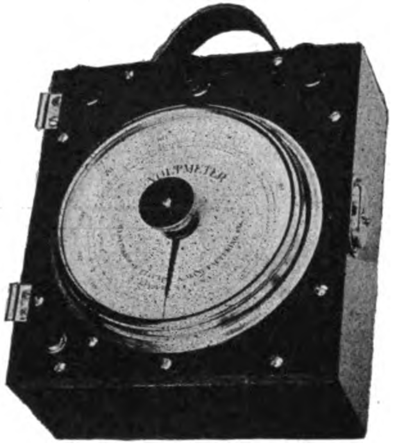

FIG. 12.—PORTABLE VOLTMETER.

As shown by the illustration, the voltmeter is zero-reading, this form having been found most suitable for measurements for which a voltmeter is used. In this form the readings are determined by the deflection of the milled head required to bring the index pointer to zero. Each instrument is made in two capacities, which in connection with the long scale enables the readings to be taken over a wide range of voltage with accuracy. It is astatic and therefore unaffected by external fields, and may be used on either alternating or direct currents. It is regularly made in capacities up to 600 volts, but may be furnished for any higher range desired by the use of a multiplier. The action is dead-beat. The ammeter is similar in external appearance to the voltmeter, with the exception of the terminals, which are designed for the use of heavier connecting wires, and the absence of the knurled head with its indicating pointer, this instrument reading direct. It is furnished with coils wound in two sections, which, by means of small connectors on the top, may be connected in series or in parallel, thus increasing the range of the instruments. The scale is long and open, being similar to the voltmeter in this respect. This instrument can be used on alternating currents only, but it is accurate over a long range of frequencies and may be used on circuits varying from 3000 to 8000 alternations without appreciable error. It is also said to be unaffected by changes of wave form on the circuit. The moving element is light, and being dead-beat will follow any variation of current. In the wattmeters, the scheme of subdividing the coils as adopted for the ammeters is carried out for both the series and potential windings, thus giving in one instrument four ranges in capacity. In addition to this, as the scales are uniformly spaced

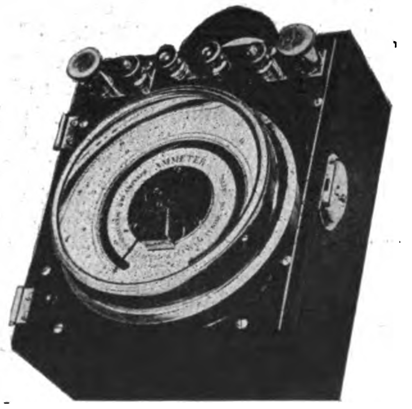

FIG. 13.—PORTABLE AMMETER.

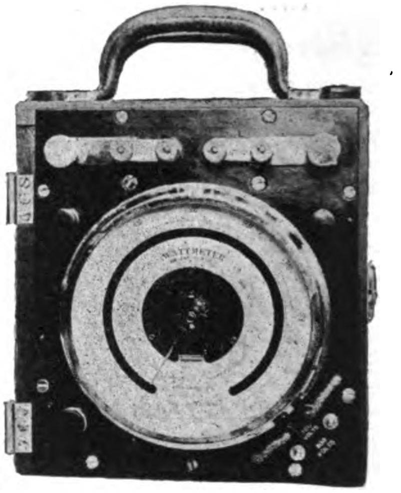

FIG. 14.—PORTABLE POLYPHASE WATTMETER.

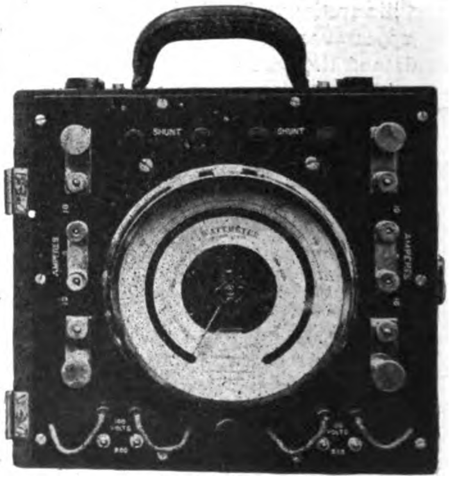

FIG. 15.—PORTABLE SINGLE-PHASE WATTMETER.

from zero to maximum, readings may be taken at any point with equal accuracy, so that one instrument will give a very large range. The wattmeters are suitable for use with alternating currents only, but like the ammeters, they may be used over a considerable range of frequency. The polyphase instrument consists of two singlephase mechanisms connected to one shaft, and indicating on a single dial the sum of the forces of the two mechanisms. It may be used for either two-phase or three-phase circuits and will, it is said, indicate correctly the total energy of a polyphase circuit irrespective of power factor or any unbalancing of the different phases.

BRISTOL'S THERMOMETER-THERMOSTAT.

The Bristol Co., of Waterbury, Conn., is placing a new instrument upon the market which combines a thermometer and thermostat. The instrument will give correct indications of the temperature of the atmosphere, gases or liquids at all times, and also serve as a thermostat to make electric connection at any predetermined limits of temperature for the purpose of operating controlling apparatus, alarms and the like. The construction and capabilities of this instrument will be best understood by referring to the interior view, Fig. 16, in which *A* is an arm pivoted at lower portion of the case, terminating in a point resting on the arc of the graduated scale and is held by friction at whatever point it may happen to be set. Two adjustable contact pieces, *B* and *C*, are carried by this arm. These contact pieces are capable of adjustment by means of a screw *D*, which is threaded so as to cause the contact pieces *B* and *C* to approach or recede at equal rates and distance from the center line of the arm *A*, upon which they are supported. They are also connected to binding posts as shown, which are used for making outside connections. These binding posts are located within the case. Three holes with insulating eyelets are provided in the lower portion of case, as shown, for the insertion of connecting wires. The arm *E*, moving over the graduated scale, indicates the changes of temperature where the instrument is located.

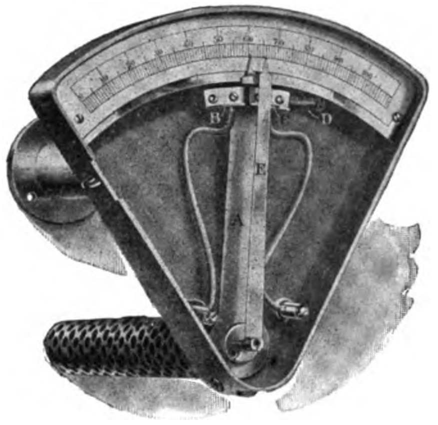

FIG. 16.—BRISTOL THERMOMETER RHEOSTAT.

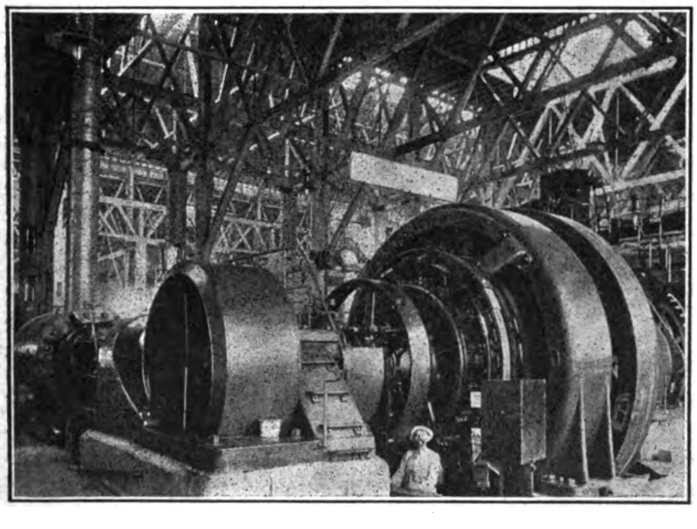
This arm is operated by a recording thermometer tube placed in the perforated protecting projection extending from the back of the case as shown in the illustration. On the back of the indicating pointer *E* there is a raised portion which makes electric connection with the contact pieces. A novel feature of the instrument is that the temperature indicating arm *E* is not restrained by the thermometer-thermostatic contacts. Thus it will be seen that the controlling effect of the thermostat is adjustable as to position on the scale of the thermometer, and also as to high and low limits of operation, without in any way interfering with the indications of the thermometer in case the temperature does not remain, or is not controlled, within the limits for which contact pieces may be set. The instrument may be readily applied to liquids, as for instance to indicate the temperature and set into operation controlling apparatus for the brine in a refrigerating system or tank. For temperatures above the atmosphere, as those occurring in ovens, kilns, closed spaces, and liquids in pipes under pressure, a small bulb is located within the closed space or pipe. This bulb is connected with the thermometer-thermostat by a capillary tube filled with alcohol. The electric wires connecting with the adjustable thermostatic contacts may be carried to any point where the controlling apparatus may be located or where it is desired that an alarm shall be given.

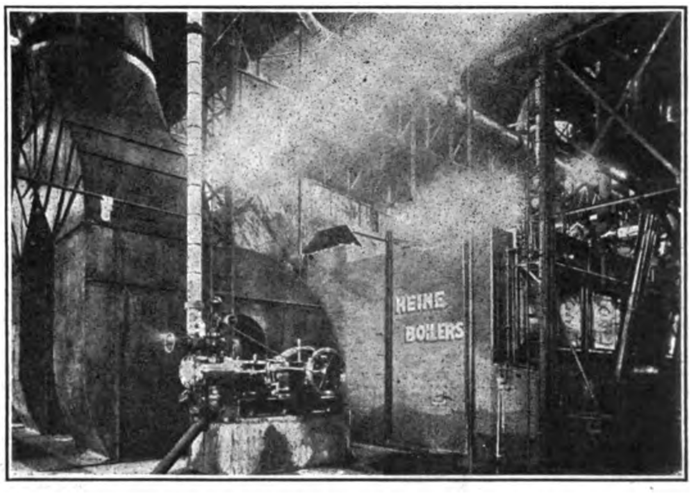
SOME EXHIBITS AT THE ST. LOUIS EXPOSITION.

We published last month a description of some of the exhibits at the Louisiana Purchase Exposition at St. Louis, and we describe this month as many additional exhibits as space limitations will allow. This by no means exhausts the number of available exhibits for description. Some of the larger exhibits, notably those of the Westinghouse and General Electric Company, will be described in a later issue.

CROCKER-WHEELER CO., Ampere, N. J., has as its exhibit all of the 500-volt, direct-current generators in the Machinery Building which supply the Intramural railway. The largest generator, which is of 900-kw. capacity, is direct connected to a Buckeye engine; two generators of 500 kilowatts are direct connected to Brown-Corliss engines; one generator of 600-kw. capacity is direct connected to a Lane & Bodley Corliss engine; a 400-kw. generator is operated by a Fleming four-valve engine, and a 500-kw. generator is operated by a Murray Iron Works Corliss engine. All these generators supply current through a railway switchboard built by the Walker Electric Company, of Philadelphia. The generators have given very satisfactory service since the opening of the Intramural railway.



CROCKER-WHEELER GENERATOR.



HEINE SAFETY BOILER COMPANY'S EXHIBIT.

HEINE SAFETY BOILER COMPANY, St. Louis, has a bank of boilers in the boiler house and an exhibit showing the construction of the Heine boilers and their different parts in the northwest corner of Machinery Building. In the boiler plant there are eight single-shell boilers rated at 400 horse-power each. These boilers are designed for a working pressure of 175 pounds to the square inch. Each boiler has 178 8-in. tubes and a drum 48 ins. in diameter. They are equipped with Green traveling chain grates, supplied with fuel from overhead bunkers, and in common with all the boilers in this plant are connected to induced draft apparatus. The company's exhibit space in Machinery Hall has a part of a full size Heine boiler showing the construction of the boiler heads, and also a complete model of a Heine boiler. The quality of steel tubing used in Heine boilers is illustrated by some tubing which has undergone very severe treatment in the way of bending and flattening without breaking.

THE EDISON COMPANIES' booth is divided into three sections, the central one being the headquarters of the American Institute of Electrical Engineers, the one to the right the office of the Association of Edison Illuminating Companies, and the one to the left the office of the Edison historical exhibit. The Edison Storage Battery Company's exhibit occupies an adjoining space. Three of the latest types of the Edison battery are shown, one cell of each type having part of the side cut out so as to show the internal construction. A 40-cell automobile battery is connected to a charging board to show the conditions under variable rate of charge and discharge and to demonstrate the high rates which can be used without effecting the battery. The different parts used in the construction of the cells are contained in a showcase. Plates are exhibited from a cell of an automobile which has run 4000 miles over rough roads. An historical collection of Edison storage cells is shown in a case, beginning with the first cell made and showing one of each type. There are also bottles containing nickel and iron oxides and graphite used in filling the pockets of the plates. A bottle containing electrolyte with all the sediment from a cell which supplied current to propel an automobile 5000 miles is also on exhibition. Enlarged curves showing the battery voltage at various discharge rates are displayed on the wall. Then different types of the Edison-Lalande primary battery and some fan motors operated by them are exhibited, as are also several of the Edison projecting kinetoscopes.

THE BRISTOL CO., Waterbury, Conn., makers of the Bristol instruments, make the handsome display shown in the engraving. The instruments of this company are successfully applied to the continuous recording of current voltage, wattage, steam pressure, water pressure, height of the water level, and temperatures up to stack temperatures of 800° F. An improvement which users of Bristol instruments will appreciate is exhibited; this is termed a stationary dial instrument, in which instead of removing the circular steel plate when charts are to be changed, the chart only in removed. This is slipped under guides in the vicinity of the recording pointer so that there is no necessity of removing the pointer or danger of bending it and throwing the instrument out of adjustment when renewing a chart. An ingenious instrument for recording slight variations in pressure is shown. This can be calibrated for use in indicating the level of water in a tank or the height of the tide. It consists of a recording pressure gauge connected to a long, thin, covered tube about the size of No. 12 wire outside diameter. Upon the end of this tube is a solid metal cylinder which, with the recording pressure gauge, is filled with the liquid. The tube is anchored to the bottom of the tank in which the rise and fall of level is to be measured. The variation in the depth of water cause variations in pressure which are recorded on the chart of the recording pressure gauge. An electrical alarm attachment can be used in connection with the recording instruments made by this company, so as to sound an alarm when the instrument records either high or low or both. One of the new instruments shown is an alternating-current recording wattmeter. All of the different types of instruments are ranged so that their operation can be demonstrated, and a 5000-ampere recording ammeter for use on station bus-bars is also exhibited.

THE TRIUMPH ELECTRIC COMPANY, Cincinnati, Ohio, has a comprehensive exhibit. Power for operating is received from a Warren synchronous motor driving a 35-kw., 220-volt Triumph generator. A Fairbanks-Morse vertical gas engine direct connected to a 7½-kw., 220-volt generator is also in use. A motor-generator receives current from this unit and converts it into current at 500 volts. A number of machine tools are shown in operation, illustrating the method of connecting the Triumph motors. A band saw is driven by a motor and intended for one speed only. A motor-driven drill is regulated by a Cutler-Hammer drum starter and controller. A Lodge & Shipley lathe is similarly equipped and in operation. All of these motors are designed for 220 volts. The machinery which forms the inoperative part of the exhibit consists of a 100-kw., multipolar, engine-type generator and a series of motors ranging in size from ½ horse-power to 25 horse-power. In order to illustrate the details of construction a large armature core is partially wound. Other detail parts are also shown.

ROTH BROTHERS & CO., Chicago, show small motors and generators which have been adapted to special lines of work. One dynamotor is used for ringing bells in telephone exchanges, with attachments for the "howler," "busy back," "automatic ringing" and "pulsating" current for party lines. Electric grinding and polishing lathes, forge blowers and motor-generator charging sets from 1-16 horse-power to 15 horse-power form interesting features of the display.

THE ELECTRIC CONTROLLER AND SUPPLY COMPANY, Cleveland, Ohio, exhibits a new system of control where the service requires frequent reversals of the driving motor under load. This control has been applied chiefly to the table motors in steel mills where a stop from full speed and an acceleration to full speed in the reverse direction of a 50-h.p. motor under load is required in less than thirty seconds. The adaptation of this system to planers is shown on a 36-in. planer, driven through one pinion and gear by a 6-h.p. variable-speed motor. The motor being direct connected is reversed at each end of each stroke of the planer. The motor is compound-wound, but the series field is only used for acceleration and is short-circuited when the motor comes up to speed. The speed of the cut and return may be varied independently and through a very wide range. The planer is shown in actual operation cutting iron and steel. Another operating exhibit is made by the company in connection with the Niles Tool Company in Machinery Hall, where a 90-h.p. electric reversing clutch operates a 12-ft. planer. A three-ton lifting magnet attached to a hoist is shown lifting steel plates and billets. Magnetic friction brakes and a cushion type of solenoid are shown in operation. The remainder of the space is filled with a line of controllers.

THE NATIONAL CARBON COMPANY, Cleveland, Ohio, has a display which is of interest not only on account of the great variety of carbons shown, but because the massive pillars and railings of the booth are of carbon made from the regular products of the company. These, for the most part, are duplicates of those used in large electric furnaces and electrolytic work.

THE STANDARD UNDERGROUND CABLE COMPANY, of Pittsburg, and the McROY CLAY WORKS, of Brazil, have a unique exhibit in the Electricity Palace. This shows on a small scale the operation of laying underground conduit and drawing lead-covered cables into the ducts. This conduit is laid under the floor at about the depth it would ordinarily be laid beneath the street surface, and the opening in the floor permits the visitor to descend by stairways and examine the conduit, which is shown in various stages on construction. There are two manholes and cable is being drawn from one to the other. The conduit consists of 72 ducts, some completely laid and some partly finished so as to show the method of wrapping the joints between lengths of tile and placing the concrete at the top and bottom of the duct. A reel of the Standard Underground Cable Company's cable, such as is used in construction work, is placed on the main floor of the building above one of the manholes, and in the manhole at the other end is a capstan rigged up for drawing in the cables. From the manholes the cables go to distributing poles, to illustrate the method of supplying overhead distribution from underground lines.

ACHESON GRAPHITE

A GROUP OF EXHIBITS AT ST. LOUIS.

1. Edison Illuminating Companies. 2. Intramural Railway Car. 3. The Bristol Company. 4. General Electric Company. 5. Triumph Electric Company 6. Sub-station. 7. Roth Brothers. 8. Electric Controller & Supply Company. 9. National Carbon Company. 10. Standard Underground Cable Company and McRoy Clay Works. 11. Acheson Graphite Company.

ACHESON GRAPHITE COMPANY, Niagara Falls, N. Y., has a space near the entrance of the building and displays miniature electric furnaces which illustrate the processes of E. G. Acheson of manufacturing graphite from anthracite coal and similar raw material. The different grades of graphite and electrodes of various sizes and forms are shown, the latter containing practical working samples of different anodes and electrodes as used by the customers of this company for electrolytic work. They illustrate the different methods of machining and assembling the graphite into economical anode forms. For electric furnace work, the electrodes can be joined together end to end into the furnace one after the other as consumed without interruption of the furnace. The graphite bulk products well illustrate the importance of this article in the manufacture of paint, dry batteries, stove polish, motor-generator brushes, etc. Special attention is given to the use of this form of pigment for high-grade productive coatings on structural iron and steel.

PERSONAL.

MR. H. C. SPAULDING has been appointed assistant sales manager of the Triumph Electric Company, Cincinnati.

MR. HARRY R. KING, the designing engineer of the Western Electric Company, of Chicago, was married recently to Miss Irene Baker, of Leadville, Colo.

MR. B. L. FREEDY, who has for many years been manager of the St. Paul system of the Northwestern Telephone Exchange Company, has been advanced to the position of superintendent, with headquarters at Minneapolis.

MR. PAUL DOTY, for several years general manager of the Denver Gas & Electric Company, has been appointed to the same position with the St. Paul Gas Light Company, which controls the St. Paul Edison Electric Light & Power Company.

MR. FRANK W. FRUEAUFF has been appointed general manager of the Denver Gas & Electric Company. Mr. Frueauff has been secretary and treasurer of the company for some time.

MR. S. P. GRACE, engineer of the Central District & Printing Telegraph Company, Pittsburg, Pa., has had the honorary degree of Master of Engineering conferred upon him by the State University of Michigan.

MR. JOHN R. CULLINANE, who has been connected with the Denison (Tex.) Lighting & Power Company for the past eighteen years, has resigned the secretaryship of that company to accept the management of the Texarkana Lighting & Power Company.

MR. CHARLES D. KNIGHT, who has been for many years well known throughout the electrical industry, has resigned his position with the National Electric Company, of Milwaukee, and joined the engineering staff of the Cutler-Hammer Company, of that city.

MR. A. L. WATERBURY, who was for some time first vice president and general manager of the Citizens' Telephone Company, Houston, Tex., has been appointed general manager of the sales department of the American Conduit Company, with headquarters at the Chicago office of that company.

MR. W. S. CONE, formerly foreman of the new steam turbine station of the Los Angeles Edison Company, has been appointed chief engineer of the American Falls Power, Light & Water Company, Pocatello, Idaho, where he has charge of extensive improvements in the steam and hydraulic equipment of that company.

MR. RALPH H. BEACH, who has been connected with the railway department of the General Electric Company about seventeen years, has severed his connection with that company and will devote his entire attention to the management of the Tula Iron Works Company, Tula, Mexico, in which he owns controlling interest.

MR. LOUIS TERVEN has been appointed chief electrician of the Nernst Lamp Company, Pittsburg, Pa. Mr. Tervan was for some time electrician at the United States Navy Yard, Port Royal, S. C., which position he resigned to enter the experimental laboratory of the Nernst Lamp Company. Later he was given charge of the Chemical Engineering Department of this company.

MR. ROBERT GREGORY recently delivered an interesting address on mechanical methods of cleaning boilers before the Keystone Association, a chapter of the National Association of Steam Engineers. Mr. Gregory is a practical engineer of many years' experience, and his paper covers the question of boiler cleaning very thoroughly. It has been reprinted in attractive form and copies may be obtained without cost upon application to Mr. Gregory at 112 Wood Street, Pittsburg.

MR. WALTER H. WHITESIDE.

MR. WALTER H. WHITESIDE has been appointed general sales manager for the Allis-Chalmers Company, including, of course, the Bullock Electric Manufacturing Company, which comprises the electrical department of the Allis-Chalmers Company. Mr. Whiteside's business experience has not been confined to the electrical field. In 1881 he became connected with the DuPont Powder Company, of Wilmington, Del., and introduced the high explosive products of that company into the Lake Superior region. Four years later he became associated with the Cleveland Electrical Manufacturing Company, of Cleveland, Ohio. He remained with that concern nearly twelve years, serving during the first two years in various capacities, and for the remainder of the time being the manager of their Chicago office. In 1896 Mr. Whiteside was appointed manager of engine sales for the Gates Iron Works, of Chicago. In 1898 the Westinghouse Electric & Manufacturing Company made him the manager of its Washington office. In that position he became associated not only with the largest electrical projects undertaken in the district which his office covered, but in other places farther afield, his engineering work in connection with the installation of electrical power in the Dry Docks of the Navy Department, especially the docks at Portsmouth, League Island and Boston, having been widely recognized. To him was largely due the credit of the change from 80 to 125 volts in the electric lighting and power installations on board the vessels of the U. S. Navy But Mr. Whiteside's best work in the commercial sense was the building of that immensely successful branch of the Westinghouse Electric organization known as the Detail & Supply Department. Into this department he injected a new life and vigor of administration that won for him recognition for marked executive ability. About a year ago he was appointed general manager of the Sawyer-Man Electric Company, of New York, thereby practically doubling his duties, for he continued the management of the Detail & Supply Department of the parent company at Pittsburg. Mr. Whiteside is a man of force and also of attractive personality. He would be a strong man for any industrial concern, and it is difficult to know whether to congratulate the more the Allis-Chalmers Company, which has secured his services, or himself for becoming identified with that powerful concern.

MR. R. M. JONES, for the past five years chief engineer and general superintendent of the Pike's Peak Power Company, Victor, Colo., has severed his connection with that company to engage in consulting engineering. Mr. Jones is prepared to take up any work in connection with hydraulic and electric plant construction or design or as consulting engineer or supervising constructing engineer. His experience in hydraulic-electric work in the West qualifies him admirably for this class of engineering. His present address is 1455 Josephine Street, Denver, Colo.

MR. A. M. MATTICE, chief engineer of the Allis-Chalmers Company, has returned from his European tour of inspection, and has now settled down to the duties of his position in Milwaukee. While in Europe Mr. Mattice visited the hydraulic machinery works of Escher, Wyss & Company, of Zurich, and arranged important details concerning the manufacture in the United States of their lines of product. He also inspected the Nurenberg Gas Engine Works, at Nurenberg, and, at the well-known engineering establishment of Willans & Robinson, at Rugby, England, he paid particular attention to the products and methods of manufacture of the Steam Turbine Advisory Syndicate, of which important organization the Allis-Chalmers Company is the American member. Mr. Mattice had several important consultations in London with Mr. Yarrow, the famous torpedo boat builder, on the subject of turbines for marine purposes, and while on the Continent he made, in the Allis-Chalmers interests, a series of exhaustive tests of the Zoelly steam turbine, of which so much has recently been heard.

TRADE PUBLICATIONS.

INSULATING MATERIALS. H. W. Johns-Manville Company, New York.—A pocket size pamphlet, comprising a complete price-list of standard mica, oiled linen, Vulcabeston, and other insulations.

RECORDING PRESSURE AND VACUUM GAUGES. The Bristol Manufacturing Company, Waterbury, Conn.—Catalogue No. 13 of the well-known Bristol recording meters for vacuum and pressure work.

GAS ENGINE GENERATOR UNITS. The Meriam-Abbott Company, Cleveland, O.—A small, well-executed pamphlet, containing illustrations and a brief description of the gas engine-dynamo units built by this company.

MULTIPLE-VOLTAGE MOTOR SPEED CONTROL. The Bullock Electric Manufacturing Company, Cincinnati.—Bulletin No. 1028, superseding bulletin No. 1009-A and devoted to the well-known Bullock multi-voltage system.

GUARANTEED TELEPHONES. Electric Gas Lighting Company, Boston, Mass.—A vest pocket pamphlet, containing illustrations and brief descriptions of the Samson and Samson, Jr., telephone outfits manufactured by the E. G. L. Company.

HIGH-TORQUE INDUCTION METERS. General Electric Company.—Bulletin No. 4379, containing an illustrated description of the Thomson high-torque induction type of meter. These meters are built for the standard voltages and frequencies.

MACHINE TOOLS. The Garvin Machine Company, New York.—A pocket size catalogue of drill presses, engine lathes, planers, shapers, presses and grinding machinery carried in stock by the Garvin Company at its New York warehouse.

TYPE H TRANSFORMERS. General Electric Company.—Publication No. 9132, superseding publication No. 9144 and containing an illustrated discussion of the Type H oil-cooled transformer. The pamphlet is handsomely executed and profusely illustrated.

AIR COMPRESSORS. National Electric Company, Milwaukee, Wis.—Bulletin No. 350, containing an illustrated description of this company's Type H and Type L motor-driven air compressors. The catalogue is handsomely executed and liberally illustrated.

ELECTRICAL SUPPLIES. Manhattan Electrical Supply Company, New York.—This is catalogue No. 18, covering the complete aggregation of apparatus and supply lines manufactured and handled by this company. The number of lines covered by the catalogue is too great for enumeration.

MOTOR-DRIVEN BLOWERS. The Emerson Electric Manufacturing Company, St. Louis.—Bulletin No. 3055, containing a description and illustrations of motor-driven forge and volume blower fans. The motors are the well-known Emerson direct-current machines, built for all the standard voltages.

DIRECT-CURRENT GENERATORS. The Bullock Electric Manufacturing Company, Cincinnati. —Bulletin No. 1029, superseding No. 1008 and containing a profusely illustrated description of the Bullock engine-type direct-current dynamos. The bulletin is well executed and the description interesting.

AUTOMATIC STEAM ENGINES. The Buckeye Engine Company, Salem, O.—This is a handsome catalogue containing a very complete description of all of the types of Buckeye engine. These engines are now built in the vertical as well as horizontal types and in both center-crank and side-crank forms.

GENERATING PLANT OF THE INTRAMURAL RAILWAY. Crocker-Wheeler Company, Ampere, N. J.—This is bulletin No. 47, devoted to the electrical equipment of the Intramural Railway power house at the St. Louis Exposition. The equipment consists of seven Crocker-Wheeler generators, each of 750 kilowatts capacity.

COMMUTATOR GRINDER. The Phillips Machine Syndicate, Ltd., London.—A catalogue of the Phillips patent commutator grinder, which differs radically from all of the portable or semi-portable machines commonly used in this country for trueing commutators in that the work is done by grinding instead of by means of an ordinary lathe tool.

INTERIOR TELEPHONES. Electric Gas Lighting Company, Boston, Mass.—Bulletin No. 1, the full title of which is "The Specializing of Interior Telephone Apparatus." The bulletin is in reality a very complete and handsomely executed catalogue of Samson and Samson, Jr., telephones, and contains illustrations not only of the outfits, but of every individual piece of mechanism contained in each outfit.

DYNAMO AND MOTOR APPLICATIONS. Northern Electrical Manufacturing Company, Madison, Wis.—A series of fliers, comprising leaflets Nos. 120-A, 121, 128, 130 and 131, each containing an illustration of a Northern dynamo or motor and the machine with which it is operated. The leaflets show dynamos driven by gas engines and steam engines and motors driving different classes of machinery.

BUSINESS NEWS.

JAMES McCREA & COMPANY, Chicago, have appointed Braman, Dow & Company, Boston and Worcester, Mass., agents for the sale of the H. H. steam trap.

H. W. JOHNS-MANVILLE COMPANY, New York, has secured the contract for equipping the new residence of Louis C. Tiffany with Noark fuses and magnesia pipe covering.

PASS & SEYMOUR, INC., of Solvay, N. Y., report large sales of their new fuseless rosette for concealed wiring installations. Each sample sent out makes a friend and produces orders.

THE NATIONAL WIRE CORPORATION, of New Haven, Conn., on August 1 removed its general and executive offices from New Haven to New York City. The address is 114 Liberty Street.

THE KEYSTONE LUBRICATING COMPANY, Philadelphia, manufacturer of the well-known Keystone grease, has appointed Herbert Carpenter general agent for Boston and the vicinity.

CROUSE-HINDS COMPANY, Syracuse, N. Y., through F. M. Hawkins, New York agent, reports the recent shipment of 180 Imperial headlights to Dick, Kerr & Co., London, for use in a plant at Yokohama, Japan.

THE MERIAM-ABBOTT COMPANY, Cleveland, Ohio, has on exhibition at the St. Louis Exposition an 18-h.p. gas engine-generator unit which is located in the exhibit space of the Ewing-Merkle Electric Company, St. Louis representative.

WESTON ELECTRICAL INSTRUMENT COMPANY, Newark, N. J., has made an arrangement with the Cutter Company, of Philadelphia, whereby the latter company is to sell the well-known Weston central station instruments.

CROCKER-WHEELER COMPANY, Ampere, N. J., has arranged with the well-known manufacturing establishment of Brown, Boveri & Cie., Baden, Switzerland, to manufacture in this country the complete alternating-current line of machinery originated by C. E. L. Brown.

THE VILTER MANUFACTURING COMPANY, Milwaukee, Wis., reports a heavy trade in refrigerating machinery. A list of contracts recently closed includes 22 refrigerating plants, 8 Corliss engines and 23 orders for ammonia condensers, piping, and other fittings for refrigerating plants.

THE PITTSBURG GAGE & SUPPLY COMPANY, Pittsburg, Pa., reports among recent orders for White Star oil filter systems, equipments for the Carnegie Steel Company, Homestead, Pa., Nashville (Tenn.) Railway & Light Company, Allegheny City Lighting Station, and the Harris Steam Engine Company, Providence, R. I.

MORE WESTINGHOUSE APPARATUS FOR SOUTH AFRICA. The De Beers Mines Company, of Kimberly, South Africa, has ordered a third Westinghouse turbine-generator of 1500 kilowatts capacity. The turbine unit will be similar in all respects to the two which have been in operation during the past year.

THE D. & W. FUSE COMPANY, Providence, R. I., is particularly gratified over the closing of a large contract for cut-outs and fuses for the Manhattan elevated system of New York. The order was secured entirely on merit, after subjecting the D. & W. fuses to severe tests in competition with those of other makers.

THE WESTINGHOUSE COMPANIES invite the electrical fraternity at large to visit their headquarters in the Palace of Electricity, Machinery and Transportation at the St. Louis Exposition. The companies have extensive exhibit spaces in all three buildings, and attendants are, of course, at hand to welcome visitors and do what is necessary for their comfort.

BROWN-CORLISS ENGINE COMPANY, Corliss, Wis., at a recent meeting of the stockholders, voted to increase its working capital $150,000. The company has just established a department for building high-speed engines and is now at work on two 150-h.p., three 250-h.p., one 75-h.p., and two 50-h.p. engines, all of which are to be direct-connected to electric generators.

THE JONES ELECTRIC & MANUFACTURING COMPANY, of New York, has been incorporated under the laws of the State of New York with a capital stock of $50,000 for the purpose of manufacturing telegraphic instruments, apparatus and supplies. The officers are S. F. Jones, president; F. G. Smith, vice-president, treasurer and general manager; H. H. Sherman, secretary, and C. Wachtel, superintendent.

ALLIS-CHALMERS COMPANY, Milwaukee, extends a cordial invitation to visitors to the St. Louis Exposition to make use of the facilities provided at its Exposition space in Machinery Building. Visitors will find here a comfortable resting place, writing tables, stationery, and attendants who will receive and forward mail and telegrams, check parcels, and do all that is possible for the comfort of visitors, without charge, of course.

ELECTRICAL EQUIPMENT & SUPPLY COMPANY, Pittsburg, Pa., has obtained the representation in Western Pennsylvania of the Gilmore Electric Company and the Electric Gas Lighting Company, of Boston, Mass., and will represent the lines of those companies exclusively in the territory mentioned. The company has recently put on the market the "Esco" dry battery, "Esco" wet battery, and "Esco" soldering paste, all of which are meeting with very gratifying success.

THE REEVES ENGINE COMPANY, New York and Trenton, has established a branch office at Philadelphia, under the management of W. E. S. Dyer. The Philadelphia office is located at 2220 Land Title Building. The company recently installed in its factory at Trenton what is said to be the largest cylinder boring machine ever built in this country. The machine weighs 35 tons, and is to be used for boring engine cylinders and engine frames. It is capable of boring four cylinders simultaneously. Among the company's recent sales was an engine to the Diamond Rubber Company, Akron, Ohio, for connection to a 150-kw. generator; also one vertical cross-compound to the Brier Hill Iron & Coal Company for direct-connection to a 250-kw. generator.

G. M. GEST, the well-known subway contractor of New York and Cincinnati, was awarded recently a contract for the construction of a heavy 20-duct conduit system through Cincinnati, leading from the new exchange to the Fremont Avenue exchange of the Cincinnati Bell Telephone Company. Mr. Gest has also been awarded a large contract for the construction of a conduit system through the lower part of Brooklyn, leading from the new power house of the Brooklyn Heights R. R. Company to its new sub-station. He has also closed contracts for the construction of an extension to the subway system of the Brooklyn Edison Company for a conduit system to be installed by the Oliver Chilled Steel Plow Works, South Bend, Ind., and for conduits systems for the South Bend (Ind.) Electric Company and the Toronto (Ont.) Street Railway Company.

ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, recently closed contracts for installations of "Chloride" accumulators for the following railways: Long Island Railroad Company, at Hamil, L. I.; Portsmouth, Dover & York Street Railway, Dover, N. H.; Petaluma & Santa Rosa Electric Railway, of California; Toledo (Ohio) Railways & Light Company, and the City Railway Company, Dayton, Ohio. Contracts have also been closed for batteries for lighting and power service with the Mutual Life Insurance Company, New York, and the Central Oil & Gas Stove Company, Gardner, Mass.; Westinghouse, Church, Kerr & Company have ordered over 2000 cells of "Chloride" accumulators for use in train lighting on the New York, New Haven & Hartford railroad, and over 600 cells have been ordered for the Atchison, Topeka & Santa Fe Railway Company for signal service. Increases have been made in the plants of the Lancaster (Ohio) Traction Company, the Denver, Champaign Railway Company, St. Joseph, Ill., the Danville Street Railway & Light Company, Georgetown, Ill., and the Rochester (N. Y.) Railway & Light Company.

THE BIG ALLIS-CHALMERS ENGINE AT ST. LOUIS.—The central feature of the machinery exhibits at the World's Fair in St. Louis is the huge Allis-Chalmers engine coupled to a Bullock generator. This colossal unit is the most powerful ever placed on exhibition. The engine is capable of developing 8000 horse-power when operating condensing, at 150 pounds steam pressure, and running at 75 r.p.m. It is not merely a display feature: it furnishes the electric current for the decorative lighting of the buildings and grounds, for which about 200,000 incandescent lamps are used. The exhibition authorities frequently employ it for other purposes as well, sometimes for operating the cascades and sometimes for general power purposes. Recently it was suddenly called upon to take the entire load ordinarily carried during the day by a large plant in the same building, and aggregating about 5400 horse-power. Having carried this load as long as it was needed, the Allis-Chalmers giant then took up the regular lighting work for the evening The St. Louis Transit Company, which operates the larger part of the street car system in St. Louis, has been short of power many times since the World's Fair began to attract large numbers of visitors, and the company applied to the World's Fair authorities for additional power, with the result that from 2 P. M. until 7 P. M., when the loads are heaviest, the service of the big Allis-Chalmers engine is at the service of the traction company.

CENTRAL STATION NEWS

ALABAMA.

LUVERNE.—City Clerk A. B. Brooks writes that it is proposed to construct water works and an electric light plant here to cost $10,000.

BIRMINGHAM.—Extensive improvements are now under way at the plant of the Birmingham Railway, Light & Power Company. These include new boilers and a new 1500-kw. alternator.

EAST LAKE.—A franchise has been granted to the Birmingham Railway, Light & Power Company for the installation of an electric light system in East Lake.

SHEFFIELD.—The Sheffield Company has begun the work of erecting the poles for the new electric light system which is to be installed here and will push the work to completion as rapidly as possible.

PRATT CITY.—Several arc lights have been placed in the business portion of the city by the Birmingham Railway, Light & Power Company. It is proposed to have lights placed all over the city in the near future.

CHEROKEE.—Plans have been perfected by the Cherokee Development & Mining Company for the construction of a 25,000-h.p. plant on the Tallapoosa River at this place. The power thus developed will be transmitted to Birmingham, 85 miles distant, for the purpose of augmenting the 100,000 horse-power already in use there. The main dam will be 100 feet high and constructed of granite. The plant when completed, including the long transmission line, will represent an investment of $2,000,000. Mr. Henry C. Jones, of Montgomery, is engineer for the company.

ARIZONA.

TUCSON.—The Consolidated Telephone, Telegraph & Electric Company has filed articles of incorporation with a capital of $2,500,000. The company proposes to furnish current for lighting and power purposes and will expend a large amount in improvements and extending its lines to Old Mexico. The company's headquarters will be in this city.

ARKANSAS.

GRAVETTE.—An electric light plant is soon to be established here.

NASHVILLE.—It was recently voted by the citizens fo construct an electric light plant and water works.

WALNUT RIDGE.—The Walnut Ridge & Hoxie Light, Power & Traction Company has in contemplation the construction of three-quarters of a mile additional street railway track. Mr. Charles Miller is superintending the plant.

MAGNOLIA.—Mr. E. A. Brown, of the Magnolia Ice & Light Company, writes that bids will be received at once for the construction of an electric light plant which will probably cost about $25,000.

EARLE.—Mr. H. A. Morrison, secretary of the Earle Improvement Company, writes that bids for the construction of water works, a sewerage system and an electric light plant will not be called for in two or three months. The cost has not yet been estimated and no engineer has been engaged.

NORTH LITTLE ROCK.—A petition has been submitted to the Council by the property owners in this city for the construction of water works and an electric light plant.

CALIFORNIA.

ANGELS CAMP.—The Angels Electric Company is now owned and operated by the Utica Gold Mining Company.

HEALDSBURG.—Preparations are being made toward the establishment of an electric light and power plant at this point.

EUREKA.—The plant of the Eureka Lighting Company was destroyed by fire a short time ago. The loss is estimated at from $60,000 to $100,000.

SACRAMENTO.—The Sacramento Electric, Gas & Railway Company is installing a new switchboard and arranging to extend its distribution lines.

LOS ANGELES.—Mr. John Johnson, Jr., representing Los Angeles capitalists, has petitioned for franchises for gas and electric light plants at Oceanside and Escondido.

SAN BENITO.—The San Benito Water, Light & Power Company has been incorporated by Messrs. L. A. Gibbons, A. I. Little, G. T. Drinkwater and others, with a capital of $300,000.

CORONA.—The Corona Gas & Electric Company recently issued bonds to the amount of $40,000 for the purpose of meeting its indebtedness and to enable it to complete and extend its plant.

SONORA.—The Tuolumne Water & Power Company, of this city, has decided to extend its power transmission line from Jacksonville to Big Oak Flat and Groveland. Mr. J. B. Pownall is superintendent and purchasing agent.

LOS ANGELES.—The equipment at the plant of the Los Angeles Gas & Electric Company is being increased by the addition of a 300-kw., 500-volt, direct-current, direct-connected engine-generator set and 1000-h.p. Stirling boilers.

MERCED.—The Merced Falls Gas & Electric Company is installing new machinery and making additions which will double the capacity of its power plant. A new 225-kw. generator with exciter has been ordered and the buildings are being enlarged.

BLACK DIAMOND.—Application has been made by the Redwood Manufacturing Company for a franchise authorizing it to erect poles along the streets here to carry wires for the transmission of electric heat and power throughout the town. Bids were received for the franchise on May 17.

OAKLAND.—Articles of incorporation of the Century Electric Company of Alameda County have been filed with the County Clerk. The directors are Messrs. F. M. Greenwood, C. M. Wood, E. H. Weihe, John P. Maxwell and R. C. H. Hartley. The capital stock of the corporation is $50,000.

FRESNO.—The San Joaquin Power Company is said to be figuring on two more water power plants in the mountains and will probably put in 1500 kilowatts additional steam power at its plant in Fresno. The company also contemplates building additional pole lines from Fresno to its power house sites, a distance of 36 to 40 miles.

LOS ANGELES.—Mr. W. S. Cone, formerly foreman of the new steam turbine station of the Edison Electric Company of Los Angeles, has accepted a position as chief engineer of the American Falls Power, Light & Water Company, of Pocatello, Idaho, and has charge of some extensive steam and hydraulic improvements for that corporation.

SAN FRANCISCO.—The Mutual Electric Light Company, of this city, has broken ground at the site of its new electric generating station at the corner of Spear and Folsom Streets. Two 1500-kw. Bullock polyphase generators are on hand which will be direct-connected to two Pennsylvania Iron Works horizontal engines. The boiler contracts are to be let soon, in order to have the new plant installed in time to help out the old station with the "peak" load of next winter.

SAN FRANCISCO.—The public lighting contract for the year beginning July 1 has been awarded to the San Francisco Gas & Electric Company for $320,000 on an all-night schedule every night in the year. The contract provides for 1112 arc lamps, 5335 Welsbach gas lamps, the illumination of the dome of the City Hall on twelve nights, the lighting of all public buildings except park and school buildings, and the furnishing of power for elevators. The company also agrees to install 100 new arc lamps and 200 new gas lamps.

MENDOCINO.—The Mendocino Electric Light & Power Company, which recently took over the plant of the Mendocino Lighting Company, is making improvements at the plant, putting in new line extensions, etc. The company is capitalized at $25,000 and is officered as follows: President, Mr. J. Grindle; vice-president, Mr. J. G. Ross; secretary, treasurer and manager, Mr. A. Brown; superintendent, chief engineer and electrician, Mr. J. W. Heap. Besides Mendocino, the company's plant furnishes electricity for lighting the towns of Caspar, Little River and Albion.

LOS ANGELES.—Mr. O. H. Ensign, electrical and mechanical engineer of the Edison Electric Company of Los Angeles, has been appointed consulting electrical engineer of the U. S. Reclamation Commission, and is now on a trip of two months through the states of the arid West in company with Chief Engineer Newell, of the Commission. Mr. Ensign will investigate and report on the feasibility of hydro-electric power development in connection with the many hydraulic works which the Commission has under way and in contemplation, a task for which he is especially qualified by reason of his long and successful experience in developing the water power plants of the Edison Electric Company, with which he retains his connection.

COLORADO.

DENVER.—Mr. Frank W. Frueauff has been appointed general manager of the Denver Gas & Electric Company.

CONNECTICUT.

MERIDEN.—The Meriden Electric Light Company is installing a direct-connected unit consisting of a 380-h.p. Westinghouse engine and a 200-kw. generator.

NORWICH.—The council expects to make extensive improvements at the city plant which has recently been acquired by the city from the Norwich Gas & Electric Light Company. Bonds to the amount of $235,000 were issued by the council for the purchase of the plant and property.

NORFOLK.—The amount of $10,000, which was to be raised by the Norfolk people in order to reorganize the Norfolk Electric Light & Power Company, has been secured and the new company will be organized as soon as possible. It is probable that the streets of the village, which have been without lights for nearly two months, will be lighted again in the near future.

NORWALK.—Mr. William J. Burr has resigned his position as superintendent of the electric light department of the Connecticut Railway & Lighting Company. Mr. Burr had been connected with this company and its predecessor for over twelve years; for five years of that time he was superintendent of the system, which also included the electric lighting and power house on Wilton Avenue. It is understood that Mr. Burr has received a very flattering offer elsewhere.

CHESHIRE.—The large electric transformer station of the Connecticut Railway & Lighting Company in this place is now completed and in a short time all electric cars in this section will be propelled by power transmitted from the dynamos at Bull's Bridge near New Milford. These dynamos are operated by water-power obtained by means of a dam on the Housatonic River. Power is transmitted from the Housatonic power house to Cheshire over a high-tension line at 30,000 volts, where it is stepped down to 500 volts before being

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

distributed to the trolley lines. Besides the transformers, the equipment of the station includes three large rotary converters and a "booster." The total output of the station is about 1800 horsepower. The plant is housed in a brick and iron building 140x100 feet. The route of the transmission line is from Bull's Bridge to Waterbury and thence through Cheshire to New Britain, a distance of 60 miles.

FLORIDA.

WEST PALM BEACH.—The work of building the new boiler house and installing the 200-h.p. boiler at the plant of the East Coast Electric Light, Power & Ice Company has been completed. The installation of the new boiler will double the boiler capacity of the plant, which has been handicapped heretofore by lack of power.

TAMPA.—One of the most important and far-reaching movements in the industrial development of southern Florida is now practically under way. The waters of the Withlacoochee River are to be harnessed and electric power generated for the operation of the large phosphate plants and mills in Citrus, Marion and Levy Counties. The Camp Phosphate Company will at once begin the construction of the great dams on the river near this point. It will not only supply power for its own plants and mills, but for other corporations and manufacturing establishments, and electric lighting for adjacent towns and cities.

GEORGIA.

OCILLA.—The Council is considering the matter of constructing an electric light plant.

LA GRANGE.—An election is to be held soon for the purpose of voting on the question of issuing $25,000 bonds for the erection of an electric light plant.

LOUISVILLE.—A bond issue of $10,000 has been voted by the citizens, the amount to be devoted to constructing water works and an electric light plant.

BATESBURG.—It was voted at a recent election to bond the town for $20,000 for the purpose of establishing an electric light plant, water works, and other permanent improvements.

STILLMORE.—An electric light plant is to be installed here, the enterprise being backed by home capital. The work of stringing the wires is now in progress and the plant will be put in operation as soon as possible.

WALLACOOCHEE.—The Town Council has prepared a bill to be introduced in the Legislature, authorizing the issuance of $10,000 bonds for public improvements, consisting of a new school, an electric light plant and a water works system.

GAINESVILLE.—The big dam of the North Georgia Electric Company, which has been in course of construction on the Chattahoochee River near this city for nearly two years, has just been completed. Mr. E. S. Copeland has recently been elected secretary of the company.

ELBERTON.—The indications are that the Calhoun water power on the Savannah River, near this city, will soon be developed, as parties have been on the field to abstract titles. Application will be made to the next Legislature for the right to dam the river at a point twelve miles from here.

MACON.—A petition for a charter for the Piedmont Power Company has been made by Messrs. Robert L. McCabe, F. M. Marriatt, William A. Carlisle and Charles F. Howe. It is their purpose to organize a company with a capital of $2,000,000 to utilize the water power of Georgia and neighboring states. The headquarters of the company will be in this city.

IDAHO.

WHITE BIRD.—The electric light plant here is to be enlarged.

BOISE.—The Crane Falls Power & Transportation Company has been incorporated for the purpose of constructing an electric power plant at Crane Falls, Owyhee County, the power generated to be used for the operation of the company's several plants. Among the directors are Messrs. William B. Dean and A. J. Nathacker, New York; Messrs. B. F. Olden and L. J. Weaver, of Boise, and others. The company is capitalized at $5,000,000.

MOSCOW.—Mr. E. S. Aldrich, vice-president and manager of the Moscow Electric Light & Power Company, states that a contract has just been closed with the Lewiston Water Power Company for power furnished by that company. He writes that his company is preparing to install sub-stations and distributing plants in this city and Genesee, Idaho, and Pullman and Uniontown, Wash., for the supply of power and light on a 24-hour circuit; it is probable that $2,500,000 will be expended in improvements and enlargements during the next five years.

POCATELLO.—The Bonanza Land, Power & Light Company was recently consolidated with the American Falls Power, Land & Light Company. The officers of the corporation, which is capitalized at $2,000,000, are Mr. A. H. Tarbet, president; Mr. J. H. Brady, general manager; Mr. D. W. Stanrod, treasurer, and Mr. W. S. Chaney, secretary. The consolidation gives the company 25,000 horse-power and practical control of the electric business of southeastern Idaho. Most of the power will be secured from American Falls. It is expected that eventually the company will extend its lines to Butte, Mont., for the purpose of supplying power to the mines there.

ILLINOIS.

SAYBROOK.—An electric light system is to be installed here soon.

SENECA.—The trustees of the town have decided to light the city by electricity.

STREATOR.—The People's Light & Railway Company is engaged in erecting a new power house.

WOODHULL.—The Woodhull Electric Light Company expects to install a new dynamo shortly.

ALEXIS.—It has been voted by the citizens to purchase the electric light plant here and operate it as a municipal plant.

WALNUT.—The plant of the Walnut Electric Light Company is now owned and operated by Messrs. W. H. Sayles and C. Dunbar.

GIBSON CITY.—Messrs. A. L. Phillips and L. J. Hiland, with others, have incorporated the Gibson Electric Light & Power Company, which is capitalized at $30,000.

CHICAGO.—The Universal Electric Company has filed articles of incorporation with a capital stock of $2500. Messrs. C. J. Holland and N. F. Higgins are among the directors.

CARTHAGE.—The Carthage Electric Light & Heating Company is putting in a new boiler equipment at its plant and is also contemplating the erection of a central heating plant.

HILLSBORO.—A franchise has been granted to the Hillsboro Electric Light & Power Company to erect and maintain electric light wires over the highways of the county for the purpose of extending its system.

GILLESPIE.—The Gillespie Electric Light Company has been incorporated, with a capital of $15,000, to maintain an electric light and power plant. Messrs. E. W. Gillett and N. E. Schmidt are among the directors.

LITCHFIELD.—Improvements are under way at the plant of the Litchfield Gas & Electric Company. New machinery is being installed, consisting of a 200-h.p. engine and boiler and a 150-kw. single-phase 1100-volt alternator.

PARIS.—The City Gas & Electric Company has filed articles of incorporation for the purpose of operating a gas and electric light plant. The capital is fixed at $150,000 and Messrs. A. J. Barber, W. J. Hunter and J. E. Parrish are the incorporators.

CARROLLTON.—Messrs. Robert H. Bigger, F. M. Sinsabaugh and W. D. Moore recently filed articles of incorporation for the Carrollton Heat, Light & Power Company, placing the capital stock at $5000. The company is organized to operate heat, light and power plants.

MORRISONVILLE.—The Morrisonville Electric Light Company, formerly owned by T. E. Cloyd & Son, has been incorporated under the style of the Morrisonville Electric Company. The capital stock of the company is placed at $6000. Messrs J. D. Lewis and T. E. Cloyd are among the directors.

RIDGEFARM.—The plant of the Ridgefarm Electric Light, Heat & Power Company, which was recently destroyed by fire, is to be rebuilt by Messrs. Henderson & Linn. Mr. W. Henderson was superintendent of the old plant. The old engine, which was damaged somewhat by the fire, is being repaired and orders have been placed for a new dynamo and a 150-h.p. boiler.

CARBONDALE.—The Carbondale Lighting Company has been consolidated with the Carbondale Water Works Company under the style of the Carbondale Water, Light & Power Company. The company has a capital of $200,000 and its officers are as follows: President, Mr. E. M. Kellogg; secretary, Mr. F. Mason; manager and purchasing agent, Mr. G. C. Campbell; superintendent, Mr. D. Fraser.

CHICAGO.—A proposition is being discussed whereby the city will receive the current to be generated by the water in the drainage canal at Lockport. Commissioner of Public Works Blocki states that 25,000 horse-power would supply an arc light for every street intersection in the city, which would be about three times the present number, and if the city can obtain this power the additional lights will be installed. The principal question under discussion is whether the power shall be given to the city at cost or whether a reasonable price shall be charged for it.

ALTON.—The merger of the Alton Light & Traction Company and the Granite City Electric Street Railway Company, which has just been effected, will unite several hundred miles of street railway and will connect Alton with St. Louis and intermediate points. The work of connecting the two systems of railways will be commenced at once. A proposition is being considered for increasing the capital stock of the two companies from $1,000,000 each to $3,000,000 jointly. The officers of the consolidated company are as follows: Mr. J. F. Porter, president; Mr. F. E. Allen, vice-president; Mr. C. A. Caldwell, secretary; Mr. J. H. White, superintendent. Lighting current will also be furnished to Upper Alton and North Alton, as heretofore.

CHICAGO.—On July 1 the City Council passed an ordinance providing for the issue of $5,000,000 bonds to be used for public improvements. Of this amount, about $1,750,000 has been appropriated for the extension of the electric light plant, bridges, fire and police stations, and other public work. Bids have been asked for by the City Electrician for furnishing and installing, where specified, the following for the use of the Department of Electricity: Two vertical cross-compound condensing engines of 1000 horse-power each, four water-tube boilers, three mechanical stokers and smoke consuming devices, mechanical induced draft apparatus, turbo-generator and direct-connected units and accessories, and 500 alternating-current enclosed-arc lamps.

INDIANA.

LEBANON.—A proposition to install an electric light plant here is being considered by the city.

KNOX.—Mr. Thos. A. Grist recently purchased the plant of the Knox Electric Light & Power Company.

MARTINSVILLE.—Plans are being prepared for a new brick power house for the Martinsville Light, Heat, Water & Power Company. The power house will be 50 ft. x 100 ft.

FORT WAYNE.—The Wayne Water Power Company has been incorporated with a capital of $100,000. Messrs. John H. Bass, John W. White and William A. Fleming are the directors.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

BERNE.—Articles of incorporation have been filed by Mr. H. H. Stucky, H. S. Michand and others, for the Berne Electric Light Company, in which the capital of the company is stated to be $6000.

JASPER.—Electric light bonds to the amount of $12,000 have been sold, and the contract for the power house and pumping station for an electric light plant and water system has been awarded to Schmidt & Renner, of this city.

ELKHART.—The Elkhart City Power Company has been incorporated by Messrs. C. G. Conn, P. L. Turner and W. I. Gronert, with a capital of $50,000. The company has been awarded the city lighting contract for ten years from August 1, 1904.

TERRE HAUTE.—Work on the new power house of the Terre Haute Electric Company is progressing and the boiler house is nearly ready for the installation of the three 520-h.p. boilers built by the Aultman & Taylor Company, Mansfield, Ohio.

MUNCIE.—Recent reports are to the effect that the plant of the Muncie Electric Light & Steam Heating Company has been purchased by The Electric Company of America. It is also stated that $150,000 will be expended in improving the property on North Walnut Street.

MARION.—The direct-current system now in use at the municipal lighting plant is to be replaced by a series alternating-current system. An alternating-current Westinghouse alternator is to be installed, also series enclosed arc lamps which will be run on four 75-light circuits. Mr. Otis Weesner is superintendent of the plant, and Mr. Charles A. Lower is chief engineer.

OXFORD.—The City Council is figuring on lighting two other small towns with electricity supplied by the municipal plant, one town being five miles and the other eight miles distant. In case the matter is acted upon favorably, a step-up transformer will be used for the most distant town with a transmission voltage of 6600 volts. Mr. H. E. Frost is now superintendent and chief electrician of the city lighting plant.

CRAWFORDSVILLE.—Some rather extensive changes are being made at the plant of the Crawfordsville Electric Light & Power Company. Larger units are being installed in the power house and the company is changing from 133 to 60-cycle circuits. The line wires now in use will also be displaced by wires of larger size. Mr. Spencer Stucky is chief engineer of the company.

ELKHART.—Mr. George R. Martin, who was formerly engineer at the power house of the Home Electric Company and who has filled various positions since he left here in 1900, has been appointed chief engineer of the Grand Falls plant of the Southwest Missouri Light Company, of Joplin, Mo. Mr. Martin resigned his position as superintendent of the New Albany (Ind.) water works to accept his present position.

BLOOMFIELD.—The Bloomfield Light, Heat & Power Company has been reincorporated and is now known as the Home Light & Water Company. The officers of the company, which is capitalized at $10,000, are as follows: President, Mr. R. B. Dugger, who is also manager and superintendent; secretary, Mr. John C. Gilliland; chief engineer, Mr. A. A. Howard, and chief electrician, Mr. E. H. Dugger. The company has the city lighting contract on a midnight schedule.

INDIAN TERRITORY.

COMANCHE.—The Comanche Electric Company, owned and operated by Diehl & Schneider, has been awarded the city lighting contract.

TULSA.—The Tulsa Water, Light, Heat & Power Company, of which Mr. John Dermott is president, has been incorporated with a capital of $120,000, and will proceed at once with the construction of its plant.

WAGONER.—The following are the officers of the Wagoner Light & Power Company: Mr. T. A. Parkinson, president; Mr. J. D. Brazell, vice-president; Mr. T. C. Harrill, secretary, manager and superintendent; Mr. H. E. Dodge, treasurer; Mr. S. D. Camp, chief engineer; Mr. C. E. Kapp, chief electrician.

IOWA.

PELLA.—The City Council may install a new electric light plant.

DUBUQUE.—The Union Electric Company proposes to extend its lines.

GREENE.—A project is on foot to organize a company to purchase a lighting plant.

HARLAN.—Mr. George W. Cox is now superintendent of the city electric light plant.

MOULTON.—Mr. L. L. Corey is chief engineer of the Moulton Electric Light Company.

HAWARDEN.—The electric light plant is to be extensively repaired at a cost of about $6000.

ORANGE CITY.—Mr. L. H. Slikkerveer is chief engineer of the Orange City Electric Light Company.

ROCK ISLAND.—Reports state that $5000 will be expended in improvements at the municipal lighting plant.

RICEVILLE.—The Riceville electric light plant is now owned by a stock company, of which Mr. Robert Templeton is secretary and manager.

AFTON.—The town authorities are planning to have the municipal lighting plant given a thorough overhauling. Mr. F. J. Spencer is manager.

BOONE.—The construction of a municipal electric lighting plant is being considered by the Town Council. It is estimated that the plant will cost $20,000.

SIOUX RAPIDS.—A committee has been appointed to secure the lowest price on the present electric light plant, which is owned by Mr. W. E. Brown, and also to ascertain the expense of putting in an entirely new one.

ROCK RAPIDS.—The City Council has decided that it is impracticable to rebuild the electric light plant this season. It will cost nearly $5000 to repair the present plant, using the same system, and it was deemed best to wait another year and install a modern system.

DES MOINES.—Recent reports state that the Iowa Light & Heat Company contemplates the construction of heating plants in University Place and on Pleasant Street, near Woodland, this fall, for which purpose an effort is being made to increase the capital about $50,000.

KANSAS.

ELDORADO.—Mr. W. M. Jones, of Rochester, N. Y., has the electric light franchise for this city.

HUTCHINSON.—The construction of an electric light plant has been recommended by the City Council.

OSBORNE.—A franchise has been granted to parties for the construction of an electric light plant here.

WINFIELD.—The citizens have voted to issue bonds for the purpose of constructing an electric light plant.

NORTON.—The advisability of constructing an electric light plant here is being considered by the Council.

CONCORDIA.—Messrs. O'Reilly & Dougherty, of this city, have been granted a ten-year franchise for furnishing the city with electric lights.

PITTSBURG.—The Pittsburg Gas Light & Coke Company is now known as the Pittsburg Gas & Electric Light Company. Mr. C. A. Patmor is superintendent of the plant.

IOLA.—The city has decided to extend the electric light service to the west side suburb. This will require the installation of additional equipment, which will necessitate enlarging the power house. Between $5000 and $6000 worth of new machinery has been ordered and bids have been asked for for the erection of an addition to the plant. Mr. I. E. Patterson is superintendent.

KENTUCKY.

PADUCAH.—Mr. Julius Fryout is now chief engineer of the municipal lighting plant.

PEMBROKE.—The Pembroke Water Power & Light Company has been incorporated with a capital of $10,000 to supply the town of Pembroke with electric lights and water.

OWENSBORO.—It is understood that the Council is perfecting plans for the immediate enlargement of the city lighting plant.

COVINGTON.—The City Council of Covington contemplates building and installing an electric light and power plant at a cost of $75,000. The plant is to be capable of supplying 350 arc lights and 150 32-c.p. incandescent lights.

OAKDALE.—The American Electric Lighting Company, which purchased the franchise to light the recently incorporated town of Oakdale, has filed a charter fixing its capital stock at $10,000. The incorporators are: Mr. Charles A. Hess, Miss Mary Rosenfield, Mr. Louis F. Ott and Mr. Thomas F. Condon. The franchise was granted for twenty-five years.

GEORGETOWN.—The following are the officers of the Georgetown Water, Gas, Electric & Power Company: President and manager, Mr. J. P. Jackson; vice-president, Mr. G. V. Payne; secretary and treasurer, Mr. J. R. Holzman; purchasing agent, Mr. J. A. Stanton; superintendent and chief electrician, Mr. S. F. Allen, and chief engineer, Mr. John Stone.

BARBOURSVILLE.—At a meeting of the stockholders of the Barboursville Electric Light Company, held recently, it was decided to be impracticable to continue the service in this city on the present basis. The company has made an offer to the town by which it agrees to put in a number of extra lights without increasing the cost, but to run the lights on a midnight instead of an all-night schedule. The town authorities are considering the proposition.

LOUISIANA.

VIDALIA.—Mr. L. A. Larson has been made superintendent of the new municipal lighting plant.

MACON.—The city has voted $12,000 for the purchase and improvement of the electric lighting plant here.

OPELOUSAS.—The City Electric Light Company expects to install a series alternating-current arc light system, which will necessitate the installation of more machinery.

OPELOUSAS.—Knox, George & Company, of New Orleans, have been selected by the City Council to make a full investigation of the operation of the water works and electric light plant, with a view to a general overhauling of the same and installing some new apparatus.

NEW ORLEANS.—The Interstate Electric Company, of this city, has been awarded the contract to wire and light the town of Woodville, Miss. Mr. Isaac G. Marks, manager of the contracting department of the company, states that the whole city will be wired and lighted and a power house built, making the task a large one.

MAINE.

BANGOR.—Mr. M. H. Rideough is superintendent of the city electric light plant.

CHERRYFIELD.—Mr. Frank C. Nash is now president of the Cherryfield Electric Light Company.

BELFAST.—The Belfast Gas & Electric Company will increase its capital stock from $100,000 to $115,000.

PITTSFIELD.—The Pittsfield Electric Light & Power Company is now owned by the Sebasticook Water Power Company, of which Mr. Allen Hackett is president.

CLINTON.—A charter has been granted to the Clinton Electric Light & Power Company, recently incorporated. Mr. F. L. Besse is president, and

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

Mr. M. Morrison, secretary and treasurer of the company.

BANGOR.—The Underwriters' Light, Heat & Power Company has been organized with a capital stock of $3,000,000. Mr. E. T. Nealy, is president of the company and Mr. Charles E. Dole, secretary and treasurer.

SEARSPORT.—The Searsport Electric Light Company has been organized by Messrs. Harry L. Cram and A. J. Desmond, both of Portland, for the purpose of manufacturing gas and electricity in Searsport. The capital stock is fixed at $10,000.

KITTERY.—The Arcadia Lighting Company has been incorporated with a capital stock of $100,000. Mr. E. L. Chaney is president and Mr. J. E. Forsyth, treasurer. Mr. L. H. Harriman and Mr. A. E. Knowlton are also among the incorporators.

GREENVILLE.—Articles of incorporation have been filed by the Greenville Light & Power Company, fixing its capital stock at $10,000. Mr. Charles D. Shaw, of this city, is president of the company. Work has been commenced on the power house and will be pushed as rapidly as possibly.

SOUTH ORRINGTON.—An effort is being made to interest the people in lighting their homes and places of business throughout the town with electricity. Negotiations have been opened with Bangor parties with a view to obtaining sufficient current for the purpose, and it is expected that the Council at its next meeting will make an appropriation for lighting the streets and public buildings by the same means.

ROCKLAND.—The following are the officers of the Rockland, Thomaston & Camden Street Railway Company, which has the lighting contract for the city: President, Mr. G. E. Macomber, of Augusta; vice-president, Mr. S. M. Bird, this city; secretary, Mr. H. M. Heath, of Augusta; treasurer, Mr. A. D. Bird, Rockland; manager, Mr. T. Hawken, Rockland; chief engineer, Mr. C. E. Gregory, Glencoe; chief electrician, Mr. George Gay, also of Glencoe.

MARYLAND.

ABERDEEN.—The Council has decided to expend about $8000 for the purchase or establishment of an electric light plant.

ROCKVILLE.—It is understood that the Council has decided to employ an engineer to prepare estimates for rebuilding or repairing the electric light plant which was burned several years ago.

TOWSON.—The County Commissioners have awarded to the Baltimore County Water & Electric Company the contract for supplying electric arc lights at Canton, Highlandtown and elsewhere at $90 a year for a term of five years and incandescent lights at $22.50 per year.

CUMBERLAND.—The Potomac Light & Power Company has been incorporated with a capital of $50,000 by Messrs. G. T. Blackford, George M. Botchford, William McL. Somerville, and others. The company offers to furnish the city free light for the City Hall and water works, and is asking for franchises.

BELAIR.—The Glencoe Power, Manufacturing & Supply Company has been organized for the development of water power and transmission of electricity, with Mr. C. A. Andrew as president and Mr. James T. Jones, secretary and treasurer. The company is authorized under its charter to generate and supply electricity for all purposes, also to build and operate steam or electric railways within the limits of Harford County.

MASSACHUSETTS.

WILLIAMSTOWN.—Mr. C. A. Roebuck is superintendent of the Williamstown Gas Company, which has the city electric lighting contract.

MILLIS.—The Town Council of Millis is considering the question of a three years' contract with the Medfield Electric Light & Power Company to furnish lights for the streets of that town.

INDIAN ORCHARD.—The contract has just been let for an electric light system and power plant at this point. The system will include a thousand incandescent lights and the power station will have a capacity of 1000 horse-power.

HUDSON.—Mr. William G. Lawrence, superintendent of the municipal electric light, has resigned his position on account of ill health, it is said. Mr. Lawrence has been in charge of the local plant for several years. He will be succeeded by Mr. J. C. Norcross.

LYNN.—The Lynn Gas & Electric Light Company has perfected plans for the placing of all electric wires except those used for the arc lights in underground conduits. Eventually the overhead system, with its poles and supports, will be supplanted by the essentials of a modern electric lighting system.

LANESVILLE.—Mr. Thomas H. Roberts, superintendent of the electric power plant here, states that the new machinery recently installed was considerably damaged by lightning a short time ago. The old engine was used to furnish power until the damage could be repaired.

MERRIMAC.—Work on the municipal light and power plant which is being installed in this city is progressing and the indications are that the plant will be in working order by September. About 200 of the proposed 400 poles have been set. There will be 300 lights which will light six miles of streets. It is estimated that the entire plant when complete will cost $11,000.

SUNDERLAND.—The Sunderland Electric Light & Power Company has bought what is known as the Munsell place in North Sunderland. A power house will be erected at the falls and a 45-h.p. Thomson-Houston generator will be installed. It is estimated that the plant will cost between $1200 and $1500, and it is hoped to have it in operation in a month or six weeks.

BOSTON.—The Universal Electric Corporation has filed articles of incorporation with a capital stock of $100,000. The promoters of the enterprise are Mr. Hiram P. Harriman, Wellfleet, president; Mr. N. Ellsworth Reed, Belmont, treasurer; Mr. Lewis E. Reed, Belmont, clerk, who, together with Messrs. George M. Palmer, Cambridge, and Hans Liebreich, of this city, constitute the board of directors.

HOLYOKE.—The Harbor & Land Commissioners have approved the plans of the Holyoke Water Power Company for the erection of a power station and the excavation of a raceway on the Connecticut River in Holyoke. The raceway will be about 600 feet long and 75 feet wide. The work will be begun as soon as detailed plans of the proposed station and appurtenances can be prepared and filed with the Board.

BEDFORD.—Electricity has been substituted for the old system of oil lamps for lighting the streets, and the Lexington Gas & Electric Company, of Lexington, has been awarded the contract to furnish current for incandescent lamps for a term of five years. Three miles of streets have been wired, the lamps being placed about 200 feet apart. The lamps will be lighted from sunset until 1 A. M., under what is known at the "dark-hour" schedule.

MICHIGAN.

EATON RAPIDS.—The citizens recently voted to issue water and lighting bonds.

ST. LOUIS.—Mr. R. W. Reading is superintendent of the St. Louis lighting plant.

WAUSAU.—The Town Council is considering a proposition to install a municipal lighting plant.

CLARE.—Mr. A. J. Doherty is now president and manager of the Clare Electric Light Company.

ALPENA.—The City Council is arranging to issue electric light bonds to the amount of $100,000.

ADDISON.—A vote is to be taken on the question of bonding the town for an electric lighting plant.

HOMER.—The Cortright Milling Company has the city lighting contract. Mr. W. H. Cortwright is manager.

MONROE.—Mr. William R. Goelliner is chief engineer of the municipal lighting plant, and Mr. F. J. Hill is chief electrician.

TRAVERSE CITY.—Bids are wanted May 31 for lighting the streets of the city for a period of five years from May 1, 1905.

PONTIAC.—The Council has advertised for bids for lighting the streets of the city by 136 arc lamps of 2000 candle-power each.

STANTON.—Mr. H. Busch is now superintendent of the municipal light and water plant, and Mr. C. F. Busch is the chief engineer.

ITHACA.—The citizens have voted to bond the village to the amount of $13,000 for the building and equipment of an electric light plant.

ROGERS.—Plans and estimates have been prepared for establishing an electric plant in Rogers for municipal and commercial lighting.

PORT HURON.—The Port Huron Light & Power Company has been awarded a five-year contract for lighting the streets of the city.

FLINT.—A new 300-h.p. boiler is to be installed in the plant of the Flint Light & Power Company, and a smokestack is to be erected 150 feet high.

SAGINAW.—Mr. W. A. Markey, of this city, has been selected by the City Engineer to assist in the preparation of plans for a municipal electric light plant.

PLAINWELL.—The Brownell Electric Company is investigating gasoline outfits, with a view to installing such a unit this summer to carry part of the load.

KALAMAZOO.—The Kalamazoo Electric Company will soon begin the construction of a power plant at Ceresco on Kalamazoo River, at an estimated cost of $200,000.

BUCHANAN.—The new electric light system has been completed and the town is again enjoying a complete lighting service. The streets have been in darkness since the first of last September.

PLAINWELL.—Bids have been called for for furnishing material and the electricity necessary to supply arc and incandescent street lights and arc and incandescent commercial and residential lights.

BEAVERTON.—The Beaverton Illuminating Company is owned by Ross Brothers. Mr. Ronald Ross is manager of the company; Mr. John Fitzgerald is superintendent, and Mr. William Sevier is chief electrician.

DETROIT.—The McCleary Electric Company has been incorporated with a capital stock of $10,000. Of this amount $6500 is said to have been paid in by the transfer of the McCleary & Colquitt Company's stock and fixtures.

ST. IGNACE.—This city has been left entirely without lights and fire protection, due to the destruction by fire of the water works and electric light plant, which was valued at $20,000. The plant will be rebuilt at once.

DETROIT.—The Peninsular Electric Light Company is making extensions to its three-phase power circuits. The company also lights the villages of Highland Park and Hamtramck. Mr. G. W. Cato is general superintendent.

BAY CITY.—The construction of a new municipal electric lighting plant, which has been under discussion for some time, is practically assured now. It is expected that a site on the river front will be selected for the new plant in order to obtain more power and secure better coal facilities.

BELLAIRE.—Reports state that Mr. Henry Richards, owner of the local power plant, is entertaining a proposition for the building of a 1000-h.p. plant here, to furnish a 24-hour alternating-current service and supply Charlevoix and other surrounding towns with current for lighting purposes.

GRAND LEDGE.—The Grand Ledge Electric Power Company has been incorporated by Mr. E. C. Jarvis, of Lansing, Mich., to acquire water power rights and build an electric plant for the purpose of supplying power to Grand Ledge and vicinity. The company's capital is fixed at $50,000. Messrs. Joseph H. Bootes and G. D. Smith, of Jackson, are also stockholders.

ALLEGAN.—The Allegan Light & Power Company, composed of Horace M. Olney, of Hartford, Mich., and A. B. Wilder, of Allegan, has sold its plant to Siebe Baker, Hiram A. DeLano and George E. DeLano, of Otsego, and Fenner M. Van Auken, of this city, who will continue the business under the same name. Current for domestic and commercial lighting and power purposes will be supplied as heretofore. The two plants here may be consolidated under the new management.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

MINNESOTA.

LANESBORO.—Mr. E. E. Lynch is superintendent of the Lanesboro Electric Company's plant.

FOSSTON.—Mr. John E. Domaas is superintendent and chief engineer of the village electric light plant.

THIEF RIVER FALLS.—It is understood that arrangements are being made to enlarge the city lighting plant.

LITCHFIELD.—Mr. E. Aveldson is manager and chief electrician of the municipal lighting plant of Litchfield.

STILLWATER.—The Stillwater Gas & Electric Company is contemplating the erection of a new power station.

ATWATER.—Village Recorder Larson writes that the citizens have voted to construct a water works system and an electric light plant.

RUSHFORD.—The City Council has advertised for bids for an engine, generator and material for an addition to the electric light plant here.

LITTLE FALLS.—The question of issuing $10,000 in bonds for building and equipping a lighting plant is under consideration by the Council.

SPRING VALLEY.—Mr. N. T. Cummings is now vice-president of the Spring Valley Electric Light & Investment Company, and Mr. G. M. Warren is treasurer.

ROYALTON.—The matter of establishing a municipal lighting system is to be submitted to a vote of the people. Plans and estimates of the probable cost of a plant are being prepared.

GRACEVILLE.—As the plant here is very much overloaded, the council is considering a proposition to increase the equipment by the addition of a 50-kw. unit. Mr. P. F. Daly is chief engineer and electrician.

DULUTH.—It is reported that arrangements have been made for the development of the water power of the St. Louis River. The contracts for equipment have not yet been made. Mr. C. A. Duncan, president, and Mr. C. C. Cokefair, general manager, of the Great Northern Power Company, are said to be interested in this enterprise.

MISSISSIPPI.

NEW ALBANY.—The City Clerk writes that an election is about to be held in connection with the matter of constructing an electric light plant.

MACON.—It has been voted by the citizens to purchase and refit the plant of the Macon Light & Power Company, and $20,000 in bonds have been issued for this purpose.

DELTA.—The Delta Electric Light & Power Company announces that it will immediately begin the work of extending its electric lines to take in all parts of the city.

OCEAN SPRINGS.—The work of installing an electric light system here has begun and will be pushed as rapidly as possible. There are to be arc lights at the street crossings. The company, it is said, has agreed to furnish lights for the churches and the town hall gratis if the necessary wiring is done by the parties interested.

LAUREL.—The officers of the Laurel Improvement Company, which has the contract for lighting the city, are as follows: President, Mr. S. M. Jones; vice-president, Mr. Edmund K. Stello, of New York City; secretary and treasurer, Mr. F. C. Harrington; superintendent, Mr. C. L. Williams; chief engineer, Mr. Benjamin Lee.

BOONEVILLE.—A franchise has been granted to local parties who have organized a stock company under the style of the Citizens' Light & Telephone Company, with a capital of $40,000, for the purpose of constructing a light plant and telephone system. Booneville has been without lights for some time and the new plant will be put in operation as soon as possible.

MISSOURI.

INDEPENDENCE.—Mr. J. T. Byars is superintendent of the city light plant.

BRUNSWICK.—Mr. William Steel is superintendent and chief electrician of the Brunswick water and light works.

ST. LOUIS.—The Suburban Electric Light & Power Company, of Webster Grove, St. Louis County, has filed a petition for a franchise to extend its lines over the county.

ST. JOSEPH.—An ordinance has been passed which provides for the issuance and sale of improvement bonds to the amount of $75,000 for purchasing a site and building thereon an electric light plant.

MEXICO.—Mr. W. F. Atkinson is now vice-president of the Mexico Electric Light, Heat & Power Company, succeeding Mr. J. W. Wooldridge. Mr. J. M. Howe is manager and chief electrician, and Mr. Morgan Day is chief engineer.

LEBANON.—We are advised of the incorporation of the Lebanon Electric & Power Company, with a capital of $2000, which proposes to construct and operate an electric light plant in Lebanon. Messrs. W. P. Simpson and W. I. Diffenderfer, of this city, are among the stockholders.

JOPLIN.—Work on the large power plant being erected by the Spring River Power Company at Lowell, Kan., is being pushed so rapidly that it is now thought the company will be in position by September 30 to furnish some power, although as previously reported, it will probably be a year before the plant is entirely completed.

MONTANA.

TOWNSEND.—The electric light plant of this place is now owned and operated by Bowhay Brothers.

LIBBY.—Mr. A. B. Johnson, of this city, has been granted a franchise for the establishment of an electric light plant and a telephone system.

RED LODGE.—The electric light plant of this place is now owned by the Northwestern Improvement Company. Mr. Robert Pettigrew is superintendent of the plant.

MISSOULA.—The Missoula Light & Power Company and the Missoula Water Company, of this city, have consolidated under the title of the Missoula Light & Water Company.

GREAT FALLS.—The present officers of the Boston & Great Falls Electric Light & Power Company are: President, Mr. John D. Ryan, of Butte, Mont.; secretary, Mr. J. C. Lalor, also of Butte; superintendent, Mr. E. I. Holland.

LEWISTOWN.—The Lewistown Electric Light & Power Company recently sold out to Bach & Cook, who have consolidated with the Citizens' Electric Light & Power Company. The plant has been greatly enlarged. The new company's capital is $50,000, and Mr. John Bright is president and manager.

NEBRASKA.

FALLS CITY.—Mr. A. Neitzel is at present superintendent of the municipal light plant.

SHELTON.—A new power house is soon to be erected by the Shelton Water Power Company.

OMAHA.—The citizens of this city are discussing the proposition of voting bonds for the construction of a municipal lighting plant.

STANTON.—The plant of the Stanton Electric Light Company is now owned by Mr. F. L. Sanders, formerly manager of the old company.

OAKLAND.—The proposition to issue $7000 in bonds for the construction of an electric light plant was carried at a recent election held for the purpose.

CRETE.—A new boiler is to be added to the equipment of the municipal electric light plant, of which Mr. Camel, of this city, is superintendent and chief electrician.

CHADRON.—The officers of the Chadron Electric Light & Power Company are as follows: President, Mr. H. H. Woodman; secretary, Mr. W. C. Walther; treasurer and manager, Mr. A. H. Savage; superintendent, Mr. R. B. McFadon; all of St. Paul, Minn.; and chief engineer, Mr. C. W. Reid, of this city.

NEVADA.

RENO.—The Washoe Power & Development Company has decided to place orders for all necessary equipment and machinery for its power plant, in order that the plant may be ready for operation in six months. Definite action is delayed pending the receipt of a report from the company's engineer.

RENO.—The Reno Power, Light & Water Company is engaged in the construction of two large reservoirs, the larger of which will have a storage capacity of 60,000,000 gallons and the smaller a capacity of about half that amount. The expense already incurred in construction work approximates $50,000, and the company plans the construction at some future period of another reservoir of still greater capacity. Bonds to the amount of $750,000 are to be issued by the company for the improvement and enlargement of the system.

NEW HAMPSHIRE.

WARREN.—An electric light plant is soon to be established here.

CLAREMONT.—The Claremont Railway & Lighting Company is arranging to increase its power equipment by the installation of an engine and boiler.

KEENE.—The following are the officers of the Keene Gas & Electric Company, which has a paid-in capital stock of $150,000: President, Mr. W. H. Elliott; vice-president, Mr. W. L. Mason; secretary and treasurer, Mr. G. M. Rossman, who is also manager and superintendent; chief electrician, Mr. W. A. Whitman. The company has the contract for lighting the city, supplying current for 55 arc lights of 1200 candle-power and 121 32-c.p. incandescent lights.

NEW JERSEY.

BOGOTA.—The Bogota Water & Light Company has filed a certificate increasing its capital stock from $10,000 to $20,000.

HACKENSACK.—Mr. E. C. Deal is now superintendent of the Hackensack plant of the Gas & Electric Company of Bergen County.

PATERSON.—The Public Service Corporation has secured the contract for lighting the streets at $101 per arc lamp and $18 per gas lamp.

WILDWOOD.—Mr. Frederick Sutton is now manager of the electric plant here, which is controlled by the West Jersey Electric Company.

SEA ISLE.—The stockholders of the Sea Isle City Electric Light, Heat & Power Company have disposed of their plant to the New Jersey Rapid Transit Company.

WEST HOBOKEN.—The contract for lighting the streets for a term of five years at $100 per arc lamp per year has been awarded to the Public Service Corporation.

WEEHAWKEN.—The Weehawken Construction Company has secured the contract for lighting the township with electricity for a term of thirty years at $90 a lamp per year.

PRINCETON.—The Princeton Lighting Company, which began operations last year, is a consolidation of the Princeton Electric Works, Princeton Gas Light Company and the Hopeville Electric Heat & Power Company. The Princeton Company also controls the Jamesburg Electric Light, Heat & Power Company and the Freehold Electric Light, Heat & Power Company. Mr. Charles P. Fitch is president and manager, and Mr. Robert Tynck is superintendent. The company has the city lighting contracts for seventeen towns. Extensive improvements are being made, which are still in course of construction.

TRENTON.—In increasing its capital stock from $10,000 to $4,000,000, the amended articles of incorporation of the National Gas, Electric Light & Power Company state that the company's object is to buy, acquire, lease, construct, develop, improve, maintain, operate and deal in and with properties, rights and franchises for or connected with the production and distribution of light, heat and power by means of gas, electricity or other agent. Mr. James T. Lyon is president and Mr. Frank K. Pelton, secretary. Among the other stockholders are Mr. Robert T. Gray, Mr. Theo. H. Eaton, Mr. E. L. Kelsey, Dr. J. B. Book, Mr. A. L. Stephens, Mr. F. M. Osborne, Mr. Charles W. Miller, Mr. E. T. Lynch, Mr. M. B. Dady, Mr. John D. McMahon, Mr. Ellwood T. Hance, Mr. A. D. Bennett and Mr. J. C. Duffield.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

NEW MEXICO.

CARLSBAD.—Messrs. William A. Finley and Matthew S. Grover are among the directors of the Public Utilities Company, which is making arrangements to construct an electric light plant and water works here.

TUCUMCARI.—The Tucumcari Water, Ice & Power Company, with an authorized capital stock of $25,000, recently commenced operations here, having acquired the plant and property of the Tucumcari Electric Light & Water Company. Mr. Alexander D. Goldenburg is president; Mr. L. E. Taylor, vice-president and engineer; Mr. A. S. Donoghue, secretary, treasurer and manager; Mr. J. H Laurie, Almagordo, superintendent. The company is contemplating the construction of water works and an ice plant in the immediate future.

NEW YORK.

BOONEVILLE.—Mr. George O. Bridgeman is superintendent of the village electric light plant.

GLENS FALLS.—Mr. E. A. Wakeman is superintendent of the Glens Falls Gas & Electric Light Company.

WATKINS.—Bids have been called for by the Board of Water and Sewer Commissioners for $20,000 electric light bonds.

FISHKILL-ON-HUDSON.—Mr. J. Donnelly is superintendent of lighting for the Citizens' Railway, Light & Power Company.

BALDWINSVILLE.—The plant of the Edison Illuminating Company, of this place, has been sold to the Seneca River Power Company.

LOCKPORT.—The shareholders of the Niagara, Lockport & Ontario Power Company have voted to increase the capital of the company from $1,000,000 to $10,000,000.

NEW YORK CITY.—The Twombley Power Company has been incorporated with a capital stock of $45,000. Among the directors are Messrs. W. I. Twombley and C. C. Dodge.

FULTON.—Mr. C. W. Tippy has resigned his position as manager of the Fulton Fuel & Light Company to accept one as superintendent of manufactures of the Rochester Gas & Electric Light Company.

ATTICA.—The plant of the Attica Electric Light Company was badly damaged by lightning a short time ago. All but two transformers on one circuit were blown out and all the arc lights were put out of service. The damage was repaired as speedily as possible.

POTSDAM.—Mr. J. Alguire, for some time chief electrician of the Potsdam Electric Light & Power Company, has been appointed manager of the company to succeed Mr. Heatley Green who recently resigned. Mr. Green has also resigned as director of the company and disposed of his stock.

CHATHAM.—The following are the officers of the Chatham Electric Light, Heat & Power Company: President, Mr. E. R. Coffin, Schenectady; secretary and treasurer, Mr. H. M. Francis, Schenectady; manager and chief electrician, Mr. J. F. Wilson; chief engineer, Mr. William C. Reed.

HEMPSTEAD, L. I.—A franchise for fifty years has been granted to the Queens Borough Gas & Electric Company, of Far Rockaway, conveying the privilege to string wires, erect poles and lay pipes along the county roads in the town of Hempstead for the supply of gas and electricity for lighting and heating purposes.

MIDDLEVILLE.—The Middleville Electric Light Company has been incorporated with a capital of $4000. The company will construct a plant for the generation of electricity to be used for light, heat and power purposes in Middleville, Fairfield and Herkimer. Messrs. Lewis H. Goodman and David E. Ford and Anna M. Goodman are among the directors.

NORTH ELBA.—Articles of incorporation have been filed by the Ausable Valley Light, Heat & Power Company, fixing the capital stock at $30,000. The directors named are Messrs. Wallace Murray, F. A. Gould, A. K. Botsford and C. F. Carpenter, of Saranac Lake, and Ernest Parker, of Keene. The company will operate in Keene, Jay, North Elba and Wilmington, Essex County.

PLATTSBURG.—Bids have been advertised for lighting the streets of the town for a period of five years from November 6 next, requiring 80 arc lights of 2000 candle-power each, or 60 arc lights of 2000 candle-power and 25 32-candle-power incandescent lights or their equivalent. The bids are to be submitted on a schedule until 1 A. M. and on a schedule from one-half hour after sunset until one-half hour before sunrise.

WESTCHESTER.—The employes of the local branch of the Westchester Lighting Company recently organized at the local offices of the company a branch of the Employes' Benevolent Association of the Westchester Lighting Company. Twenty-two charter members went into the organization, and the following officers were elected: President, Mr. James Boyan; vice-president, Mr. Albert Peffers; secretary and treasurer, Mr. Thaddeus Le Veniss. Delegations from the Mount Vernon and Yonkers branches were also present.

NEWBURG.—At the annual meeting of the Upper Hudson Electric Company, held in this city recently, the following officers were elected: President, Mr. L. F. Gillespie, of this city; vice-president, Mr. Eugene Wolf, of Athens; secretary, Mr. J. M. Sheehan, of this city; treasurer, Miss A. B. Hedges, Newburg. The company has electric light and power plants at Athens and Coxsackie, and not only furnishes power for those two villages, but also for New Baltimore, Coeymans and Ravena. Its territory extends from a point near the north line of the town of Catskill almost to Albany.

NIAGARA FALLS.—At a meeting of the directors of the Niagara Falls Power Company, June 23, the following officers were elected: President, D. O. Mills, New York; first vice-president, Edward A. Wickes, New York; second vice-president and treasurer, William B. Rankine, Niagara Falls; third vice-president, George W. Davenport, Niagara Falls; secretary, Frederick L. Lovelace, Niagara Falls; assistant secretary and treasurer, W. Paxton Little, Niagara Falls; executive committee, D. O. Mills, John Jacob Astor, Francis Lynde Stetson, Edward D. Adams, Charles Lanier, F. W. Whitridge, all of New York, and Victor Morawetz, of Philadelphia.

SPIER FALLS.—The Hudson River Water Power Company operates by means of power obtained from the Hudson River. Its equipment includes four 2000-kw. and two 2500-kw. alternating-current generators. The company furnishes 24-hour power service for the General Electric Company at Schenectady and the Hudson Valley Railway Company at Glens Falls and Saratoga. The current is transmitted over four circuits at 30,000 volts. Current for lighting purposes is supplied to Glens Falls, Saratoga, Ballston, Schenectady, Troy and Albany. Distribution is effected by means of six sub-stations located respectively at Glens Falls, Saratoga, Ballston, Alplaus, Watervliet and Albany.

WESTCHESTER.—An announcement of the purchase of the Westchester Lighting Company, which controls the electric lighting and gas lighting of a large portion of Westchester County, by the Consolidated Gas Company, is made, as it is understood that negotiations have been practically completed. The Westchester Company is capitalized at $12,500,000, $2,500,000 of this being 6 per cent. preferred stock. It has $3,999,000 of first mortgage 5 per cent. bonds. The Westchester Company was organized by the United Gas Improvement Company, of Philadelphia, and among the cities which it serves are Yonkers, New Rochelle, Mount Vernon, Pelham and White Plains. It owns valuable franchises, and its business has steadily increased with the development of Westchester County.

ADDISON.—Mr. F. H. Wheaton has disposed of his entire electric plant, including the poles and wires, together with his contract for lighting the streets of the village. Mr. J. F. Hubbs, of Hammondsport, who owns and controls several power plants throughout the State, is the purchaser. A new power house will be built to take the place of the one recently destroyed by fire. It will be a substantial brick structure and equipped with a double set of machinery capable of meeting all demands for lighting the streets, residences and business places of the village. Mr. Hubbs will submit a proposition to the Village Trustees to light the streets every night on an all-night schedule at an additional cost of $5 per light on the present yearly contract. It is expected that the plant will be ready for operation in about two months.

ROCHESTER.—A certification of consolidation of the Rochester Gas & Electric Company and the Rochester Light & Power Company, under the title of the Rochester Railway & Light Company, has been filed at Albany with the Secretary of State. The capital is $11,000,000, divided into 45,000 shares of preferred and 65,000 shares of common stock. The preferred stock is to bear 4 per cent. dividends for two years, and 5 per cent. thereafter. The directors are Frederick Cook, Alexander M. Lindsay, Edward Bausch, Albert O. Finn, G. A. Hollister, Thomas W. Finncone, George W. Archer, Henry A. Strong, Eugene H. Satterlie and Albert H. Harris, of Rochester; Henry D. Walbridge and Anton G. Hodenpyl, of New York City; Edward W. Clark, Jr., and Clarence M. Clark, of Philadelphia, and James Richardson, of Providence, R. I.

AMSTERDAM.—Representatives of the Hudson Valley Power Company, of Spier Falls, recently visited the Schoharie Falls plant of the Empire State Power Company of this city. It is believed that this visit is a preliminary to the absorption of the Empire concern by the Hudson Valley Company. It is the purpose of the latter company, in the event of the purchase of the Schoharie plant, to develop the water power of the river to the full extent and to operate the plant as an auxiliary to its large establishment at Spier Falls. In addition to serving Amsterdam consumers with electrical power from the plant of the present Empire State Power Company, it is stated that the construction of a transmission line is contemplated from this city to Spier Falls, so that in the event of temporary suspension of one plant power could be obtained from the other.

MECHANICSVILLE.—Considerable discussion has been aroused here by the report that it was the intention of the Hudson River Power Company, which operates the power plant below this village and at Spier Falls, to apply for a franchise to set poles and string wires in Mechanicsville for the purpose of furnishing electric power. Neither of the electric light companies now doing business here run a day circuit for power purposes, but the Mechanicsville Electric Light & Gas Company contemplates raising its dam at Willow Glen with this end in view, and the Halfmoon Light, Heat & Power Company is said to be negotiating with other parties for day power for the same purpose. For this reason, together with the fact that there are two telegraph companies, two telephone companies, two electric light companies and a trolley company, each with a set of poles on the public streets, the proposition to erect another set does not meet with favor by the citizens.

NORTH CAROLINA.

LEXINGTON.—Bids have been called for for the $61,000 bonds which the Council recently decided to issue for the construction of an electric light plant and water works.

OXFORD.—Water works and an electric light plant are to be constructed in this city by Messrs. Edward G. Frost, of Salisbury, and F. W. Siebert. The cost of the proposed plant is estimated at $60,000. The town has voted to pay the company $3500 annually for light and water service.

ASHEVILLE.—The W. T. Weaver Power Company, utilizing the power of the French Broad River at Asheville, is now supplying power to the Biltmore estate of Mr. Vanderbilt. The company has been successful in securing contracts to furnish power to a number of former steam plants in the city.

NORTH DAKOTA.

GRAND FORKS.—It is the intention of the Grand Forks Gas & Electric Company to expend about $20,000 in improvements.

OHIO.

GLENVILLE.—The City Council has advertised for bids for lighting the streets with electric lights.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

PROSPECT.—Mr. George Whysall is manager and purchasing agent of the Electric Light Company, of this city.

NILES.—The Niles Electric Company has been incorporated with a capital stock of $10,000. Among the directors are Messrs. F. W. Stillwagon and W. H. Smiley.

YOUNGSTOWN.—The power plant of the Youngstown-Sharon Power & Light Company is said to have been damaged by fire to the extent of $25,000.

SANDUSKY.—An ordinance has been passed granting the right to Mr. C. B. Dewitt to construct, maintain and operate an electric light, heating and power plant.

ROCKY RIVER.—The Rocky River Water, Light & Power Company has been incorporated with a capital of $75,000. Messrs. R. Fisher and C. Burkhardt are among the directors.

WARREN.—The Warren Water & Light Company, with a capital of $250,000, is a consolidation of the Warren Electric Light & Power Company and the Warren Water Company.

MANSFIELD.—Messrs. H. M. Byllesby and A. S. Huey, both of Chicago, have been elected president and vice-president respectively of the Mansfield Railway, Light & Power Company.

COLDWATER.—A franchise has been granted to Mr. R. C. Stueve, of Wapakoneta, to construct and maintain an electric light plant here. The franchise is for ten years and stipulates that operations shall begin not later than December 1 of this year.

SANDUSKY.—The following-named gentlemen have been elected officers of the Sandusky Gas & Electric Company: President, Mr. B. Mahler; vice-president, Mr. O. B. Wilcox; secretary, Mr. F. W. Coen; treasurer, Mr. A. L. Moss; general superintendent, Mr. A. C. Blinn.

McCOMB.—The McComb electric light plant, including all machinery and apparatus, poles and wiring for lighting the city, has been sold to Mr. William H. Frederick, of Bowling Green. Mr. Frederick virtually owned the plant and only bid it in in order to perfect his title. He is said to be negotiating for its sale with Mr. H. Mitchell, of Findlay, who was the only competitive bidder.

CINCINNATI.—The following contracts have been closed by President Norman G. Kenan, of the Cincinnati Gas & Electric Company, with the Westinghouse Company for a 1000-kw. motor-generator set, with the General Electric Company for 50,000 feet of covered cable feeders for use in underground conduits, and with the Standard Underground Cable Company for 100,000 feet of overhead wire.

MARION.—The officers of the Marion Electric Light & Power Company, which is a consolidation of the Marion Electric Light Company and the Marion Street Railway Company, are as follows: President, Mr. J. G. Webb, Springfield; vice-president, Mr. George S. Bright, Columbus; secretary, Mr. J. L. Vance, Jr., Columbus; treasurer, Mr. W. Guy Jones, Columbus; general manager, Mr. George Whysall; superintendent, Mr. R. E. Amman.

YOUNGSTOWN.—Mr. Albert Pabst, who was for eighteen years with the Youngstown Consolidated Gas & Electric Light Company as superintendent of the power house, recently resigned his position and will take a much needed rest, leaving shortly for a trip abroad. Mr. Pabst is succeeded by Mr. H. L. Patterson, who has been in the employ of the company for some time. Mr. Patterson, previous to his connection with this company, was with Sanderson & Porter, electrical construction engineers of New York City.

CINCINNATI.—A number of local interests are forming a company to undertake the work of utilizing for power and commercial purposes the Ohio River from Pittsburg to Cairo. The object is to construct a system of reservoirs at the headwaters of all the rivers and streams emptying into the Ohio along its entire length, thereby controlling the waters of the Ohio River. Another meeting of the projectors is to be held soon to decide whether the Government shall be requested to conduct the enterprise or whether it shall be carried out by private capital.

OKLAHOMA TERRITORY.

ALVA.—The Alva Light & Power Company is officered as follows: Mr. N. R. Gascho is president, manager and superintendent; Mr. R. P. Erwin is vice-president, secretary and treasurer, and Mr. L. D. Gascho is chief engineer and electrician.

OREGON.

ALBANY.—A franchise for the construction of an electric plant and telephone system in this city has been granted to Mr. W. D. DeVarney.

PORTLAND.—The Citizens' Light & Traction Company has been incorporated, with a capital of $200,000, by Messrs. A. Welch, O. Lowengart, Fred Langeman, Louis Sommer and M. Hoff.

SILVERTON.—A press report states that it is the intention of the Union Light & Power Company to expend about $50,000 in improvements at its water-power plant. Mr. A. B. Kurtz is superintendent.

MARSHFIELD.—Mr. F. M. Friedberg has sold his electric light plant to Mr. C. F. MacKenzie, of Colfax, Wash. The new proprietor intends to double the capacity of the plant and make other improvements.

GOLD HILL.—The Gold Hill Development Company, represented by Mr. H. Schaeffer, recently bought of J. J. Houck water power privileges for mining and manufacturing purposes, etc. It is the purpose of the company to furnish electric power for all purposes. It is expected that 8000 horse-power can be developed, for which purpose it will be necessary to construct a canal 2100 feet long, 50 feet wide and 8 feet deep with a 26-ft. constant head.

LA GRANDE.—The large Morgan Lake water power system, situated three miles south of this city on the summit of the Blue Mountains, which has been in course of construction by the La Grande Water Storage Company, is practically completed, and the storage company will soon be prepared to furnish the city with 75,000,000 gallons of water per month for distribution through the city water mains. In addition to this water will be supplied to a power plant, located one mile down the canyon from the lake, by means of steel pipe two feet in diameter. One thousand horse-power will be developed at first, the plant to have an ultimate capacity of 10,000 horse-power. The elevation of the lake above the city is 1450 feet in three miles. A lake 120 acres in extent and now averaging 12 feet in depth has been formed, with a possibility of increasing the depth to 30 feet by building a few hundred feet of levee.

PENNSYLVANIA.

NEW HOLLAND.—An electric light system is being installed here.

BROOKVILLE.—The construction of a new electric light plant is being discussed here.

LEWISTON.—The Lewiston Electric Light, Heat & Power Company is having plans drawn for a new power plant.

SHICKSHINNY.—Mr. J. Warren Briggs is superintendent and chief electrician of the municipal lighting plant of this city.

PHILADELPHIA.—The Frank M. Stewart Electric Company has filed articles of incorporation, placing its capital stock at $100,000.

CHAMBERSBURG.—Mr. S. M. Wheeler has been re-elected superintendent of the Chambersburg electric light plant.

WILLIAMSPORT.—New machinery is being installed in the plant of the Lycoming Electric Company, which will greatly increase its capacity.

COATESVILLE.—The incorporation of the Coatesville Consumers' Electric Light, Heat & Power Company, with a capital of $15,000, is reported.

ALLEGHENY.—The plant and stock of the Allegheny Light & Power Company have been damaged by fire to the extent of $35,000, according to recent reports.

NEW CASTLE.—Reports are to the effect that the Council will expend $8000 more on the extension of the municipal conduit system, which already has cost $60,000.

CRESSON.—Mr. W. A. Thomas is superintendent of the Cresson Electric Light Company, instead of Mr. D. P. Conrad, as stated in these columns last month.

READING.—A bill calling for a special election to obtain the assent of voters for a $200,000 loan for a municipal electric light plant was defeated in the Select Council.

DANVILLE.—The contract for the construction of the municipal electric light plant has been awarded to the Rumsey Electric Manufacturing Company, of Philadelphia, at $15,000.

PHILADELPHIA.—Recent reports are to the effect that Mr. J. H. Mack and associates are organizing a new electric light company capitalized at $8,000,000 to compete with the Philadelphia Electric Company.

FRANKLIN.—Messrs. O. C. Harris and D. W. Klinefetter, with others, are applying for a charter for the Franklin Electric Company, the purpose of the company being to supply light, heat and power in the borough.

WILLIAMSPORT.—Bids have been called for by the Light and Water Committee of the City Council for lighting the streets, city hall and several engine houses with either gas or electricity for a term of five or ten years.

MYERSTOWN.—Reports state that a representative of Lovegrove & Company, of Philadelphia, has been in this city recently with a view to organizing an electric light company. He solicited for half the stock, the remainder to be controlled by Lovegrove & Company.

NEWPORT.—Negotiations for the consolidation of the rival electric light companies of this city have been consummated and an agreement reached by which the Juniata Electric Company, in consideration of $26,000, purchases the plant and franchise of the Perry Electric Light, Heat & Power Company.

YORK.—The plan to establish a municipal lighting plant is being discussed by the Council. It is proposed to convert the crematory plant into a power house, instead of a municipal hospital, as has been suggested, and it is believed that favorable action in the matter will be taken shortly.

SLATINGTON.—At the annual meeting of the stockholders of the Citizens' Electric Light, Heating & Power Company, the following-named gentlemen were elected as directors for the ensuing year: Messrs. Fred Horlacher, E. D. Peters and Charles Benner, Jr., of this city, and Hons. Robert E. Wright and Hugh E. Crilly, of Allentown.

STROUDSBURG.—The erection of a plant at the Water Gap by the Delaware Water Gap Water & Power Company is being fought by local parties interested in a similar enterprise, who claim that the taking of water from the creeks would interfere with their rights. The company's plan is to combine the waters of Brodhead and Cherry Creeks, and it expects to erect a power plant at the Gap, where there would be a head of 100 feet of water, and furnish 5000 horse-power daily.

YORK HAVEN.—The York Haven Water & Power Company has issued $1,000,000 in bonds, which will be used for new equipment and extensions as they become necessary, the acquiring of additional property and such other needs as the growth of the company may require. The company is already engaged in the work of rebuilding that portion of its plant which was destroyed by the high water and ice several months ago. Work on the construction of the dam that is to furnish the water supply from the Susquehanna River has been resumed, and instead of erecting a temporary wall in the generating room for protection from the river, the company has had a strong brick river defence constructed.

SOUTH CAROLINA.

FORT MILL.—Mr. W. B. Moore, of Yorkville, is preparing plans for an electric light plant and system of water works to be constructed in this city.

LANCASTER.—The question of voting bonds for a municipal lighting plant is being discussed by the city. There is also talk of securing the power from a local cotton mill.

BATESBURG.—Bids are wanted for the $20,000 bonds recently voted for by the citizens, the

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

amount to be used for the purpose of installing an electric light plant and water works.

BELTON.—A charter has been applied for by Messrs. J. B. Adger, of Charleston, E. A. Smith, of Pelzer, and R. A. Lewis and J. T. Rice, of this city, with others, for the Belton Water Power Company.

CHARLESTON.—At the recent annual meeting of the Charleston Light & Water Company directors were elected for the ensuing year, with Mr. A. H. Post, president, and Mr. Zimmerman Davis, secretary and treasurer.

CHARLESTON.—Interests identified with the Charleston Consolidated Railway, Gas & Electric Company have chartered the Carolina Development & Construction Company, of Charleston, S. C., for the purpose of developing water powers in this State and the transmission of energy to manufactories. The company has organized as follows: P. J. Balaguer, of Charleston, S. C., president; E. W. Wynne, of Charleston, S. C., vice-president; F. K. Myers, of Charleston, S. C., secretary and treasurer; W. W. Fuller, engineer; M. Rutledge Rivers, of Charleston, S. C., general counsel; P. J. Balaguer, E. W. Wynne, B. A. Hapgood, W. G. Green, J. H. Dingle, J. Lamb Perry, C. F. Middleton, G. M. Politzer, F. K. Myers, directors.

SOUTH DAKOTA.

WILMOT.—The Town Council is considering a proposition to construct an electric light plant.

GROTON.—The Groton Light, Heat & Power Company has been organized with Mr. H. C. Miles as president and Mr. J. D. Jones, secretary. The company will erect its plant at once.

TENNESSEE.

CLARKSVILLE.—The Queen City Electric Light & Power Company proposes to install a new 150-kw., 1150-volt, 60-cycle monocycle generator and engine.

SPRINGFIELD.—The services of Mr. Granberry Jackson, of Nashville, have been secured by the town to prepare plans for the new water and lighting system. Bids will soon be called for.

DECHERD.—The Cumberland Oil, Light & Water Company has secured a franchise to furnish Decherd with light and water. Work on the necessary equipment will begin at once.

KNOXVILLE.—The Lighting Commission has presented a report to the City Council, in which it is recommended that the city build and operate its own electric light plant; also that a lighting committee be appointed by the Mayor with power to employ an expert electrical engineer to prepare plans and specifications for such a plant. It is estimated that the plant will cost about $137,000.

CHATTANOOGA.—Mayor Chambliss of Chattanooga has been making some interesting comparisons of the cost of lighting in cities which buy their light from private companies and those which own and operate their own plants. He recently called attention to the contrast afforded by the low cost per arc at which Nashville, which operates its own plant, is lighted as compared with the much higher price paid by this city. Chattanooga pays $85 per arc lamp, while the same service costs Nashville a trifle less than $50. Mayor Head, of Nashville, states that the total cost for lighting the city under contract had been about $49,000 per annum for 382 arc lights. On October 1, 1902, the city's new electric plant was completed at a total cost of $153,980.66, and the actual cost of operating the plant for twelve months was $35,162.96, which included interest on bonds, betterments, etc. The plant furnished 630 arc lights and 1961 incandescent lamps, as against the 382 previously furnished. After it had been decided to construct this plant, the private company voluntarily reduced its price to consumers from 18 to 12 cents per kilowatt, and contracts are now being made with the company for a term of years at 5 cents per kilowatt. The actual cost to the city, using its own plant, for producing electricity during twelve months was 2.65 cents per kilowatt.

TEXAS.

EL PASO.—The International Light & Power Company is installing a 500-kw. turbine in its power plant.

McKINNEY.—An $8000 bond issue has been voted for by the citizens to provide for the construction of an electric light plant.

ALVARADO.—The Alvarado Water, Light & Power Company has been incorporated with a capital of $40,000, by Mr. J. P. Parr, Mr. R. A. Messick, and others.

EL PASO.—The Suburb Gas, Light, Heat & Power Company was recently organized. The articles of incorporation fix the capital at $10,000 and Messrs. P. F. and P. J. Edwards are named among the directors.

TERRELL.—The Terrell Electric Light Company is extending its circuits to include some large plants which propose to utilize the current for power purposes. The company also controls the Kaufman Electric Light Company, of Kaufman, this state.

DENISON.—Mr. John R. Cullinane has resigned his position as secretary of the Denison Light & Power Company to assume the management of the Texarkana Lighting & Power Company. Mr. Cullinane had been connected with the Denison plant since 1886.

DALLAS.—The Dallas Electric Light & Power Company has perfected plans for the immediate erection in this city of a new power plant to cost when completed about $500,000. The constsuction work is already under way and it is expected that the entire plant will be ready for use within a year's time. A complete equipment of new machinery will be installed, the old steam engines now in use to be replaced by steam turbines. Mr. M. M. Phinney is general manager.

AUSTIN.—A proposition for the rebuilding of the dam across the Colorado River at Austin has been submitted by Mr. R. C. Deeming, of the Deeming Investment Company, Kansas City, Mo., and Dr. John M. Jacobs, of Lansdale, Pa., and is now under consideration by the city authorities. Messrs. Deeming and Jacobs offered to assume the bonded indebtedness of the city, amounting to $1,400,000, and to invest $500,000 in rebuilding the dam, water works and electric light plant, in return for a fifty-year water and light franchise from the city.

UTAH.

SALT LAKE CITY.—An Eastern syndicate, represented here by Mr. M. H. Boutelle and associates, has in view the purchase of the plant of the Salt Lake Water & Electrical Power Company, and with that end in view a postponement of the foreclosure suit against the company has been secured. The property is of considerable value, and if the purchase is consummated, an additional plant will be installed by the syndicate.

LEHI.—The directors of the Utah County Light & Power Company, consisting of Messrs. A. J. Evans, John C. Cutler, Sven L. Swenson, William H. Merritt, C. B. Harper, James H. Clark, S. L. Chipman and John Wotton, recently visited the company's plant at the mouth of American Fork canyon, for the purpose of inspecting the improvements just completed at a cost of $20,000. A location for another plant was also made and the president, Mr. Evans, was instructed to change the recent location decided on, so as to take the water from the creek at a point near Hanging Rock, about four miles up the canyon, whence it will be conveyed a short distance above the intake for the present plant. It is proposed to put in a flume 200 feet long, 6x6 feet, and then continue with a 3-ft. wooden pipe to the new plant, where two 1000-h.p. Pelton wheels will be installed. In the two miles of new pipe line there will be a fall of 569 feet, while in the old line, which is 1⅝ miles long, there is only a fall of 292 feet, and but 800 to 900 horse-power is generated at the old plant.

VERMONT.

MONTPELIER.—Mr. Edward P. Coleman is now vice-president and manager of the Consolidated Lighting Company.

BRANDON.—At the annual meeting of the Neshobe Electric Light Company, held here recently, the directors elected officers as follows: President, Dr. O. C. Baker; vice-president, Mr. Charles Dewey; treasurer, Mr. George H. McLeod.

ST. ALBANS.—The construction of the substation for the distribution of electricity to be transmitted from Fairfax Falls to this city by the Vermont Power & Manufacturing Company has been commenced upon the lot on South Main Street just beyond the city limits, recently purchased for the purpose. The work will be prosecuted rapidly and it is expected that the transformers and other machinery for the station will be set up and ready for operation very shortly.

VIRGINIA.

FRONT ROYAL.—Reports state that a bond issue of $15,000 has been voted for the purpose of constructing an electric light plant.

STUART.—The Electric Light & Power Company has been incorporated with a capital of $5000. It is the purpose of the company to have the plant in working order and the town lighted by September 1. Mr. John Axford is president, and Mr. E. J. Jarvey, secretary.

MARTINSVILLE.—The Town Council has purchased the water power at Hairston's Mill owned by Col. Peter Hairston. According to press reports, this purchase will insure either the partial or full development of the power at this point in the near future and the lighting of the town by electricity.

PETERSBURG.—A special meeting of the finance committee of the City Council was held recently for the purpose of considering the question of the city building and owning an electric light plant. The city pays annually to the Virginia Passenger & Power Company between $13,000 and $14,000 for electric lights for its streets and public buildings. There is a strong sentiment among the people and councilmen in favor of municipal ownership, and it is believed that favorable action in that direction may be taken in the early future.

WASHINGTON.

ELMA.—The City Council is considering the question as to whether it is advisable to grant a franchise for the construction of an electric light plant or to erect a municipal plant.

PALOUSE.—Mr. A Anderson is superintendent and chief engineer of the electric light plant owned by Mr. D. G. Klinefelter. Mr. George Emmett is chief electrician. Mr. Klinefelter has the city lighting contract for eleven years.

PROSSER.—Mr. E. F. Benson, of Tacoma, superintendent of the Prosser Falls Land & Irrigation Company, together with United States Senator Ankeny, will soon begin improving the water power at Prosser Falls with a view to securing several large factories here.

SEATTLE.—The syndicate of Syracuse capitalists who purchased the Seattle Lighting Company a short time ago has sold its interests, it is said, to a coterie of western capitalists headed by Mr. Charles G. Dawes, former controller of the currency and president of the Illinois Trust Company.

SEATTLE.—The Mutual Light & Heat Company is installing a 300-h.p. boiler with economizer and superheater. The company is now supplying heat for about 75 buildings. The officers are as follows: Mr. Charles E. Crane, president and manager; Mr. H. J. Clausen, vice-president; Mr. George Sackett, secretary and treasurer; Mr. H. R. Leigh, superintendent; Mr. O. H. Davis, chief engineer, and Mr. B. H. Leigh, chief electrician.

CHEHALIS.—A large portion of the town lights were out of commission for nearly a week recently, due to an accident to the machinery in the main plant. The crank shaft on the big engine broke and the cylinder head was blown out. Part of the lighting system is operated from the Chehalis Fir Gutter Company's plant, and this was the only current that was available for service until repairs at the main point could be effected. The plant is leased to Mr. Harry West, who has just been granted a franchise for another term of fifteen years beginning December 21, 1904. According to the terms of the lease Mr. West is to furnish the city with fifteen 2000-c.p. arc lights the first year, increasing gradually to twenty-four the fourth year; after that an arc light will be added for every increase of 300 in population, and thirty-one 16-c.p. incandescent lights are to be supplied free for the use of the city. The meter rate

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

is not to exceed 12½ cents per kilowatt-hour, with discounts for quantity and hours of light to make the rate as low as 6 cents per hour. The minimum charge for private service will be $1.00 per month. It is Mr. West's intention to move the plant to Littell, four miles west of town, where an abundant supply of cheap fuel can be obtained.

WEST VIRGINIA.

RICHMOND.—The Richmond Light & Power Company has been incorporated with a capital of $25,000, to construct an electric light plant, ice factory, grist mill and pop factory. Mr. R. M. Dyer is president.

WISCONSIN.

MELLEN.—There is said to be a good opening in the village for a light and power plant.

RHINELANDER.—A 20-year franchise has been granted to the Rhinelander Lighting Company.

NORTH FON DU LAC.—The village is to be bonded for the construction of an independent lighting plant.

WAUSAU.—The construction of an electric light plant, to cost $33,000, is under consideration by the Council.

JANESVILLE.—The Council has passed an ordinance requiring that electric and telephone wires be placed underground.

BERLIN.—City Clerk Henry Morman writes that no bids were received on July 1 for lighting the city for a period of ten years.

WAUSAU.—A new water-power plant is being built and equipped by the Wausau Electric Company, of which Mr. M. Weeks is superintendent.

MENOMONEE.—Mr. W. G. Patterson has been elected manager of the Menomonee Electric Light & Power Company; Mr. T. B. Wilson is president and Mr. Alex. Hosford is secretary.

BURLINGTON.—The Burlington Electric Light & Power Company is contemplating improvements at its plant to consist of a 100-hp. engine, a 250-hp. boiler, feed-water pump and heater.

NEILLSVILLE.—The Neillsville Light & Power Company has recently been incorporated with Mr. M. J. Foot and Mr. S. M. March among the directors. The capital of the company is stated to be $20,000.

WARREN.—The lighting plant for the town is operated in connection with the manufacturing business of the George Warren Company, who furnishes current for a few private houses, the public buildings and street lights.

BELOIT.—The Beloit Electric Company has been awarded the contract for street lighting for a term of ten years at $65 per light per year for 100 lights to burn until 1 o'clock and $85 per light per year for ten lights to burn all night.

MENOMINEE FALLS.—A company is being formed for the purpose of erecting an electric plant here. Mr. F. C. Kehr, a young electrician of this place, is said to be interested in the promotion of the project. It is expected that ten arc lights will be furnished for the streets, and about 1000 incandescent lamps are already secured.

MINERAL POINT.—The officers of the Mineral Point Electric Light Company, formerly known as the Mineral Point Zinc Company, are as follows: President, Mr. D. B. Jones; vice-president, Mr. T. D. Jones; secretary and treasurer, Mr. W. A. Jones; manager and superintendent, Mr. H. S. Weil; and chief engineer and electrician, Mr. W. A. Sherman.

MILWAUKEE.—At the request of the Board of Aldermen, City Comptroller Peter Pawinski has prepared a statement showing that the cost of lighting the streets and certain public buildings during 1903 was $256,564.14. Of this amount $166,737.73 was for electric lights, $75,494.78 for gas, and $14,313.62 for gasoline lights. The purpose of this report is to show what it costs the city for light, the data to be used in a campaign for a municipal plant.

STEVENS POINT.—The Stevens Point Power Company, in which Mr. William Mainland, of Oshkosh, and Mr. Sinclair Mainland, of Green Bay, are said to be interested, recently filed articles of incorporation at Madison, stating the capital stock to be $100,000. The company will operate a water power on Wisconsin River. The property which has been secured contains 175 acres and there is a saw and grist mill on the land. A new dam is to be constructed which will give increased power, and it is expected that most of the power will be utilized at Stevens Point.

KENOSHA.—Mr. Fred W. Bowen, who for several years had occupied the position of secretary and general manager of the Kenosha Gas & Electric Company, has severed his connection with the company to accept a position in some western city, it is said. Mr. Bowen has been closely connected with the building up of the electrical industry in Kenosha, since coming to this city from Milwaukee eight years ago. He was largely interested in the installation of the new lighting system, and when the company was reorganized it was in accordance with plans formulated by Mr. Bowen. Mr. Roger N. Kimball, who is scheduled to succeed Mr. Bowen, has been connected with the business of the company for the past three years, having been closely associated with Mr. Bowen during that time.

WYOMING.

DOUGLAS.—The Douglas Light Company, which has been operating for about a year, has the contract for the city lighting on an all-night schedule. The company has a capital stock of $20,000 and is officered as follows: Mr. J. T. Williams, president; Mr. John Morton, vice-president; Mr. E. J. Swan, secretary and treasurer; Mr. F. E. Johnson, manager and superintendent.

CANADA.

NEWMARKET, ONT.—A small direct-connected unit is being installed at the municipal electric plant to carry the incandescent load after midnight.

ALVINSTON, ONT.—The Alvinston Power Company has been incorporated by Mr. A. S. Harkness, Mr. D. C. Munroe and others. The company is capitalized at $40,000.

TORONTO, ONT.—The Toronto & Niagara Power Company is arranging to erect a large fireproof sub-station on Davenport Road, bids for which have been called for.

WOODSTOCK, ONT.—It is said to be the intention of the Woodstock Electric Railway, Light & Power Company to develop a water power on the Meduxnakik River about two miles from this town.

NIAGARA FALLS, ONT.—Mr. Charles C. Egbert has been appointed mechanical engineer to superintend the erection and installation of the 10,000-h.p. turbines to be used in the wheel-pit of the Canadian Niagara Power Company.

VANCOUVER, B. C.—The British Columbia Electric Railway Company, Ltd., is changing to water power and will probably develop 30,000 horse-power, of which 3000 has already been installed. The power will be transmitted twelve miles at 20,000 volts. Mr. R. H. Sperling is superintendent of the company, and Mr. W. V. Hunt, assistant superintendent.

HAMILTON, ONT.—The City of Hamilton is making an effort to get cheaper street lighting. It now pays $85 a lamp per year, which is the highest price paid in any city in the Dominion. A clause in the present contract specifies that at the end of August, if it can be shown that the cost of producing light has been reduced since the signing of the contract five years ago, the city will then be entitled to a reduction in the price of street lighting. The city engineer figures that the cost has been reduced at least $15 per lamp by the new enclosed arc lamps alone.

KINGSTON, ONT.—On July 1 the city contract with the Kingston Light, Heat & Power Company terminated. The city will probably enter action against the company for specific performance and for possession of the plant. By arbitration the city was ordered to pay $170,000 for the electric and gas plants of the company, but the company wanted the city in addition to care for $100,000 bonds to run for thirteen years. These bonds call for 5 per cent., while the city can get money at 3 per cent. The city offers its bonds in exchange at 3 per cent., but the bondholders demur. Until the city gets possession of the plants, the streets will remain in darkness.

SHAWINIGAN FALLS, QUE.—Mr. Julian C. Smith is superintendent and operator of the plant of the Shawinigan Water & Power Company, which is one of the largest and most important power plants in the Dominion of Canada. Mr. Wallace C. Johnson is chief engineer of the company. Current is transmitted to Montreal, 85 miles distant, and to other points nearer by, for power and lighting, the operation of railways and the furnishing of power for electrochemical industries. Six thousand horse-power is now being delivered in Montreal. A second transmission line of 10,000 horse-power capacity is under construction and the amount of power delivered is to be greatly increased within the next few months. Other large power units have been arranged for at the Shawinigan Falls plant, and the new water wheels to be installed will be of 10,000-h.p. capacity, each driving a 6600-kw. generator; the wheels now in use are 6000-h.p. machines. At present the plant is capable of developing 25,000 horse-power.

MEXICO.

JIMINEZ, CHIHUAHUA.—Electric lighting and telephone systems are to be installed here, the contracts for which have been awarded to Weisel & Kok, of Parral, Mexico.

SAN LUIS POTOSI.—Dr. Paschal, Mr. W. Schuwirt and Mr. H. Garcia, of San Antonio, Texas, are reported to be interested in the establishment of an electric light and power plant in this city.

TEPIC, TEPIC.—Advices state that the owners of the Jaupa cotton mills are arranging to furnish this city with current for lighting purposes. The city has a population of 15,000 persons, and it will be necessary for the company to install considerable new generating equipment.

ZAJOTITLAN, PUEBLA.—Mr. Frank Brennan, of Mexico City, has applied for a concession which will permit of the utilization of the fall in the River Atoyac or Santa Maria Tepezintla, located in the District of Zacatlan, at a point about nine miles distant from this city. The franchise permits the use of 1500 liters of water per second, the power thus obtained being intended principally for lighting purposes.

MEXICO CITY.—The canal and tunnel for the Atlixco Light & Power Company has been completed and the plant will be ready for operation as soon as the pipe line, now in course of construction, is finished. The pipe line leading from the mouth of the tunnel will have a drop of 135 feet, and the supply of water thus obtained will generate 750 horse-power. The entire cost of the work is estimated at $150,000.

MEXICO CITY.—An order has been placed by the Mexican Light & Power Company, of Montreal, Canada, for 1500 miles of cable weighing 4,200,000 pounds, to be used on the Necaxa-Mexico City-El Oro power transmission line now in course of construction. This cable will be supported on steel towers in spans of 500 feet. The process has been patented and will supply all the power for the City of Mexico.

PUEBLA, PUEBLA.—The City Council of Puebla has extended the contract with the Compania Anonima del Alumbrado Electrico for furnishing lighting current to the city for a period of 25 years on condition that the capacity of the plant be increased and the free service of 200 arc lights be established. The company operates a water-power plant of about 500 horse-power capacity. Mr. H. S. Wilson is superintendent and chief engineer of the plant.

IGUALA, GUERRERO.—Jose Maria Volasquez and Miguel S. Macedo, of Mexico City, have received permission from the Mexican Government to establish an extensive electric power and irrigation system in the Iguala District. Power will be obtained from the Tuxpam, Lagoon, Tubpam and Amates Rivers. Application has also been made for the necessary concession from the Mexican authorities for the use of 20,000 liters of water per second from the Tomatal River, this state, for the operation of an hydraulic plant for lighting purposes chiefly.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

American Electrician.

Vol. XVI. New York, September, 1904. No. 9.

A PROGRESSIVE WESTERN TELEPHONE EXCHANGE.

NEW TELEPHONE EXCHANGE AT BOULDER, COLORADO.

BY H. K. SPRAGUE.

THE Colorado Telephone Company has recently completed and is now occupying a handsome new two-story building at 1327 Spruce Street, Boulder. The company had entirely outgrown its former quarters in the Masonic Temple Building, and felt the necessity not only of moving but of changing its equipment from the old-style of magneto office to the common-battery central-energy lamp signal apparatus now in vogue in the most advanced practice of the companies affiliated with Bell interests. In the new building are located the company's largest exchange in the country just north of Denver and the local business offices for the management of all the telephone traffic in Boulder and its vicinity.

The structure, which is known as the "Telephone Building," is a two-story and basement building with ground dimensions of about 60 by 30 feet. The walls are of Boulder brick, and the trimmings, Fort Collins red sandstone, the construction being of the mill type with steel reinforcement in the floor supports. An alley on the east side leading to the rear yard enables supplies to be readily brought into the store sheds by teams. The building faces the principal park in the city and is most picturesquely located, the foot hills of the Rocky Mountains lying within two or three miles of the site. All openings in the floors are surrounded by metal sheathing projecting at least 2 inches above the floor, so arranged that if the floor is flooded the cables will be protected from water flowing down between the sheathing and the floor.

The basement contains the distributing apparatus of the office, storage battery and other features which will be described later. On the first floor are the general offices, public office containing three sound-proof telephone booths for toll work, a table with newspapers, and comfortable chairs for patrons waiting for calls, public operator's desk, agent's office, toilet room, storage closets and foreman's office. The second floor contains the main operating and retiring rooms, and above it is a low attic and trap door leading to the roof. The building is heated by an Ideal sectional hot water heater connected with the chimney by a galvanized iron smoke pipe. The architect for the building was Watson Vernon, of Boulder. A notable feature is the large number of windows provided, the basement

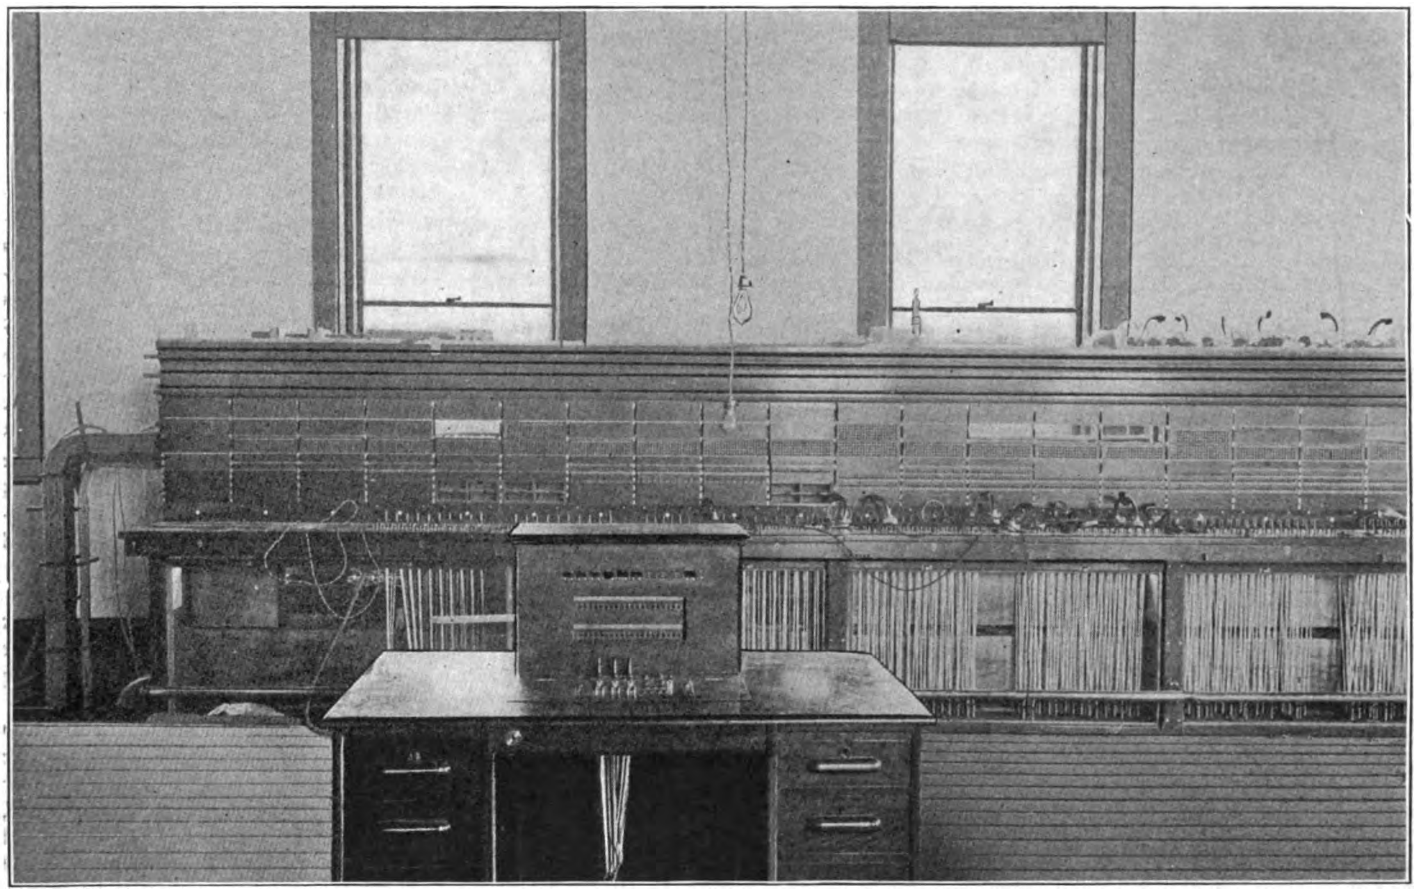

FIG. I.—TELEPHONE SWITCHBOARD OF THE COLORADO TELEPHONE COMPANY AT BOULDER, COLO.

being especially well off in the matter of daylight.

All telephone wires enter the building by four 200-pair lead-covered underground cables on the south or Spruce Street side of the basement. These cables then pass to the main distributing frame in the basement, the conductors spreading out and running up the vertical racks to the carbon protectors and heat coils. Metallic circuits are used throughout, each side of the line being protected with a carbon lightning arrester and a heat coil.

Eight shelves, with 140 pairs of terminals per shelf are provided on the horizontal side of the main distributing frame, while the vertical side has a capacity of 7 arrester bars with 100 pairs of arresters per bar. Maple channel strips for 1120 total pairs of terminals are installed on the horizontal side of the frame. The local circuits are equipped with Western Electric No. 41 heat coils, about 4 ohms each, and the toll lines with No. 4 heat coils of 40 ohms each. This frame is arranged to be extended to a capacity of 16 arrester bars. The first bar is set apart for toll lines and outgoing trunks, the remaining bars being used for subscribers' lines.

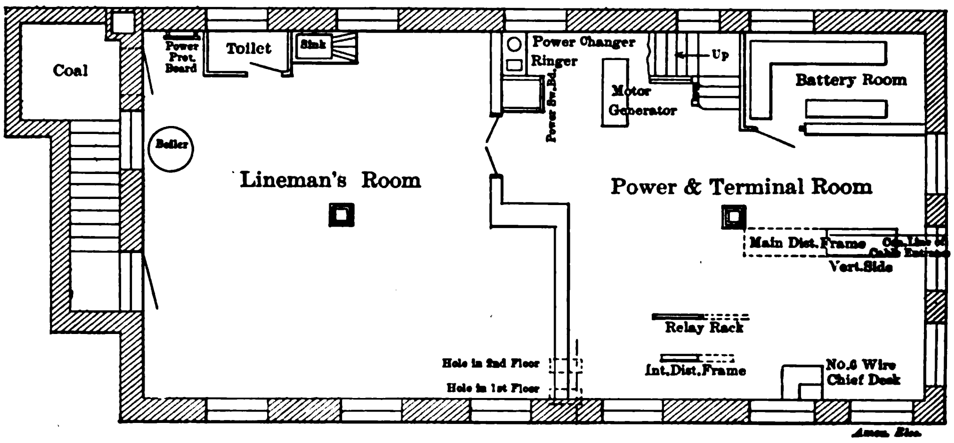

FIG. 3.—PLAN VIEW OF BASEMENT OF BOULDER TELEPHONE BUILDING.

From the verticals, the circuits are carried to the horizontal side of the frame, and there combined into 20-pair flat cables, in which form they are carried to the intermediate distributing frame. The capacity of the horizontal side of this frame is eight shelves of 100 lines per shelf, while the vertical side has five bars with a capacity of 160 lines per bar. The toll and trunk lines are mounted to allow a maximum possible growth of subscribers' lines. Adjoining the intermediate distributing frame is the relay rack, with a capacity of 800 relays. The first installation included 580 relays for subscribers' lines, 21 for toll lines, and 20 for the outgoing trunks. The subscribers', outgoing trunk and toll line relays are numbered to correspond to their associated line lamps. All of the telephone apparatus is built in conformity with the latest and most approved practice of the Western Electric Company, of Chicago. A fuse board is mounted on the frame which supports the relay rack to protect the operator's cord circuits, supervisory lamps, etc. The fuses are so arranged that when one blows a spring makes contact with a third bus-bar, ringing an alarm bell to call the attention of the trouble man. An inspector's testing table stands in the distributing room near the main distributing frame. It has one inspector's position, one cord circuit, two test line circuits to the switchboard, three in-coming trunk lines, and two trunk line circuits to the main frame. There are also a testing voltmeter, with a shunt key to reduce its resistance from 10,000 to 196 ohms for measuring low resistances, and keys for testing grounds, continuity, crosses, capacity, foreign currents, earth potentials and switchboard troubles.

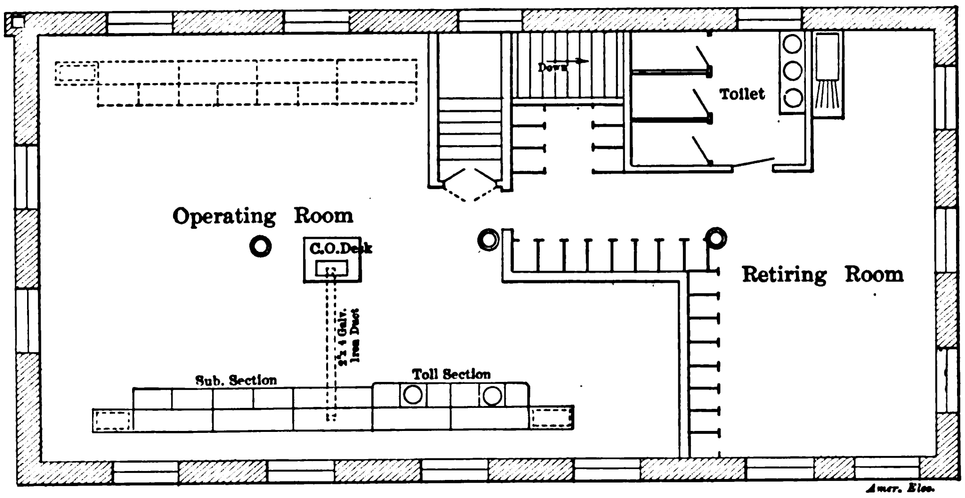

FIG. 2.—PLAN VIEW OF OPERATING ROOM OF BOULDER TELEPHONE EXCHANGE.

The power installation consists of a one-panel switchboard, a power protection panel, a Western Electric 25-ampere 36-volt generator direct-connected to a 2-h.p., 110-volt direct-current motor, a 16-cell storage battery, ringing machines, etc. Power is regularly obtained from the 110-volt lines of the Boulder Light & Power Company. The 110-volt alternating current of the same company enters the telephone building at the attic level on the north side, and supplies the incandescent lamps throughout the offices. Rubber-covered wire is used throughout the building. The ringing dynamotor is a 35-watt Western Electric machine, with a 110-volt primary and a 75-volt secondary. The power switchboard consists of a single slate panel mounted in the distributing room. It contains one Jewell volt-ammeter, baby size, ampere scale 0 to 50, central zero, volt scales 0 to 50 and 0 to 5, a 45-ampere single pole underload I. T. E. circuit breaker, five switches, a generator field rheostat, two starting boxes, one 200-ampere fuse, a 35-ampere fuse, two 2-ampere fuses for the pole changer, two 25-ampere D. & W. fuses for the charging generator, two similar fuses for the charging motor, and two 4-ampere fuses for the ringing dynamotor. The pole changer is a Warner machine, and it runs at night time after the dynamotor has been shut down. It is located on the same shelf as the dynamotor. There is also a power protection panel in the building near the point where the 110-volt direct-current circuit enters. It contains one double-pole, single-throw switch, two 30-ampere D. & W. fuses, two General Electric M. B. telephone-type lightning arresters, and four Western Electric reactance coils. The storage battery consists of sixteen of the Electric Storage Battery Company's type "F-11" chloride accumulators set on a special cupboard in a small battery room just off the main distributing room. The battery room is about 13 ft. long by 6 ft. 8 ins. wide, and the discharge rate of the cells on the 8-hour basis is 50 amperes. Glass tanks are used, set in trays filled with sand. Adjoining the terminal room is the linemen's room, containing the heater and various shelves for storage purposes.

From the relay rack the three-wire telephone circuits pass up through the general office floor to the main operating room by an enclosed wooden cable way. The operating room is 40 ft. 4 ins. long and 27 ft. 2 ins. wide for most of its length. At the east end of the room is a stairway leading to the street floor.

The main or subscribers' switchboard is located in straight sections on the west side of the room. It is a standard local relay, multiple, central-energy, lamp-signal board, Western Electric Company's No. 8 pattern, and consists of five 5-panel two-operator sections. Each section is 5 ft. long, the toll portion of the board occupying a space 10 ft. in length, and the local or subscribers' section, a space 15 ft. long. The total length of the switchboard, including the cable openings at each end, is 30 ft. 4 ins. A passageway 2 feet wide extends the entire length of the board on the wall side.

The ultimate capacity of the board is 1500 lines and 200 outgoing and local trunk multiple jacks. The operating installation covers 600 subscribers' multiple jacks, 40 toll and recording trunk multiples, 40 outgoing and local trunk multiples, and there are 100 answering jacks in use per subscribers' position, 200 being the ultimate capacity. There are 7 answering jacks per toll operator's position, 580 total subscribers' answering jacks, 21 toll line answering jacks and 20 two-way trunk jacks. Fifteen subscribers' cord circuits are installed per position, this being the ultimate capacity of the board. There are four through cord circuits for each toll operator's position, and six local cord circuits. There are also provided four local switching trunks, two test line circuits and one instruction circuit. The night bell circuit is mounted in the rear of the third section of the switchboard. Enough jacks are provided in the trunk multiple for 20 outgoing trunks. A key is also supplied to throw the last toll and first local positions together for night work. Enough cable is provided to enable the present No. 8 board to be replaced by a Western Electric No. 1 board when the growth of traffic requires it. The No. 1 board is the type used in the company's main office in Denver, and has a capacity of 9600 lines; it is called an "A" or subscribers' operators' board, and incoming trunking is done over a separate or "B" board. Space for the installation of a "B" board and a toll board is provided at the east side of the Boulder operating room. The subscribers' lines and direct recording trunks are multipled at all toll sections, and the toll lines themselves are multipled also. All exposed woodwork on the front of the switchboard is mahogany.

In the center of the operating room is the chief operator's desk. It is equipped with one operating position, three local cord circuits, four trunk circuits, four local switching trunk circuits, ten monitor circuits to the switchboard, and one instruction circuit. This desk is equipped for two-party line ringing. The chief operator's principal duties are: general supervision of the operating and operating room force; distribution of operators' loads; answering requests for charges; handling inquiry and duplicate calls; handling "appointment" and "leave word" calls; handling complaints, and the distribution of through calls. No supervisor's stands are provided, the exchange not being large enough to require the service to be watched by more than one supervising operator. At the right of the chief operator are two card indices. One index contains the names and addresses of subscribers, arranged numerically according to their telephone numbers. The other index is frequently not found in even large telephone exchanges. It is indexed alphabetically by streets and numerically by street numbers under the different subscribers' stations. This index is used to supply information as to the name or telephone number of a party living at a certain address. The company has many calls a day from people who have remembered the addresses of subscribers but who have not in mind the person's name or his telephone number. The company's ability to supply this information has been a great convenience to subscribers. There is also the usual alphabetical telephone book at the chief operator's desk, kept up to date by pencil insertions through the quarter years. Often a subscriber desires to find out the nearest telephone to a certain street number which has no telephone itself, and the index furnishes this information at a glance. The index was, however, not equal to the recent request of a subscriber who desired a connection with a party, name, telephone number and address unknown, "who lived in a yellow house on Blank street." Perhaps if the cards had been colored to correspond with all the shades and tints of a mile or two of different residences the subscriber's lapse of memory might have been overcome without the unwarrantable delay of repeating every name and number on the street. Many fire alarm calls in Boulder are given through the telephone office.

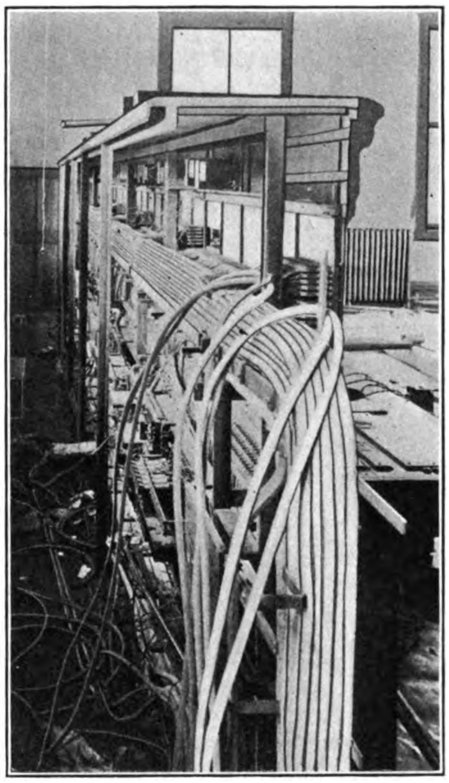

FIG. 4.—REAR VIEW OF TELEPHONE SWITCHBOARD.

The handling of toll calls is an interesting feature of the Boulder exchange. When the subscriber wants a long-distance connection he removes the receiver from its hook; the "A" or subscriber's operator at the local station of the board plugs into the subscriber's answering jack and asks, "Number?" The subscriber asks for a toll connection, and the "A" operator tests the small bank of recording trunks which form part of her trunk multiple, and selects an idle trunk. In its jack she inserts the other plug of a pair of cords, thus lighting a calling-in lamp at the recording toll operator's position and connecting the subscriber with the toll section of the switchboard. The toll operator answers her signal lamp by plugging in with one cord of a pair, and finding the subscriber on the line, records his call. Just before the completion of the recording, and incidental to it, the toll operator checks the number given to her by the subscriber, taking it up on another cord in the multiple before her, using this new line of connection in repeating to the subscriber the information which she has placed upon the ticket. Any error in number must at once be discovered in this way, after which the second cord is disconnected. The toll operator then tells the subscriber that he will be called as soon as the connection is completed, after which the subscriber "hangs up" his telephone, lighting the supervisory disconnect signal at the "A" position. The toll operator finishes writing the ticket and then removes the answering plug from the original recording trunk, thus setting the second supervisory signal at the "A" position. This signal is treated by the "A" operator as a peremptory disconnect signal, even if the subscriber prevents the disconnect signal, etc., from lighting by removing his telephone receiver from its hook or leaving it unhung. The "A" operator then clears the original connection. Upon the completion of the call, the toll operator plugs into the subscriber's jack in the multiple before her, and calls him, stamping the ticket with a calculagraph at the beginning and end of the conversation. At the end the toll operator disconnects. All inward calls from outside exchanges are completed directly in front of the toll operator in the desired subscriber's multiple jack.

On the second floor is also the operators' retiring room, containing lockers, couches, easy chairs and a gas heater for making coffee. There is a well-appointed toilet room adjoining the retiring room.

As regards fire risks, the building is in excellent condition. There are very few dark corners; oil is stored in small quantities outside the building; water faucets are located in the east and west walls on the outside, and the electric wiring is very carefully done. "Swan" dry powder fire extinguishers are hung in conspicuous places throughout the building, and gas lights and candles are available in the operating room in case the supply of electricity fails. The company has various additional precautions under consideration, such as the provision of rubber hose fire insulating barriers in the main switchboard between the main cord shelf and the multiples, asbestos or woolen blankets for the operating room, additional extinguishers, fire shutters, etc. It has also been suggested to fill two pairs of bellows with fire extinguishing powder and hang them on the wall behind the switchboard, on the ground that the powder could be much more readily directed in case of fire than when it is thrown from a tube.

The Boulder office is handling something like 10,000 calls per day at present. At the time of writing there were 1031 subscribers connected to the Boulder office, 405 of the stations being business and 626 residence 'phones. The population of Boulder is about 10,000, including the towns of Longmont and Lyons, to which free two-way trunking is allowed; there are 1723 stations connected to the exchange. One-way free trunking is allowed to Niwot, Marshall, Erie, Superior, Louisville and Lafayette. The toll rate to Denver is 25 cents day or night, on the three-minute basis, and the traffic is handled by four circuits, three being No. 10 B. & S. copper wire and the other No. 12. The distance is about thirty miles, and the toll service is so quick between Boulder and Denver that it has earned the name of the "rapid fire" circuit. A call has been put through in 15 seconds, and it is usually unnecessary for a subscriber to hang up his telephone in calling any Denver number. This speed is accomplished by carrying the toll lines from Boulder direct to the main subscribers' switchboard at the Denver main office, located on Champa Street, so that a call from Boulder is handled by the Denver local operator almost as quickly as a call originating in Denver itself. Between Boulder and Lafayette is a toll circuit of No. 12 copper and also a No. 12 iron trunk line. Another trunk line is to go in at once between Boulder and Erie, and two No. 14 iron trunks between Boulder and Broomfield, in addition to the two No. 12 iron trunks now in operation. The main toll line between Denver and Cheyenne, Wyo., a circuit of No. 8 B. W. G. copper wire, connecting the Colorado Telephone Company's lines with those of the Rocky Mountain Bell Telephone Company on the way to Salt Lake City, passes through this district. An interesting circuit tributary to Boulder runs to Ward (26 miles by rail), in the heart of the Rockies at an altitude of about 9400 feet. This is of No. 12 B. & S. copper, continuing No. 14 iron from Ward to Eldora. A No. 12 B. & S. copper circuit runs from Boulder to Germantown, with a branch at Sunshine, Gold Hill and Watt Street, and thence to Sugar Loaf by No. 14 iron wire. All this region is noted for mining and for mountain scenery, while to the north and east of Boulder are many fine ranches supplied with telephone service. There are no private branch exchanges or drug store pay stations in Boulder. The system was cut over from magneto to common-battery service in the new office on January 3 of this year. Eight party-line circuits are in use for miximum distribution. The wires in the business district are now largely underground.

The rates at present in force in Boulder are eight-party business telephone, $30 per year; two-party line, per instrument, $48; one-party line, $60; residence telephone, eight-party line, $18; two-party line, $30; one-party line, $42.

Colorado has more toll lines per capita than any other state outside of New York. The lines of the company radiate from Denver, Colorado Springs and Pueblo, giving service to all the important towns and mining camps in the state, as well as to Montana, Wyoming, New Mexico and Utah. Every type of line construction is encountered, from lines crossing the Continental Divide in submarine cables at an elevation of nearly 14,000 feet to city to ranch lines involving problems far different from those solved in the mountains. Within the past year or so common-battery offices have been established in Pueblo, Salida and Trinidad, besides Boulder and Denver, while Colorado Springs was one of the first places in the West to be equipped with the central-energy system. Fort Collins and Grand Junction will probably be cut over to the common-battery system by the time this article is printed. Although the Colorado Telephone Company's system crosses the southern boundary of the state at two points and almost crosses the eastern and western boundaries, it has but one connection with other systems, that being at Cheyenne as stated before.

The writer's thanks are due to the following officials for courtesies and data: E. B. Field, president; H. A. Rhodes, chief engineer; G. E. McCarn, assistant engineer; W. L. Cozad, traffic manager, and W. E. Kitterman, agent of the company, in charge at Boulder.

THE ELECTRIC POWER FIELD.

BY GEORGE E. WALSH.

The transmission of electricity over great distances at less cost and waste than ever before is rapidly increasing its sale to power plants in cities. Small consumers naturally look to the large electric power companies for their current, but the tendency of large consumers to purchase power "in bulk" is also very apparent. The average factory, mill or other plant not equipped for generating electric power finds as a rule that it is more economical to purchase the current from some outside company. Large manufacturing plants are the best purchasers of electric power, and the number of these who depend upon outside electric power increases each year. The large sellers of electric power established at Niagara, Massena and Sault Ste. Marie first encouraged this new field, and they are to-day supplying scores of factories and mills with low-rate power sold according to the amount used. By charging a very small price for power used in large quantities, the companies have stimulated the growth of whole groups of factories along the line of their transmission.

But in other parts of the country the effort to produce electricity for supplying factories and mills has only in recent years met with any encouragement. In New England, where the boot and shoe factories are very numerous, the purchase of electric power for operating their machines is still small, probably not more than 500 horsepower being thus used. The same is true of the woolen and cotton factories of New England. Most of the few that have adopted electricity for their motive power have established their own generating plants. One woolen factory, however, near Springfield, Mass., has found that it pays better to purchase electric power from outside sources than to establish a plant of its own.

In a recent investigation of the subject it was found that some thirty odd sellers of electricity for power purposes supplied over 330 metal-working shops with current on a large scale, 175 wood-working factories, 48 cotton factories, 375 printing establishments, and 27 boot and shoe factories. None of these plants used more than 500 horsepower, and the cost of operation varied greatly; but in nearly all instances the companies reported a reduction in expenses by the substitution of electricity when purchased outside.

The construction of large steam-driven stations for supplying electricity in large towns and cities has tended toward the introduction of new industrial factors that promise revolutionizing results almost as great as those produced by the harnessing of Niagara. The fuel problem is becoming more difficult of solution every year in many localities. Factories and mills have had to move away from towns and cities where they were suitably located as to markets and supply of raw material, owing to the high cost of coal and inconvenient delivery. Moreover, the great amount of coal storage room required in a city, where land is costly, makes steam-operated plants expensive, and many are to-day considering the question of moving or purchasing electric current. Steam-driven electric stations located just without city limits offset these unfavorable conditions, and in many instances they offer ideal results. Certain kinds of manufacturing plants prefer town sites, and they must consider the cost of land carefully.

It is for this reason that so many printing establishments have utilized electricity for operating presses and other machinery. The printing plants must of necessity be near the commercial centers, and the trouble and expense of supplying them with coal tax their resources severely. With electricity transmitted from some central station at wholesale rates the cost of operating has been found to be less than by steam. The saving in space and cleanliness is even more conspicuous.

Metal-working shops likewise find electricity of commercial value to them. In this case it is not so much that the plants must be located in the large business centers, but owing to the great number of small machines to be operated electricity is the only power that can give the highest results. With individual motor drive the workmen have better control of their tools and the best results are obtained at less outlay.

The ability to make low rates for manufacturing purposes is easily solved along large water courses, but the plants wishing to purchase electricity are not always conveniently located for utilizing it. Long-distance transmission is thus one of the important factors in this class of work. The Western power companies have apparently solved this question satisfactorily. The Washington (Spokane) Water Power Company sends current over a distance of 110 miles for commercial purposes, selling power to dozens of plants and manufacturing companies along the line of transmission. This long-distance plant supplies mines chiefly with power at rates far less than could be made by any independent company operating in the mines, or by any plant run by the different companies for their individual use. Both at the Standard and Hecla mines there are operated four General Electric 300-h.p. induction motors to drive compressors and hoists. At the present writing all the power generated by the plant is sold to individual mines, and satisfaction is obtained on both sides.

Another electric power plant is selling power at a distance of 140 miles from its generating station. This plant is located at Colgate, Cal., and its line of transmission is from the high mountainous regions to the shores of San Francisco Bay, 140 miles distant. Throughout its whole length there are mills, factories, mines, smelters and lighting and railway plants purchasing the current. Numerous other water power plants send their power great distances with financial success both to themselves and the purchasers. The one at Shawinigan Falls, Montreal, has a transmission line 83 miles long and the one at Canon Ferry, on the Missouri River, finds customers 65 miles distant.

The question of supplying mills and factories with electric power at low rates when they are located outside of what may be called the water power zone offers difficulties the solution of which is greater than those presented elsewhere. There is a limit to long-distance transmission, for there is nothing more certain than that a point must eventually be reached when the current cannot be transmitted any farther without too great a cost. The sale of power on a large scale and at little cost is really more important to the commercial world beyond the region of water power than within that zone.

Steam-driven stations for supplying electric power on a large scale are already working satisfactorily in some parts of the country. At Montreal, for instance, a steam-driven station used for lighting purposes recently entered the power field, and is now selling to a cotton factory power to operate motors aggregating over 3,400 horse-power. This factory has, since its change of power, reduced the cost of operation and found the purchase of power from an outside generating company eminently satisfactory.

Steam-driven stations can never compete with water power stations in long-distance transmission, nor is it necessary, but it is quite evident that companies can work the field of generating electric power for customers in manufacturing centers without fear of loss, and with a certainty of profit. Heretofore the plants selling electricity in such regions have been railway systems or electric lighting plants, which found that they had some surplus energy that they could dispose of profitably. Such plants cannot operate in all parts of the country. In many of the New England States their charters forbid them to sell power. There is a prejudice against increasing their rights in this respect, and manifestly the only solution of the problem is for companies to enter the field to manufacture power for general distribution, as the water power companies have done around Niagara and Massena, and on the Pacific coast.

THE REPULSION MOTOR.

BY A. S. M'ALLISTER.

Much has appeared recently in technical literature concerning the performance of the repulsion motor, and almost every writer on the subject has brought forward a different mathematical theory of the properties. The present writer has no intention of attempting to produce an additional theory or to add to the information on the subject. It is believed, however, that there is yet room for a treatment which will allow of the investigation of the inherent characteristics of the repulsion motor in a manner so simple as to be readily comprehended, and one which is devoid of the usual array of mathematical symbols which are of use only to him who wishes to design such a machine.

The repulsion motor is a transformer, the secondary core of which is movable with respect to the primary, and the secondary coil of which remains at all times short-circuited in a line inclined at a certain angle with the primary coil. Such a machine is represented diagrammatically in Fig. 1. Superficially considered, current which flows in the secondary (the armature) by way of the brushes acts upon the field produced by the primary current to give the armature a torque which retains its direction with the simultaneous reversal of the two currents. If the brushes were placed in line with the field poles, maximum current would be produced in the secondary, but it would have no tendency to move because such torques as are produced on one side of the armature would be opposed by those produced on the other. Similarly, if the brushes were placed at right angles to the field axis no torque would be obtained, for no current would flow in the secondary. A further analysis will show that the torque depends directly upon the product of the secondary (armature) current and that part of the field magnetism which is in mechanical quadrature with the radial line joining the secondary brushes and which is in time-phase with the armature current. In fact, the torque follows a law similar in all respects to that which holds for direct-current machines.

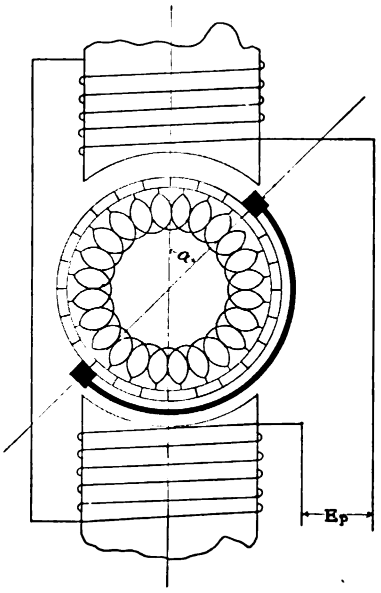

FIG. 1.—CIRCUITS OF REPULSION MOTOR.

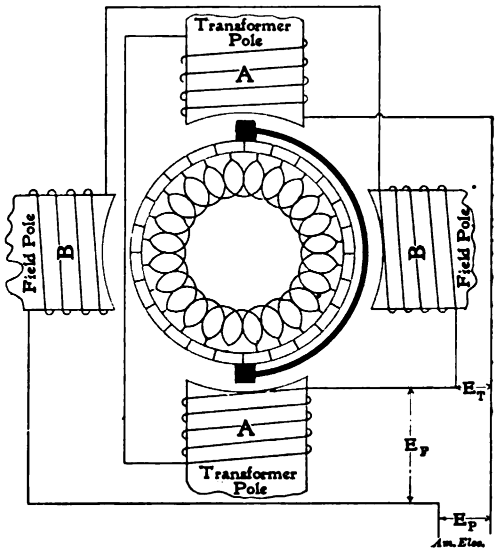

FIG. 2.—CIRCUITS OF IDEAL REPULSION MOTOR.

For the purpose of analysis, it is convenient to divide the primary magnetism into two components, one in mechanical quadrature with the line of the brushes, to give the torque, and one directly in line with the brushes, which produces current in the secondary by transformer action. In commercial repulsion motors the primary winding is distributed over an approximately uniformly slotted core without the projecting poles shown in Fig. 1, and the assumption is made that any given angle, α, to which the brushes are shifted from the field line, the flux component in line with the brushes is $\Phi \cos \alpha$, and that in quadrature is $\Phi \sin \alpha$, where Φ is the total primary flux. This assumption is more or less justified by the fact that when no current flows in the secondary, such component values of fluxes give a resultant equal to the primary flux and having the proper mechanical position on the core. As will appear later, however, this assumption leads to error in assigning values to the two flux components. In order to eliminate all trouble from this source and to allow the conditions to be clearly presented, it is well to divide the primary winding up into two parts placed upon two projecting cores in mechanical quadrature one with the other, and to locate the brushes in line with one core, as shown in Fig. 2. As the simplest possible case, it will be assumed that the number of turns on one core is the same as on the other and equal to the effective turns on the armature. Under the conditions assumed, when no current flows in the secondary the primary field would have a resultant located 45° from the line joining the two brushes.

If the secondary brushes be connected together while the rotor is stationary, the transformer action of the flux in *A* will cause a current to flow in the secondary, which current tends to reduce the flux in *A* and allow more current to flow in the primary coil and to increase the flux in *B*. If the transformer action were perfect, no flux would remain in *A*, while the flux in *B* would assume double value and the current in the secondary would equal that in the primary (the primary and secondary turns at *A* being equal). Such a condition would exist if the primary and secondary coils were devoid of resistance and local reactance (magnetic leakage).

Primary resistance and local reactance at *A* being negligible, when the rotor is stationary the e.m.f. across the coil on the core *A* will be zero, while that on *B* will be equal to the total impressed e.m.f. Assume that the core material at *B* and through the armature is such that the flux produced is in time phase with the current in the coil and proportional at all times to such current; that is to say, that the reluctance of the magnetic path of *B* is constant. Let it be further assumed that the reluctance of the magnetic circuit of *A* is equal to that of *B*. It should be noted that these assumptions are equivalent in all respects to those which are invariably implied in a mathematical or graphical treatment where the coefficient of self-induction, *L*, is taken as constant.

The production of torque at the rotor can now be investigated. The flux in *B* is in time phase with the primary current, while the current in the armature is in phase opposition to that in the coil on *A*. Therefore, the armature current is in time phase with the field magnetism, and the torque (the product of the two) retains its sign as the two reverse together. If the armature be allowed to move, a certain e.m.f. will be generated at the brushes due to the fact that the armature conductors cut the field magnetism of *B*. This generated e.m.f. will at each instant be proportional to the product of the field magnetism and the speed, and will, therefore, be in time phase with the magnetism of *B*. Since the resistance and local reactance of the armature circuit are negligible, any unbalanced e.m.f. at the brushes would cause an enormous current to flow through the armature. Such current, however, would produce a flux in time phase with itself and the rate of change of the flux would generate an e.m.f. opposing the effective e.m.f. which causes current to flow, the final result being that there flows just that amount of current, the magnetomotive force of which produces a value of flux the rate of change of which through the armature generates an e.m.f. equal and opposite to that due to the speed. Now, the flux thus produced alternates through the winding on *A* and generates therein an e.m.f. equal to that similarly generated at the brushes and in time phase with the brush e.m.f. Since the flux at *B* is in time phase with the e.m.f. across the winding on *B*, and the e.m.f. counter-generated in the winding on *A* is in time phase with the flux in *B*, the e.m.f. across the winding *B* is in time quadrature to that across the *A* winding. The vector sum of the e.m.f.'s at *A* and at *B* must be equal to the constant line e.m.f., *E*.

The facts just stated lead to the very simple graphical representation of the phenomena of an ideal repulsion motor shown in Fig. 3, where *A C* represents in value and phase the impressed e.m.f., *E;* the line *A B* equals the e.m.f. across the winding, *A*, at a certain armature speed, while *B C* is the corresponding e.m.f. across *B* at the same speed. It will be noted that since at any speed the e.m.f's *A B* and *B C* must be at right angles and have a vector sum equal to *E*, the locus of the point *B* is a true circle and can at once be drawn when *A C* is located. Since the e.m.f. of the *A* winding is proportional to the value and rate of change of the flux in the core *A*, and such flux is proportional to the current in the coil, the current in the winding, *A*, is proportional to the e.m.f., *A B* (Fig. 3) and in time quadrature to it, as shown at *A D*. A little consideration will show that the locus of *D* is a true circle having a diameter *A F* equal to the primary current at standstill.

It has been stated that at starting the primary and secondary currents were equal in value, but that under speed conditions another current was produced in the secondary. The value of this additional component of the secondary current, which must be such as to give the magnetism in *A* (Fig. 2), may be found as follows: The magnetism in *A* is proportional to the e.m.f. across the winding of those poles. Hence, the current to produce such magnetism must be proportional to the e.m.f. and in time quadrature to it; or, if in Fig. 3 *B C* is the e.m.f. just referred to, *C G* is the component of secondary current to produce the corresponding flux. The locus of *G* is a true circle with a diameter equal to *A F* of the primary current, as will be apparent from what has been stated previously. The vector sum of the components, *C G*, of the secondary current and *C H*, equal and opposite to the primary current, gives the true secondary current both in value and phase position.

It is evident that at a certain speed the e.m.f's represented by the lines *A B* and *B C* in Fig. 3 will be equal in value. It is interesting to note what occurs at this speed. Since the e.m.f's generated are equal and in time quadrature, the magnetic fluxes must similarly have equal values and be in time quadrature. It will be recalled that the magnetic condition at this speed is similar in all respects to that found in two-phase induction motors; that is, there is produced a true uniform rotating field (if a continuous core be used) moving at "synchronous speed." At other armature speeds there is produced similarly a revolving field traveling at synchronous speed, but the field varies in intensity from instant to instant, giving what is termed an "elliptically revolving" field, one axis of the ellipse remaining in line with the brushes and having a value proportional to, but in time quadrature with, the e.m.f. of the winding of *B*, Fig. 2, or length *A B* in Fig. 3, the other axis being in line with the field poles, *A*, and proportional to the e.m.f. across the winding on them, *B C*, in Fig. 3. It is noteworthy that such an elliptical field is also characteristic of the magnetic condition found with single-phase motors. It should be carefully noted, however, that the term "synchronous speed" refers to the change in position on the core of the maximum magnetic flux existing at each instant and has no direct bearing upon the maximum speed which the rotor may attain, which maximum speed, in fact, is limited by conditions other than those here assumed to exist.

By the use of Fig. 3 the complete performance of an ideal repulsion motor may be determined if values be assigned to the scales chosen for the current and e.m.f. Table I records such calculations of the performance of a certain repulsion motor, of which the field reactance is 10 ohms when operated at a constant impressed e.m.f. of 100 volts; that is, in Fig. 3, $A C = 100 \ V.$, $A F = 10 \ A$. The method of making computations is indicated at the head of each column of the table. It will be observed that there have been chosen certain values of the e.m.f's across the field coils on the poles *B* (Fig. 2) and the corresponding values of the e.m.f's across the transformer coils on the poles *A* have been calculated.

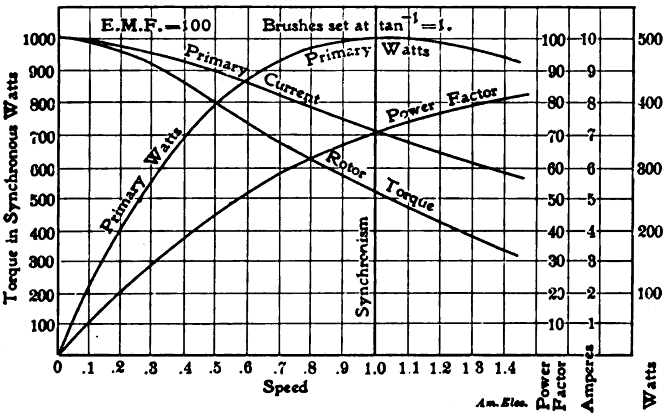

FIG. 4.—CHARACTERISTICS OF IDEAL REPULSION MOTOR.

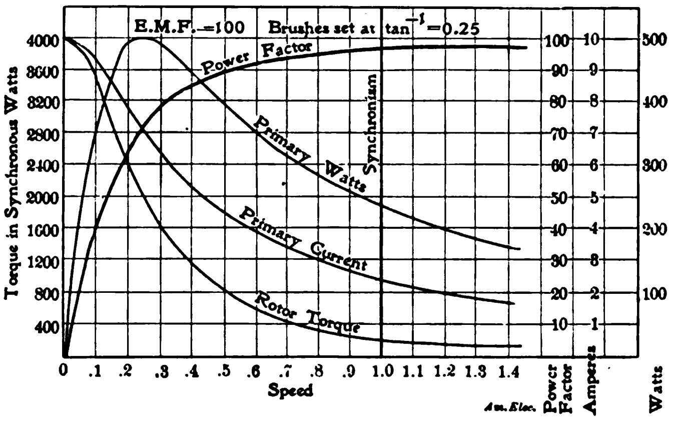

FIG. 5.—CHARACTERISTICS OF IDEAL REPULSION MOTOR.

As will be seen, the work of determination has been much simplified by assuming e.m.f. values corresponding to the product of the impressed e.m.f. and the sine and cosine values of angles at five-degree intervals, so that almost all values recorded in Table I have been taken directly from trigonometric tables.

The speed is found as follows: With an equal number of turns in the windings on *A* and *B* of Fig. 2, when the e.m.f's across these windings are equal, the speed is synchronous, and this speed is given the value 1. Now, at other speeds, the e.m.f. across the *A* winding will be proportional to the product of the speed and the flux in *B*; that is, the e.m.f. in the winding, *B*, as shown previously. It will be apparent, therefore, that the speed is the ratio of the e.m.f. across the coils on *A* to that across the coils on *B* of Fig. 2, or to the ratio of the lengths *B C* to *A B* in Fig. 3. It will be noted that this ratio is the cotangent of the angle *A C B* arbitrarily chosen at five-degree intervals, so that the speed may be taken at once from trigonometric tables. The torque is expressed in synchronous watts, as the ratio of output to speed.

Columns 6 to 11 of Table I have been calculated on the assumption that the brush angle a of Fig. 1 was 45°, or what is the same, that the number of turns on field poles *B* was equal to that on the transformer poles, *A*, Fig. 2, and these calculations are graphically represented in Fig. 4. In Fig. 5 are given the characteristics of an ideal repulsion motor with the brush angle a of Fig. 1 having a value such that its tangent is 0.25, and the calculations recorded in columns 6′ to 11′ are based on this assumption. The conditions here assumed are equivalent to what would be obtained if the number of turns on the field poles, *B*, were 0.25 of the turns on the transformer poles, *A*, Fig. 2. It is further assumed that the coils on poles B are the same in number as previously; that is, that the field reactance is 10 ohms as before, and that the turns on both the armature and transformer poles have been increased to four times their first value.

The method of calculation is quite the same as before, but perhaps a word is needed as to the calculation of the speed and secondary current. At synchronous speed, the magnetism in the field poles, *B*, is equal to that in the transformer poles, *A*, as noted above. Due to the increased number of turns on the transformer poles, at synchronous speed, the e.m.f. across the coils on *A* will be four times that across the coils on *B*, Fig. 2. A consideration of this fact leads to the conclusion that the speed is all times equal to one-fourth of the ratio of *B C* to *A B* in Fig. 3; that is, the speed is equal to one-fourth of the cotangent of the angle Θ, arbitrarily assumed, and hence may quite readily be computed.

The component of secondary current to counterbalance the primary current is equal and opposite to the primary current, since the armature turns are equal in number to the transformer turns on *A*; but the current to produce the magnetism in the transformer poles under speed conditions will at all times be one-fourth the value required to produce the same magnetism in the field poles, as will be seen from column 10′ of the table.

A comparison of the curves of Fig. 4 with those of Fig. 5 will reveal the effect of shifting the brushes from the 45° position farther toward the axial line of the transformer poles. It is essential for good performance that the angle of brush shift from the transformer position be quite small, usually from 12 to 16°, depending upon the constructive constants of the machine.

It must be very carefully noted that the curves here given are for an ideal repulsion motor, all resistance, local inductance and short-circuiting effects having been neglected, and that such curves cannot be realized in practice. It is worthy of note, however, that upon the characteristics here shown are based the discussions of the properties of the repulsion motor which have occupied so much space in the technical papers.

◆

FEEDING STEAM BOILERS.

BY R. T. STROHM.

Feed water may be supplied to a boiler in any one of three ways. The simplest method is to use the force of gravity, in which case the source of supply must be above the level of the water in the boiler. Another method is to use an injector, or inspirator, as it is sometimes called. The third method is to use a pump. The requisites of a good feed apparatus are that it shall supply a sufficient quantity of water, as required, and that it shall not fail to operate properly when called upon for service. Capacity and reliability are the main points to be observed in selecting a feeding device.

The simplest gravity feed apparatus is that shown in Fig. 1. It consists of a tank, *A*, supported by saddles attached to the top of the boiler shell. The feed supply pipe, *B*, is fitted with a globe valve, *C*, while the pipe, *D*, and its valve, *E*, give communication between the tank, *A*, and the boiler. The operation of the device is very simple. First, the valves, *E* and *F*, are closed, and the petcock, *G*, opened. Then, on opening the valve, *C*, water flows into the tank, *A*, forcing the air out at *G*, until the tank is almost filled. The valve, *C*, and the cock, *G*, are then closed, and the valve, *F*, opened. Live steam is thus admitted from the boiler to the water. As the pressure in the tank is the same as that in the boiler, the water flows from the former into the latter by the action of gravity, as soon as the valve, *E*, is opened.

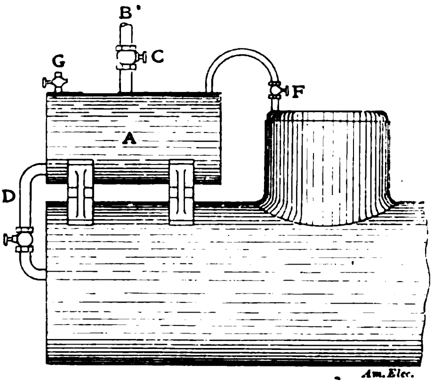

FIG. 1.

While extremely simple in its construction and operation, this form of feed apparatus is out of the question where large quantities of water must be fed. For the valve must be operated by hand, and to accomplish this at proper intervals in large plants would require the undivided attention of one or more attendants. Moreover, the feeding would be spasmodic, and in large quantities at a time, whereas a steady flow of feed water, equal to the rate of evaporation, is desirable from an economical standpoint, as well as from the point of view of the fireman, who aims to maintain a steady working pressure in the boiler. Hence, we find automatic gravity feed apparatus, by which the flow of feed water is fairly constant, the amount being adjusted by hand, to suit the load on the boiler.

One of these automatic systems, illustrated in Fig. 2, makes use of a steam trap through which the water is intermittently discharged into the boiler in small quantities. Fig. 3 shows the construction of the trap. The bowl, *A*, swings on the hollow trunnions, *B* and *C*, and is attached to the counterbalance, *D*. Rigid with the bowl casting is an arm, *E*, which operates the steam valve, *F*. The operation of the system may be understood by reference to both Figs. 2 and 3, in which the same parts are designated by the same letters. The water of condensation enters the bowl, *A*, through the pipe, *J*, and the hollow trunnion, *B*. As soon as the weight of the bowl and the water becomes great enough, it overbalances the weight, *D*, and the bowl sinks downward until it rests upon the frame, *G*. This motion of the bowl causes the arm, *E*, to rise and engage the nuts on the valve stem, opening the valve, *F*. Steam is thus admitted from the boiler through the valve, *F*, into the hollow trunnion, *C*, whence it flows into the upper part of the bowl, *A*, through the curved pipe. This subjects the water in the trap bowl to the same pressure as that carried in the boiler, and as the trap is above the boiler, the water flows out through the trunnion, *B*, into the pipe, *M*, and thence into the boiler. When the water has been discharged the weight, *D*, draws the bowl upward again, closing the valve, *F*, and at the same time opening the small valve beneath *F*. This allows the steam remaining in the trap to be exhausted into the ashpit, reducing the pressure inside the bowl to that of the atmosphere. The water then fills the trap again, and the operation is repeated. The check valves on either side of the inlet, *B*, are simply to prevent egress of water from the boiler while the trap is filling and to prevent the water from flowing back through the pipe, *J*, when the trap is discharging.

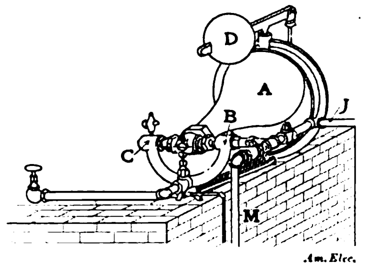

FIG. 2.

It will be seen that this arrangement can be used only when the source of supply is above the level of the steam trap. This is not always an obtainable condition, however, and when it is not practicable, a duplex system may be employed. In this system two traps are used. One of them is placed at a level where the water supply will readily flow into it, and is piped so as to discharge into the second, which is placed above the boiler as in Fig. 2. The lifting of the water is accomplished by the energy in the steam from the boiler. The rate of feeding is regulated by means of a globe valve on the pipe, *M*, which throttles the supply and hence determines the rate of influx.

The injector is an instrument by which the energy of a jet of steam is imparted to a column of water so as to force the latter into the boiler. The injector has always been an object of curiosity to many who fail to understand how a jet of steam at a given pressure taken from a boiler is able to return again to the boiler taking along with it a column of water. The action becomes even more mysterious when steam of a low pressure is used in an injector to force water into a boiler carrying a considerably higher pressure. There is nothing inexplicable or mysterious, however, in the action of the ordinary injector. Fig. 4 shows a vertical cross-section of a well-known make, a description of whose action will serve to make clear the principles upon which all injectors operate.

The inlet, *A*, is for the attachment of the steam pipe leading from the boiler, this pipe being provided with a stop valve, not shown. The water supply pipe is connected at *B* and is likewise furnished with a globe valve. The outlet, *C*, leads to the water space of the boiler, the feed pipe being supplied with a stop valve and a check valve. When about to start the injector, the stop valves in the pipes *B* and *C* are opened, the steam valve in *A* and the check valve in the pipe, *C*, remaining closed. All the chambers and the pipes of the injectors are filled with air at atmospheric pressure. The steam valve in the pipe, *A*, is now opened and the steam, passing through the tube, *F*, leaps the gap and flows into the nozzle, *G*, and thence through the tube, *H*, and out at its lower end, where it backs up in the pipe, *C*, and in the chamber surrounding the lower end of the tube, *H*. For the pressure of this steam is less than the pressure of the steam and water on the boiler side of the check valve, and hence the latter cannot be forced from its seat by this steam current. Consequently, following the line of least resistance, the steam continues to back up in the tube, *H*, finally escaping past the upper end of this tube and flowing through the valve, *E*, into the overflow, *D*, and thence to the atmosphere, since the valve, *E*, is held shut simply by its own weight and the pressure of the atmosphere. This flow of steam from the pipe, *A*, through to the overflow does not last long, however. For as the steam leaps from the tube, *F*, to the tube, *G*, at a high velocity, it draws an increasing amount of air from the chamber surrounding these tubes, and consequently from the pipe, *B*. This drawing along of the air with the

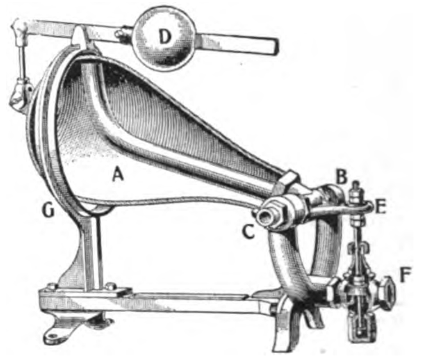

FIG. 3.

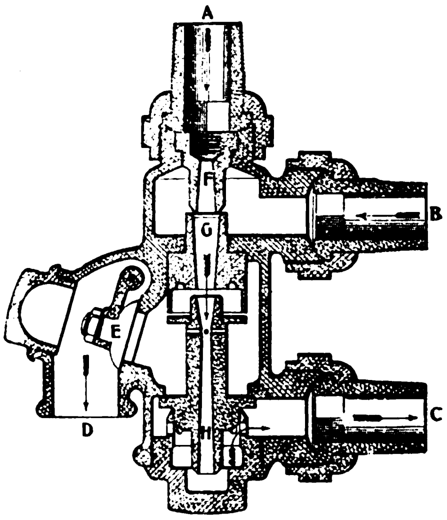

FIG. 4.

steam is due to the fact that a current of any kind, no matter whether it be steam, air, water or any other fluid, has a tendency to induce a movement in the same direction of any medium through which it flows or may come into contact, because of the friction between its particles and such medium. The air being taken out of this chamber, a partial vacuum results, and consequently the pressure of the atmosphere forces water from the supply tank through the pipe, *B*, and into the upper chamber of the injector, until it is filled. Once full, a portion of the water will find its way through the opening between the tubes, *F* and *G*, into the latter, where it will meet and mingle with the steam current. Now, the steam issuing from *F* has a high velocity, and hence possesses a certain definite amount of kinetic energy, or energy of motion. Upon meeting the water in the tube, *G*, it tends to draw the water along with it by reason of the friction set up. This results in largely decreasing the velocity of the steam jet, and at the same time condenses the steam to water, by which process the feed water is heated. The velocity of the jet, while thus considerably reduced, is still sufficiently high to carry the moving column across the space between the tubes *G* and *H*, and thus the current passes from the tube *H* into the pipe, *C*.

As soon as the injector begins to force water from the nozzle, *G*, into the tube, *H*, all escape of steam or water at the overflow, *D*, ceases. At the same time the valve, *E*, closes, due to the pressure of the atmosphere. For, by leaping across the opening between the tubes, *G* and *H*, air is drawn out of the middle chamber in the same manner as out of the upper chamber, and the formation of even a partial vacuum suffices to close the valve, *E*, automatically.

The water continues to be forced into the lower chamber of the injector and the pipe, *C*, until its pressure becomes greater than that inside the boiler. This is by no means impossible. For, on the boiler side of the check valve, there is a column of water under a certain pressure, producing a static pressure on the valve. This water is comparatively still. On the injector side of the check valve there is a column of water moving at a considerable velocity, whose energy is much greater than that opposing it. Hence, the check valve is lifted, and the feed water flows into the boiler, against the pressure of the water contained therein.

The injector thus does work just as certainly as though the steam were allowed to propel the piston of a pump and force the water into the boiler. In either case the energy for the performance of the work is derived from the heat energy of the steam. In the injector this heat energy is changed into kinetic energy by means of free expansion, which takes place in the divergent tube, *F*. The issuing jet is given an extremely high velocity by this expansion, which velocity is afterward transmitted, though much reduced, to the water.

Most injectors are of the class known as lifting injectors, which signifies that they are so constructed as to be able not only to force water into the boiler, but to lift it from a lower level, also. The non-lifting injector does not possess this feature, and consequently it must receive its water supply under pressure from a city main, or from a tank located above the level of the injector. Every injector belongs to either the one or the other of these classes. Aside from the suction of the feed water into the combining chamber, the action of the non-lifting injector does not differ from that of the other class.

Lifting injectors are still further divided into two groups, which are termed automatic and positive. The lifting injector shown in Fig. 4 belongs to the automatic group because, if the flow of water is broken by a sudden concussion, the action will be resumed automatically. They are much used on traction and portable engines for this reason, and doubtless also because of their simplicity of construction as compared with the positive injector. The latter, as commonly found, has two sets of tubes, instead of one. The one set is used to lift the water and deliver it to the second set, the latter then forcing it into the boiler.

Although the injector utilizes about as much steam as would a good pump, it has the advantage of returning all of its exhaust to the boiler without any loss except that due to radiation. Of course, the exhaust from steam pumps may also be utilized in heating the feed water, but not without a larger amount of apparatus, meaning increased cost, space and losses. The injector is a cheap instrument, of little bulk, and of few working parts, which gives the advantage of small and infrequent repair bills.

On the other hand, the injector becomes a most unsatisfactory device if it is not worked under the conditions for which it was designed. In order to operate successfully, the steam pressure must not vary beyond certain limits which are set by the design. The temperature of the feed water entering the injector must not be much more than 100° F., otherwise there will be difficulty in condensing the steam, causing failure to operate, inasmuch as the condensation of the steam is one of the essentials of the action of the injector.

The forms of pumps used for boiler feeding differ somewhat, also. Without doubt the most common is the direct-acting steam pump, in either the single or duplex type. In the former, the valve gear is operated by steam, while in the latter the motion of each piston rod gives motion to the valve for the opposite side of the pump. The direct-acting steam pump is more largely employed for feeding stationary boilers than any other device. In view of the fact that it uses steam full stroke, and is, therefore, not economical as an engine, it must possess certain great advantages which fit it for this purpose.

In the first place, it has no dead centers, and as soon as steam is turned on it starts, provided it is in good condition. It can be made to deliver water at any rate, up to its limit of capacity, by simply throttling the discharge. For the rapidity of movement is proportional to the resistance offered by the water. This makes it easy to adjust the rate of feed water supply to the boiler. Furthermore, the piston has uniform motion throughout its stroke, there being no variation in velocity as in the case of crank-driven plungers.

Fly-wheel pumps make use of the expansive properties of steam, storing up the excess energy in the fly-wheel during the early portion of the stroke, and later giving it up to the plunger. It thus secures an economical use of steam not possessed by the direct-acting pump. However, if it is run very slowly, it may stop on the dead center, from which it cannot start itself. This makes it necessary to control it by throttling the suction, allowing the suction chamber to fill only partly.

The power pump is also used for boiler feeding. It may be attached directly to the shaft of the main engine, or driven by belt, or even operated by a small electric motor. However, if attached to the main engine, either direct or by belt, it can run only when the engine is in operation, which may be disadvantageous at times. Like the fly-wheel pump, it is regulated by the valves on the suction side of the pump.

It will be observed that the method of regulating the direct-acting pump is directly opposed to that used in the case of the power or the fly-wheel pump. The reason must be evident. If the suction of the direct-acting pump were throttled, the water barrel would be but partially filled on the suction stroke. On the discharge stroke, then, the plunger would move some distance against no water resistance whatever, during which time its motion would rapidly accelerate. Upon meeting the water volume filling the remainder of the barrel, the moving parts would be subjected to a heavy shock, which could not but prove detrimental to the pump.

It is very desirable to have at least two independent methods of feeding a boiler, so that, in case either should become inoperative, the other could be used, and thus prevent a complete shutdown of the boiler. Most plants use steam pumps as regular feeders, with injectors as auxiliaries for emergencies.

The point at which the feed water is discharged into the boiler is also a matter of importance. First of all, the incoming current ought not to oppose the natural circulation of the boiler. It should be discharged in or near the coolest portion of the water space, so as not to strike hot plates. It should be diffused, rather than in a single stream. It should also be led through the hot water until it attains about the same temperature as the water already in the boiler before discharging from the feed pipe. This pipe should be easy of access, and ought not to interfere with ingress to the boiler through handholes or manholes.

In view of these requirements, the feed pipe usually enters the front head of a return tubular boiler, near the side, above the upper row of tubes. It is then carried straight back, through the water space, to the rear. Here a short horizontal is attached, by an elbow, carrying the feed to a point directly over the middle rows of tubes. Here another elbow is used, to which is attached a short pipe, extending downward, and perforated throughout the greater portion of its length.

In the case of vertical boilers the feed pipe enters the side of the shell, projecting slightly beyond it, and discharges the feed into the water space just above the level of the lower tube sheet, which forms the crown sheet of the furnace. Water tube boilers usually have the feed water enter the rear of the steam drum, below the water line, where the drum runs longitudinally. In case there are several drums, running parallel to the boiler front, the feed is introduced into the rear upper drum. In one type of water tube boiler there is a mud drum suspended in the hottest portion of the main shell, into which the feed water is led, the idea being to discharge the impurities into the mud drum, from which they are easily removed.

◆◆◆

THE TRAFFIC DESIGN OF CENTRAL OFFICE SWITCHBOARDS.

BY A. DALLAM O'BRIEN.

The design of a switchboard for a telephone central office is naturally divided into two parts: one part relating to the purely electrical features, such as the design of circuits and wiring, and the other having to do with the capacity and type of equipment as dictated by the traffic which it is proposed to handle through the board.

The circuits in use at the present time are practically standard, the only modifications in general use being slight changes in the connecting trunk circuits, which may be made necessary by a difference in ground potential at the several offices in a group. It must not be understood that the statement made above regarding the standard condition of switchboard circuits is intended to apply to all boards, as each manufacturer has his own set of standards and each make of switchboard is a type of its own.

In considering the requirements of a proposed installation from a traffic standpoint, there are a number of important features that must be carefully considered, and a successful design requires most careful study. Where it is proposed to replace an existing switchboard by one of a later type, the problem admits of an easier solution than in the case of installing a board in a hitherto unoccupied territory. In the former case it can be safely assumed that the company has at hand data showing the growth of lines in the territory to be served, the calling rate of these lines, and the distribution of the originating and incoming traffic to the office. From this information a sufficiently accurate prediction of the growth which may be expected in the course of a predetermined period can be made, and knowing the calling rate and traffic distribution the design of a switchboard to satisfy the demands is a comparatively simple matter.

It is the usual practice in switchboard installation to design the equipment so that it may be sufficient to take care of the office growth for a certain period of time, which with most companies is usually about three years. There are a number of reasons why this method is followed. In the first place, in the present stage of telephony, when new ideas and new developments are constantly coming to the front, it is an important question as to just how soon apparatus installed to-day will be out of date; moreover, by equipping a switchboard to last for a longer period of time than three years the telephone company is forced to invest money in equipment which lies idle and pays no return on the investment for a considerable period of time. To provide equipment for a shorter length of time than three years would necessitate frequent additions to the board, and this, as every telephone manager who has had experience will testify, leads to more or less serious impairment of the service and consequent dissatisfaction on the part of the subscribers.

In designing a board to serve a new territory, the engineer must be largely governed by comparisons with similar localities, and the calling rate, classes of service and number of lines to be provided for must be carefully worked out. The first step in a design of this kind is, of course, to thoroughly canvass the territory and obtain as many service contracts as possible. The study of "districting," including the location and number of the central offices necessary to serve a given territory, will not be taken up in this article, as the subject has been very thoroughly covered in recent articles by another author, but it must be understood that a study of this kind is absolutely essential to the successful design of a telephone system. In connection with this study, it is usual to prepare a map of the district showing the location of the central offices and the estimated location and the ultimate number of subscribers' lines which will be served from the group of offices under consideration.

In order to obtain the data upon which to base future switchboard designs, it is the custom of operating companies to make records at stated intervals, showing the condition of the equipment. The peg counts, station and wire report and report of connections constitute the most important of these records. The regular peg count is usually taken at monthly intervals and on a day of the week calculated to give an average record of the incoming and originating traffic, the distribution of both classes and the statement of the number of lines of each class of service that are served by the office and the originating calls per line from each class of lines. This record is taken separately for each of the several offices comprising an exchange district, one record furnishing a check upon the others. The station and wire report is also a monthly record and serves to show the number and class of the connected stations and lines. From successive reports, curves may be plotted showing the growth in the total number of connected lines and also the growth in the lines representing the various classes of service. From a continuation of these curves a fairly reliable estimate of future growth may be obtained and a basis furnished upon which to design future installations. The report of connections is made in conjunction with the peg count, and shows for each office the actual distribution of the incoming and originating traffic, such as the number of calls handled to and from the various points with which connection may be made through the central office considered.

There are three classes of service which must be considered in distributing the lines in a switchboard, these classes representing forms of contracts that are entered into between the telephone company and the subscriber. The flat rate contract allows the subscriber an unlimited number of calls within a specified exchange district; with this class of service it is unnecessary for the operator to make any record of the number of originating calls, except in cases where these calls are for points outside the specified district. The message rate contract provides for a limited number of calls to points within a given exchange district: consequently, it is incumbent upon the operator to keep an accurate record of the number of originating calls from lines of this class. With pay station lines it is always necessary to keep a record of the calls, and in addition, where it is customary to limit a connection to a predetermined time, pay station calls must be timed; thus additional labor is involved on the part of the operator.

The originating calls may be divided into three classes: Local, local trunk and toll calls. The local calls are those which originate for stations connected to the originating exchange. Local trunk calls are those for points within the exchange district and which are reached from the originating exchange by means of local trunks. All other calls are classified under the head of toll business and include all originating calls which are for points outside of the exchange district which are reached either through the medium of a toll board, or in some instances, over direct trunks from the exchange itself.

The connecting trunk lines may also be divided into three classes, comprising circuit, ring-down and common trunks. The circuit trunk as at present employed is terminated in a jack at the sending end and in a cord and plug at the receiving end; in addition, the operator at the sending end is enabled to secure direct connection with the trunk operator at the receiving end by means of a calling circuit. The ring-down trunk is terminated in a jack and drop, or visual signal, at the receiving end and is used for sending calls in one direction only, while the common trunk is equipped with a signal at both ends and is used for sending calls in both directions. The efficiency of the circuit trunk is naturally considerably higher than that of either of the other classes and is therefore generally employed.

There are, however, numerous instances which arise in practice, where the volume of traffic between two offices is not sufficient to warrant the installation of circuit trunks, and it has been customary with some companies to limit the application of the circuit trunk between offices where there is a minimum of fifty calls each way per day, and where the traffic falls below this figure to handle the business by means of a common or ring-down trunk. The number of calls which may be handled by a group of trunks is a direct function of the number of trunks in a group, the efficiency curve being almost a straight line, as shown in Fig. 1. This follows naturally from the fact that where the group of trunks is large the liability of finding all the trunks busy at a given time is small, and each trunk therefore may be worked up to its full capacity.

As an example of the application of the methods used in the design of switchboards, an exchange district consisting of five central offices, one of which is a toll office, will be assumed, and the equipment of one central office of the district be determined. It is assumed that the proper districting study has been made and the office in question found to require an equipment of 1400 lines to last for a period of three years from the date of completion, and, further, that this total be made up of 50 flat lines, 1000 message rate lines and 350 pay station lines. Upon the basis of a calling rate of ten for the flat rate lines and a rate of four for the message rate and pay station lines, the total number of originating calls will equal 5900. Assuming 70 per cent of the calls, or 4130, to be local, and 20 per cent, or 1180, to be local trunk, the remaining 10 per cent, or 590, will be for toll points. The calls which are handled over local trunks will be subdivided into four parts for the remaining four offices of the district, which will be designated *B*, *C*, *D E*, the office under consideration being known as *A*.

If 40 per cent of the trunk calls are for *B* and 20 per cent for each of the remaining three offices, then the sending trunks to *B* will be required to handle 472 calls, and each group of sending trunks to *C*, *D* and *E* will have to handle 236 calls. With these figures at hand, an inspection of Fig. 1 will show the number of trunks required as follows:

SENDING TRUNKS.

Office.	Calls.	Trunks.
B	472	9
C	236	5
D	236	5
E	236	5
	1180	24

The incoming trunked calls from the local offices may be safely figured as being equal to the originating local trunk calls, and the number of incoming trunks required for this traffic will be as shown below:

INCOMING TRUNKS.

Office.	Calls.	Trunks.
B	472	9
C	236	5
D	236	5
E	236	5
	1180	24

Considering the originating and incoming toll calls in the same way, there being 490 calls in each direction, and again consulting the curve, it is evident that there will be required nine sending trunks to the toll board and nine incoming trunks from the toll board.

In the example considered, the traffic between office *A* and each of the other offices in the district is of sufficient magnitude to warrant the use of circuit trunks, and there is consequently no necessity for the installation of either ring-down or common trunks.

From the above calculations, the incoming trunk calls are shown to be 1670, and the total number of incoming trunks required would be 33, the outgoing trunk equipment also necessitating 33 trunks. The number of calls that an operator handling an incoming trunk position can complete in twenty-four hours will vary from 2000 to 3500 calls, depending largely upon the class of trunk equipment employed, such as the use of automatic ringing keys and disconnect signals which greatly facilitate operation. As the total number of calls to be handled over incoming trunks in this instance amounts to 1670, the load is evidently well within the limitations of a single operator, and the equipment of one incoming trunk position is therefore ample to supply the needs of the office.

Before determining upon the equipment of this position, it will be well to determine the number of subscribers' position required to handle the traffic. The number of subscribers' lines that can be apportioned to an operator's position is dependent upon the class of service, the calling rate per line and the number of calls that an operator can handle. Owing to the varying amount of labor required on the part of the operator with calls from different classes of lines, it is necessary to make some assumption based upon experience of the allowable operator's load for the different classes of service. The following loads are representative of usual practice in this regard and are, if anything, somewhat conservative:

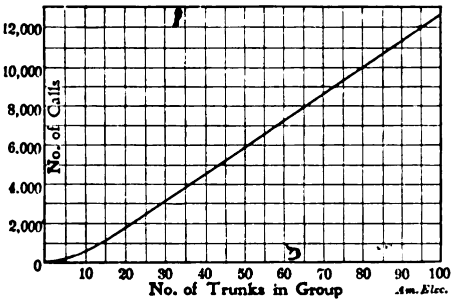

FIG. I.

Class of Line.	Operator's Load.
Flat rate	1600 calls
Message rate	900 calls
Pay station	600 calls

The load of 900 calls, as given above, for message rate service does not consider the use of toll counters, which are automatically operated, either by the subscriber or at the central office, but is based upon the supposition that a check record is made by the operator of each call received. In the example under consideration, the following data have been assumed:

Class of line.	Calling rate.	Number of lines.	Number of calls.	Operators' positions.
Flat rate	10	50	500	.31
Message rate	4	1000	4000	4.44
Pay station	4	350	1400	2.33
Total number of positions				7.08

From this, the number of positions required for the subscribers' operators is found to be 7.08, this result being obtained by dividing the number of originating calls from each class of line by the operator's load for the corresponding class of service. The number of positions having been determined, the distribution of the lines among the different positions must be worked out and the proper number of answering jacks assigned to each position. Dividing the allowable operator's load for a particular class of service by the calling rate per line for that class of service gives the equipment in lines per position, and applying this method to the data previously given, the following results are obtained:

Flat rate lines per position $\frac{1600}{10} = 160$

Message rate lines per position $\frac{900}{4} = 225$

Pay station lines per station $\frac{600}{4} = 150$

The usual subscribers' section consists of three positions and has seven panels, there being 2⅓ panels per position, so that by dividing the above results by 2⅓ the lines per panel are shown to be as follows:

Flat rate	69
Message rate	96
Pay station	68

As the answering jack equipment is usually made up in strips of ten jacks each, the equipment per panel must necessarily be some multiple of ten; thus, equipping the pay station and flat rate panels with 70 lines each, there will be required 400 ÷ 70 = 5 5/7 panels, or say 6 panels. The message rate panels being equipped with 100 answering jacks, each will require 1000 ÷ 100 = 10 panels, making a total of 16 panels. With this data, it is now possible to decide upon the arrangement of the board. In the present instance, by using three-position sections nine positions will be available. The first position will be equipped as an incoming trunk position with 40 trunks, the seven additional trunks being provided to take care of some unforseen demand. The first two panels of the first section will not be equipped with answering jacks, but the remaining five panels of this section and the first panel of the second section will be provided with 70 answering jacks per panel for handling the flat rate and pay station lines; the remaining 13 panels of the second and third sections will be equipped with 100 answering jacks each, it being better to equip the last three panels at the time of installation in order to have a certain amount of capacity above the calculated requirements rather than to run the risk of having to install additional equipment in case the growth of the board should exceed the limits anticipated. Forty outgoing trunks should be multipled throughout the board and each position equipped with a strip of ten calling circuit buttons. As it is a comparatively simple matter to add to the subscribers' multiples, it is only necessary to multiple 1400 lines throughout the board.

The design of the switchboard to last for the period of three years from the date of installation being determined, it is necessary to decide upon the ultimate capacity of the office, or the ultimate number of lines which will be handled through the board.

These results will follow from the districting study previously mentioned. Knowing the ultimate capacity, the ultimate number of switchboard sections can be figured and the space to be occupied by the board determined. From this data, the floor space necessary in the operating room can be decided upon and the location of the present installation so fixed that the board may be capable of additions at either end. As the size of the office increases, the incoming calls will naturally increase, and when more than one trunk operator is required, the first position which was originally equipped as a trunk position may be changed to a subscriber's position by a modification of the keyboard and the addition of answering jacks and two position trunk sections added to the board to take care of the incoming traffic. At the other end of the board, subscribers' sections may be added as necessary.

While only four of the ten circuit buttons installed at the time of opening will be used for trunk calling circuits, several may be required for various instruction circuits, and the remaining buttons will be at hand when the necessity arises for trunks to other points.

In considering the calling rates to be used for the various classes of line in a design of this kind, it is well to use a somewhat higher rate than that shown by experience and by the data obtained. This is due to the fact that as the telephone industry grows, the subscribers become more and more dependent upon the telephone for transacting their business, and as time passes its use becomes more frequent and the calling rate per line rises. The use of party lines may to some extent affect the calling rate, and, consequently, the number of lines which can be handled by an operator; on the other hand, it seems fair to assume that where a party line is used the calling rate per station will be low, and in practice the effect of this class of service does not succeed in raising the calling rate appreciably.

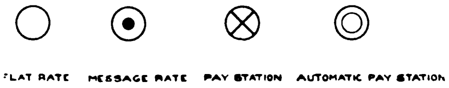

FIG. 2.

Where it is possible to avoid the use of common and ring-down trunks, it is advisable to do so, as the efficiency of these lines falls considerably below that of the circuit trunk, and the labor involved on the part of the trunk operator is also largely increased. It is, of course, necessary that the operator at the switchboard should, upon receiving a call, be able to identify the class of service to which the calling line belongs, and this is usually accomplished by covering the incandescent lamp which serves as a line signal with a small opal cap which is marked with a distinguishing symbol. The symbols which have been used to a large extent by a number of companies are illustrated in Fig. 2, where, it will be noticed, that the flat rate lamp cap is blank. In the case of the board designed herein, it will be noted that one position of a subscribers' section has been equipped with incoming trunks, and that this position being at one end of the section requires the trunk operator to reach across two subscribers' positions in order to have access to the limits of the multiple.

With some types of board this feature may prove objectionable, and in that case it would be well to install in addition to the three subscribers' positions one two-position trunk section and equip the second position of this section with forty trunks. As the two-position trunk sections usually only contain five panels, the multiple being built up higher than in the subscribers' sections, the trunk operator is not forced to reach through so long a distance in order to obtain a connection at the end of the multiple.

There are, of course, a number of special features that always occur in a design of a switchboard for a given case, and these features oftentimes necessitate special treatment. In general, however, the traffic design of a central office switchboard is made along the lines described.

◆

AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

Track Accessories.

It is evident that wherever a switch occurs, or rails are cross-connected, the ordinary methods of connection would short circuit the track. To prevent this, all cross bars are insulated. Such a form of insulator in shown in Fig. 15 at *G*. To insulate the various sections of track, wood splice bars, which are shown at *H* in the figure, are employed.

The adjacent rails at these splice bars are insulated by means of a fiber rail end as shown at *I*. If the limits of a section occur at a curve, the use of wood splice bars is prohibited, owing to the great strain on the rails at such places. For this purpose special fish plates, insulated by fiber bushings are employed.

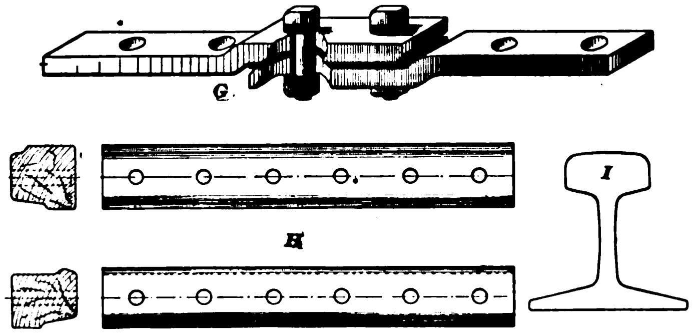

FIG. 15.

The various forms of battery and accessories employed in creating the necessary difference of potential between the rails of a section are shown in Fig. 16. *A* is a Nungesser cell, employing an exciting liquid of saturated caustic soda, with zinc and iron elements, the latter being in the form of a perforated cylinder which is filled with a depolarizer of copper oxide. This cell, on account of its long life, and constancy of operation, with absolute immunity from freezing, is used extensively for railroad crossing signals; but, as yet, has not been introduced to any great extent in automatic signal practice.

The Edison-Lalande cell shown at *B* in this illustration, is of the well-known cast element type, with an electrolyte of strong caustic potash, the elements in this case being of a heavy construction to suit the conditions of long uninterrupted service.

The Gordon cell shown in the illustration at *C* is more largely used than any other for main signal battery purposes; the electrolyte in this cell being caustic soda.

The familiar gravity cell is used almost exclusively for track battery purposes because of its ability to withstand short circuiting for any length of time. The elements which are regarded as the best for signal purposes are shown at *D*, which is the copper, and at *E*, which is the zinc. Both elements when of this form of construction may be cleaned very expeditiously.

The manner of installing track batteries is also shown in this illustration. The iron chute *F*, about 8 feet long, is placed in the ground, from 4 to 5 feet from the track. Connection is made from the rails by wires passing through wooden trunking which are loosely placed in the battery chute and connected to the battery *aa*, which latter are placed in a wooden cage *b*, provided with a rope, by means of which it may be readily removed for cleaning or renewing the battery.

The manner of installing the trunking for connecting the battery wires to the rails is shown in Fig. 17. The trunking *A*, placed about 1 foot under ground, passes to the track connecting wires *E* and *C*, these wires being soldered to insulated copper wires laid in the space within the trunking. A switch instrument is also shown in this illustration, the purpose of which is to short-circuit the track when the switch is open.

The witch point rail rides upon the wedges, *F*, which hold it, therefore, from contact with the rail. The rod, *I*, is not insulated; therefore, when the switch is closed, the track is short-circuited. On account of the uncertainty of this action, the switch instrument *B* also short circuits the track, an end elevation of this instrument and the tie being shown at *G*.

Three forms of battery houses which are in common use are shown in Fig. 18. The battery tank *A*, which is particularly adapted for being installed under ground, is provided with a weatherproof cover, and tiers of shelves, around which the batteries may be arranged, for convenience in inspecting and connecting. The advantage of this type of battery house is that its initial cost is very low, and it eliminates, by its location, all danger of freezing; and excessive evaporation of the liquids in the cells is prevented. The battery house shown in part section and elevation at *B,* and a side view at *C,* is extensively used for locating signal mains. This house is lined with heat insulating materials, shown at *b,* and has its interior provided with rows of shelves *a.* The advantages of this type of battery house are its adaptability to rapid inspection, immunity from being flooded by high water, which is one of the greatest bugbears of railroad signaling, especially during the spring time, or when heavy rains are frequent. Its location above ground also gives free air circulation, and renders it easily portable.

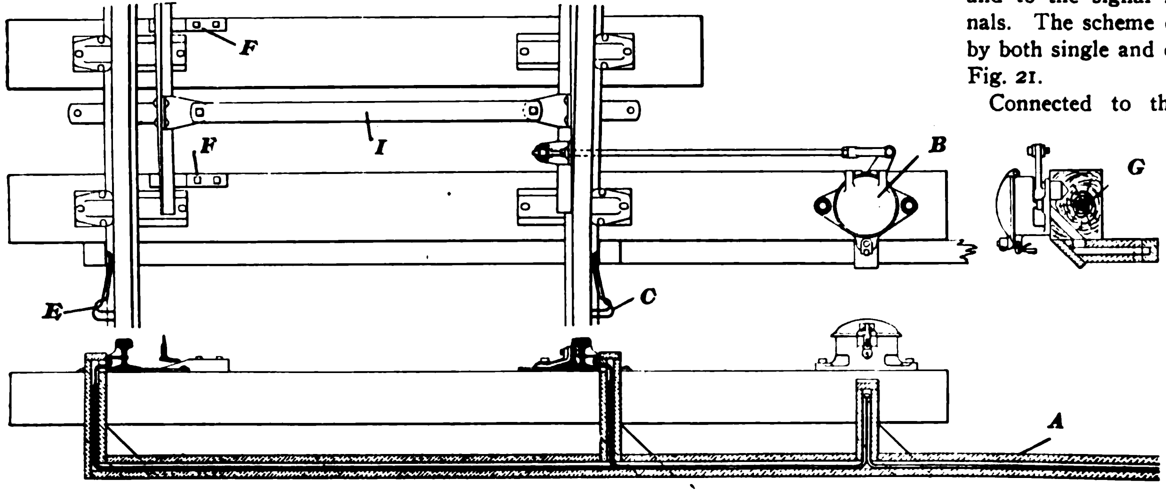

FIG. 17.

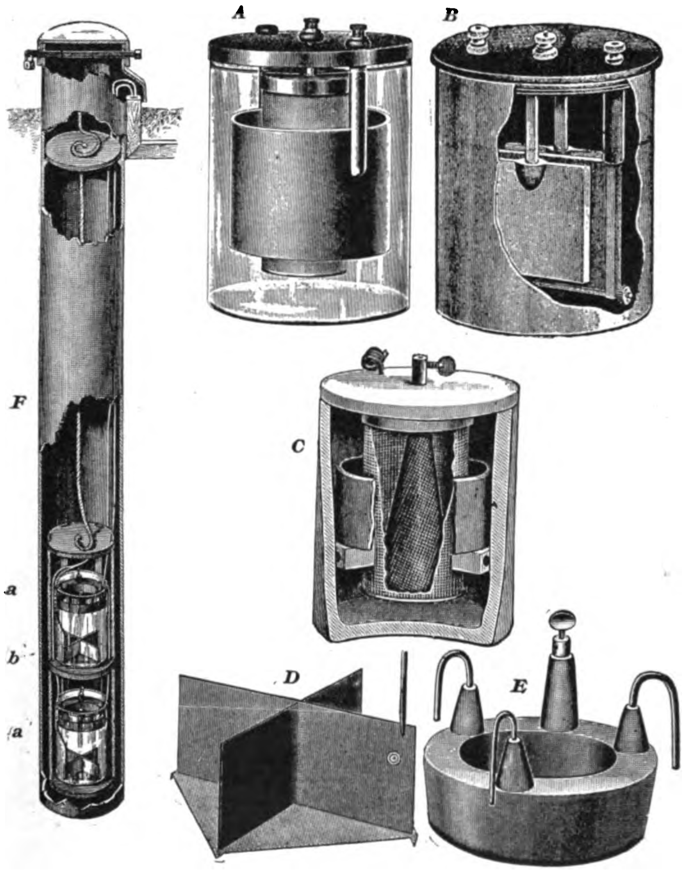

FIG. 16.

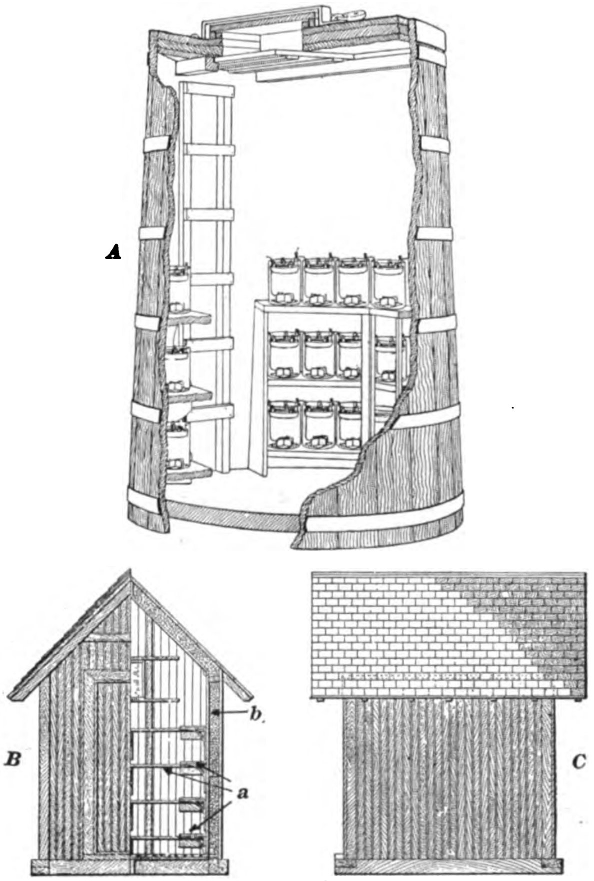

FIG. 18.

Switch Instruments.

The construction of a form of switch instrument which opens the signal circuit is shown in Fig. 19. Upon the wooden base *w,* which is of a width conforming to the number of circuits which are connected to the instruments, is mounted the springy strip *n* in the manner shown.

Riding upon this strip is a small insulated roller *f,* which is carried on the end *m,* of a pivoted lever connected to the point of the switch rail. When the switch is in its proper position the roller forces the end *a* of the spring into contact with the piece *h.* The circuit through the spring is thus closed, one wire being connected to *h* and another to *n.* On opening the switch the action of the roller opens the circuit.

On double track, the switch instrument of a cross-over operates both opposite bound signals. For a home and distant signal, therefore, four sets of contacts are required for each instrument. This is shown diagrammatically in Fig. 20, the wires *a, b, c* and *d* being the home east, home west, distant east and distant west bound circuits, respectively.

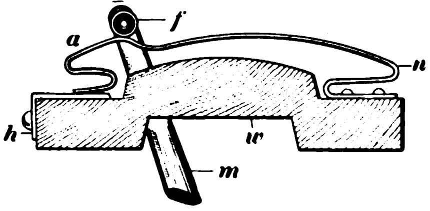

FIG. 19.

With the system employing the method which short circuits the track, it is not necessary to employ line wires passing from and to the signal instrument and the signals. The scheme of connections employed by both single and double track is shown in Fig. 21.

Connected to the single track section shown in the upper part of the figure are the track batteries, *K,* and the relay, *E.* The switch instrument, *B,* which contains two sets (for greater reliability) of contacts, *D,* is connected to the track at the switch, *G.* When the switch is open the track will be short-circuited and thus cause the signal circuit to be opened at the contacts carried on the armature of *E.* To insure certainty of action, the switch point rail, when the switch is in the open position, short-circuits the track.

When the switch is in the normal position, the rail point, by riding on two wedges shown at *L,* and placed on adjacent ties, is kept from contact with the rail, or on any of the wrought iron cross bars or pieces. This renders unnecessary an insulated joint in the switch rail, the cross bond *C* connecting the various rails as shown, insulating joints *N* being placed to render impossible a normal short circuit. If, however, the wheels of a car pass over the siding limiting insulating joints *N*, the signal will be held at danger.

In the lower part of the illustration the connections employed in a double track system at a crossover are shown, the switch instruments *A* and *R* holding, through the action of the armatures on the relays *O* and *S*, the east and westbound signals at danger when the switches are opened.

The arrangement of a switch indicator which will only indicate clear if a train is not within two blocks or sections of it is shown in Fig. 22. This instrument, shown at *i*, receives current from the battery *g*, in series with the two circuit closers *j* and *f*, which are operated by the signals as shown, the other connections of these signals not being given, as they do not effect the operation of this instrument.

The advantages of such an arrangement of connection is that a trainman cannot proceed from a siding to the main line when a train is within two blocks of him. Should *f* fail to open the circuit, it is highly improbable that *j* will not do so. In the lower part of this engraving the arrangement of an indicator *o*, which shows approximately where a train is, is given. The two instruments of this indicator are connected to separate batteries, the circuits of which are controlled by the circuit closers, operated by the movements of the signals *m* and *n* respectively.

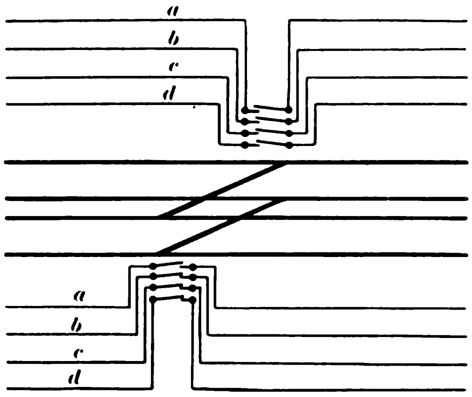

FIG. 20.

The arrangement of a polarized type of switch indicator is shown in Fig. 23. The polarized instrument *c*, placed at the switch *g*, moves according to the polarity of the battery *f*; in series with which is a circuit closer *d*, operated by a relay at this point. The polarity of the current is controlled by the pole changer *h*, operated by a relay at this section. When a train arrives at *d*, the circuit is closed, causing the movable spectacle of *c* to pass before one of the apertures of the instrument. When the train has reached *h*, the polarity of the current passing through *c* is reversed, thus reversing the motion of the spectacle.

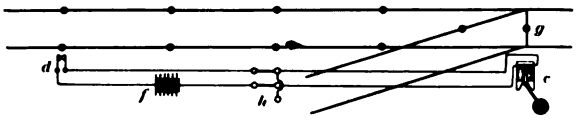

FIG. 23.

A common form of switch instrument is outlined in Fig. 24. This consists essentially of a magnet carrying a movable armature to which a spectacle is attached. This spectacle, moving before the window *h*, provided in the housing placed upon a short wooden plank located at the switch, indicates to a trainman at the switch whether he may proceed from a siding to the main line, or from one main track to another.

Lightning Arresters.

A very important consideration in a signal system, especially if line wires are used, is adequate lightning protection. A common form of arrester used for this purpose is shown in Fig. 25. Upon a porcelain form are mounted the binding posts *A*, *B* and *C*. *A* is connected to the line wire, *C* to the instrument to be protected, and *B* is grounded. The plate *E* is placed a very short distance above the coil of iron wire *D* connected between the binding posts *A* and *C*. When a lightning discharge comes from the line to *A* it will pass around but a few of the turns of *D*, and then jump to the plate *E* across the small intervening air space, and thence to the ground. When a bank of these lightning arresters are connected, the piece *F* on each is used to connect all electrically to the plate *E*, thus rendering necessary but one ground wire. These instruments have proved highly efficient, which is as it should be, since a fused armature contact, brought about by a high potential discharge, is liable to cause a wreck.

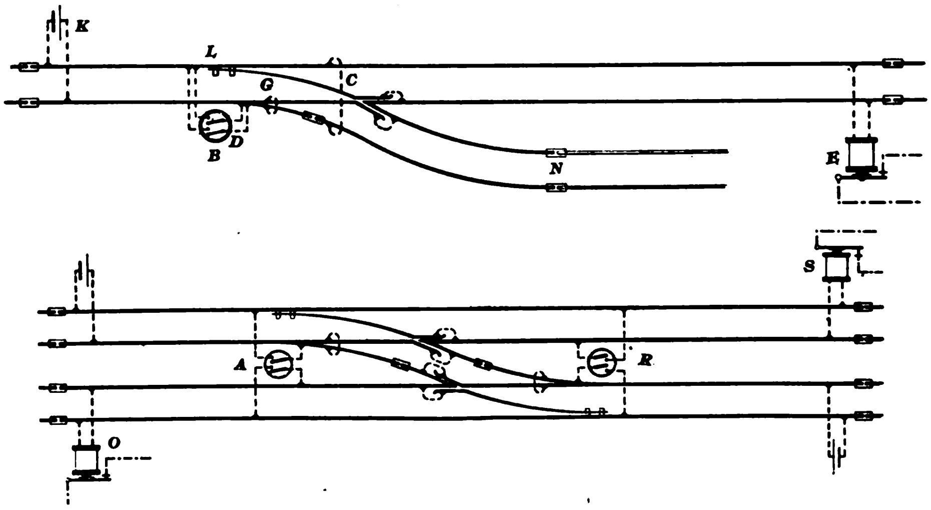

FIG. 21.

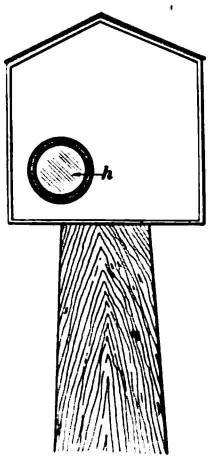

FIG. 24.

Mechanical Signals Automatically Operated

In Fig. 26 is shown a duplex rotary circuit controller and its connections. This circuit controller is secured on the pole of signal *I*, and operated by the rod *M*, which is fastened to the home arm of this signal. This signal is manually operated, and controlled automatically, protecting the track block or section between *J* and *G*. Each signal arm is provided with the electric slots *A* and *C*, which prevent movement of the signal unless everything is in the proper operating condition.

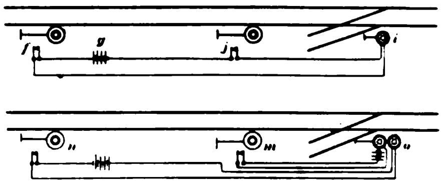

FIG. 22.

These slots are operated by current from the battery *D*, through the contacts of the polarized track relay, *G*. The slot *A* is governed by the neutral armature *F* of the relay *G* and the slot *O* by both polarized and neutral armatures of this relay, and also by the contacts *c* of the circuit controller *E*. The circuit controller, in series with the slot *A*, is operated by the lever controlling the signal arm of *A*. The purpose of this circuit controller is merely to economize in the current consumption, and it is open when the signal arm is in the normal or danger position.

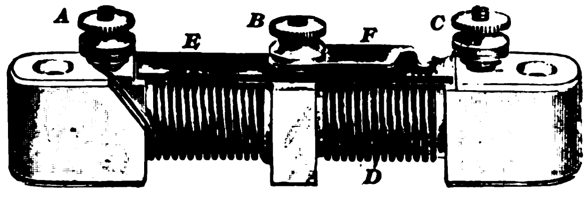

FIG. 25.

When this signal arm is at danger, the contact at *c* is open; therefore the slot *O* is demagnetized, and the arm connected to this slot cannot be cleared until this contact is closed, which action occurs, however, when the home signal arm is moved to the clear position. This distant arm, however, cannot be cleared, if the contacts at *F* and *N* are open, which will be the case if either the track battery *J* is short circuited or has a polarity that holds the polarized contact open.

The pairs of contacts *b* and *a* act in reality as a polarity changer for the track battery *J*, this being effected by the movement of the cam by the rod *M* in a manner which will be evident upon inspection of *E*. The direction of current, therefore, of the rail circuit preceding the signal *I* is reversed with every successive movement of the home signal from clear to danger, or danger to clear. This polarity reversal, by acting upon a polarized relay at the beginning of the track section immediately preceding this signal acts upon the home board and also the distant board of the signal protecting this section.

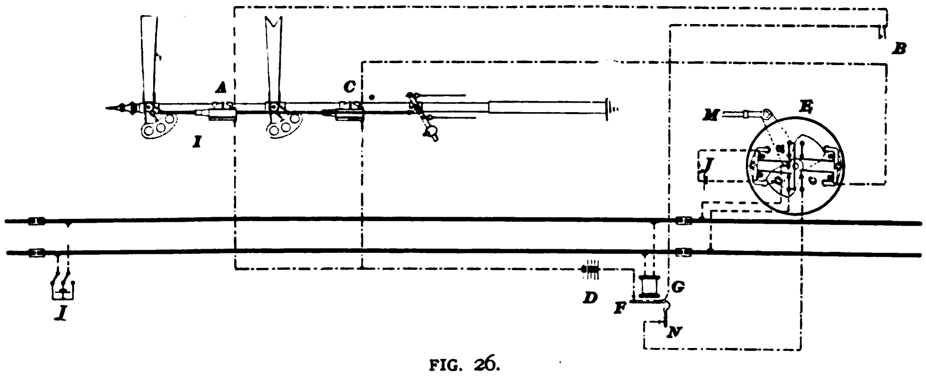

FIG. 26.

The reason for employing cam-shaped pieces in the circuit controller *E* is to prevent any change in the connections until the home signal has entirely completed its stroke, or movement to the full clear position.

Abstracts from Foreign Contemporaries

Single Cylinder Two-Stroke Cycle Gas Engine.—The London *Mechanical Engineer* describes in a recent issue a single-cylinder, two-stroke cycle gas engine devised by B. Brown and F. E. Bowman and illustrated herewith. In this design a scavenging charge is introduced at each revolution to sweep out the spent products of combustion from the explosion chamber, and means are provided for automatically closing the exhaust port as soon as these products are driven out, so as to prevent waste of the mixed air and gas required for the next explosion. The cylinder, *A*, is divided by the piston, *B*, into two chambers, *F* and *G*; the chamber, *F*, being the compression chamber, the charge being drawn into it through a non-return valve, *H*, opening into it by the backward stroke of the piston compressing this charge. Outside this non-return valve a throttle valve and governor are placed by means of which the charge of mixed air and gas is automatically regulated to the requirements of the engine when working under varying loads. Communication between the front, *F*, and the back end, *G*, of the cylinder is provided by means of a passage, *I*, which is opened and closed by the piston itself passing over it when it reciprocates. The piston, *B*, also just before it opens this communication between the front and back part of the cylinder opens on the opposite side of the cylinder a similar port, *J*, through which the spent products of combustion are passed into the atmosphere. This exhaust port, *J*, is so placed that it is fully open before the forward motion of the piston, *B*, opens the port, *I*. The exhaust port, *J*, is not made a continuous opening, but has a grate-like structure, and on the end of the piston, *B*, at the side of which this grating is situated in the cylinder wall at B_1, there is a similar grate or comb, A_1 (see Fig. 2), so that a twist or partial revolution of the piston, *B*, on its axis will cause the comb or grate to close the exhaust port at any time which may be determined before the piston reaches the end of its stroke. To give this axial movement to the piston rod a peg, *K*, is secured to it, which rests in a curved slot formed in a bracket, *L*, secured adjustably to the frame of the engine, so that the reciprocating piston rod, *C*, and piston, *B*, are caused to partially rotate by the peg, *K*, traveling along the curved surface of the slot in the bracket, *L*. On the piston end and opposite to the comb or grate, B_1, which closes the exhaust port, *J*, is a similar projection, *M*, only made solid and not fitting close to the cylinder wall, the object of which is to deflect the incoming mixture of air and gas upward into the far end of the cylinder and thus act more effectually as a scavenging charge. The gas and air may pass from the chamber, *I*, into the cylinder through a grate, as shown in Fig. 2. An electric plug, *N*, is shown at the back of the cylinder for igniting the charge, and water jackets, *O*, are provided surrounding the greater portion of the cylinder. The action of the engine is as follows: On the piston commencing its backward motion the mixture of air and gas is drawn through the induction valve, *H*, into the front of the cylinder, *F*. The forward motion of the piston then compresses this mixture in the front end of the cylinder to a pressure determined by the capacity of the compression chamber. When the piston has moved forward until it opens the exhaust port *J* the spent products of combustion are discharged into the air through the gate *A*, into the exhaust passage *J*, and then the piston still moving forward uncovers the port *I*, communicating with the front end *F* of the cylinder, and the mixed charge under pressure passes into the explosion chamber *G* of the cylinder, and being deflected by the projection *M* on the end of the piston sweeps the contents of the chamber *G* out through the exhaust passage *J*. To regulate or prevent the escape of the mixture of gas and air with the exhaust the gate openings *B*, and *A*, are employed in combination with the peg *K* and curved slot L for imparting an axial movement to the piston, so that before the piston in its backward travel has closed the port *I* it has been moved axially, thereby causing the comb *B*, to close the gate *A*, and exhaust passage *J*, and thus preventing further escape of the compresed gases from the front end *F* of the cylinder. The piston continues its backward motion and further increases the compression in the explosion chamber *G* until the end of the backward stroke is reached, when the compressed charge is fired by the electric ignition plug *N* and the cycle recommences.

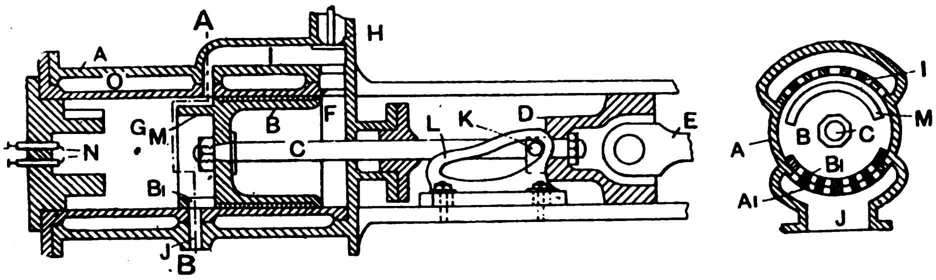

FIG. I.—SINGLE-CYLINDER, TWO-STROKE CYCLE GAS ENGINE.—FIG. 2.

Storage Battery Discharge in Conjunction With a Booster.—While boosters are generally used for charging a storage battery, they are invariably disconnected while the battery discharges and the voltage of the battery is varied by varying the number of cells. This has the disadvantage that the voltage can be regulated only in steps of two volts, and there are always a number of cells which are not fully discharged or not quite as fully as the balance, while there are often cells which are practically never discharged, resulting sometimes in sulphating. *L'Eclairage Electrique* contains an article by M. J. M. G. Doublet, describing the use of a discharging booster during the discharge of the battery, with an improvement in the service of the system. The e.m.f. is regulated by means of the booster, which is kept constantly in service. If the voltage of the battery is too high, the booster acts as a motor, reducing the voltage to the desired amount and driving its motor as a generator. For instance, in order to charge a battery of 300 volts from 220-volt motors, the booster has to give $80 + X$ volts; for this purpose the booster consists of a motor of 220 volts coupled to a generator of $80 + X$ volts. If the battery is discharged through this machine, *i. e.*, if one makes the overvoltage $80 - X$ instead of $80 + X$ volts, the generator becomes a motor and the motor a generator. In varying the excitation either in the generator or in the motor it is possible to vary the discharge current, hence the voltage, as accurately as desired. All cells are then discharged simultaneously to the same degree. During operation of the battery in parallel with a generator, it is possible to regulate the output of each so that the generator always runs with the most favorable load, and as soon as the total load of the station diminishes below this value, the battery is charged again.

Combined Superheater and Steam Generator—The object of the design illustrated by Fig. 3 herewith which forms the subject of a patent recently granted to J. H. Rosenthal, is to provide an independently fired superheater combined in such a way with steam generating elements that the water-circulating and steam-generating water tubes located over the furnace shall, by absorption of part of the fiercest furnace heat, utilize such heat while lowering the temperature of the gases which impinge on the tubes of the superheater, and the water tubes at the ends or sides by presenting a heat-absorbing wall to the action of the fire gases will enable a durable casing to be applied around the superheater without the extensive use of brickwork. Fig. 3 shows a longitudinal section of the superheater. To the right is a front elevation partly in section on line 2—2. Below is a plan partly in section at the line 3—3 and to the right of this is an end elevation of the pressure parts only. The arrangement comprises a skeleton boiler consisting of a steam and water drum, *A*, downcomer tubes, *B*, terminating in cross boxes or manifolds, $C\ C_1$, inclined water-circulating tubes, *D*, connecting cross box, *C*, to a cross box, D_1, into which are expanded tubes, *E*, connected to a cross box, *F*, from which tubes *G* discharge the uprising water and steam into the drum, *A*. The sides of the skeleton boiler are also formed by inclined water tubes, *H*, extending between end headers, *I*, these end headers being nippled into the top and bottom cross boxes, D_1 and *F*, at the rear and in the cross box, *C*, and drum, *A*, in front. The superheater is composed of a series of approximately vertical boxes, *K*, located at one end of the boiler, the boxes being connected alternately to inlet pipes, *L*, into which is led from the various boilers supplying it the steam requiring to be superheated and to outlet pipes, L_1, and having expanded into their inner walls a series of U-shaped superheating tubes, *M*, one limb of each tube being connected to one manifold and the other limb to the adjoining manifold. The superheating tubes, *M*, protrude between the rear uprising water tubes, *E*. The combined superheater and boiler is enclosed in a metal casing, *Q*. The superheater and boiler elements are supported over a furnace chamber, *N*, fitted with a firegrate, *O*, and firing door, *P*. The furnace gases pass up between the rows of water tubes, *D*, and circulates around the superheater tubes, *M*, and escape upward between the steam and water tubes, *G*, to an uptake or chimney, *R*. The fiercest heat of the furnace gases is reduced by their impingement on the rows of tubes, *D*, which absorb part of the heat, and the superheater tubes, *M*, are thus subjected to the action of the gases at a lowered temperature, which increases their durability. We are indebted to the London *Mechanical Engineer* for the above description.

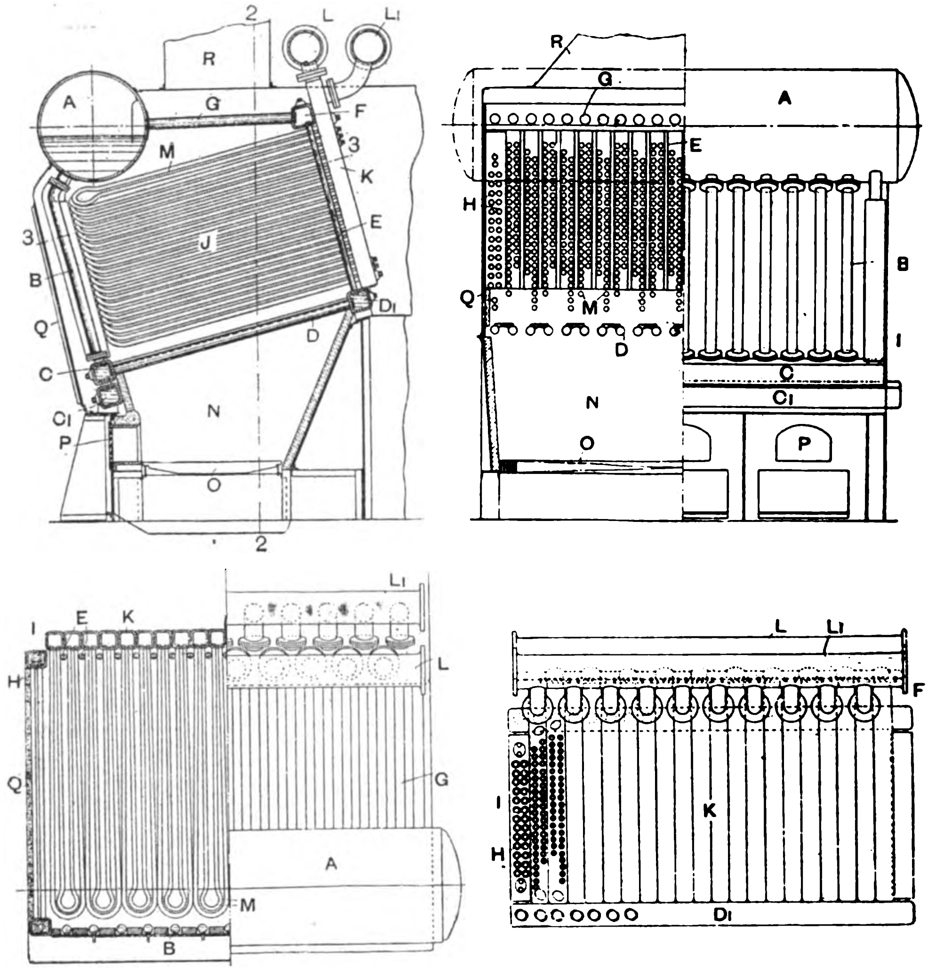

FIG. 3.—COMBINED SUPERHEATER AND WATER-TUBE BOILER.

Suction Producer Gas Engine.—Figs. 4 and 5 herewith taken from a recent issue of the London *Mechanical Engineer* shows a design of gas engine for working in conjuction with suction gas producers. The object of the design is to control the engine so that, notwithstanding great and rapid variation of load, the suction producer is always kept in a sufficiently active state at light loads as to immediately respond to the increased consumption of gas required at heavy loads, and further to provide an attachment to gas engine governors which permits the governor to be arranged for rapidly varying loads or slowly varying loads. The invention consists, broadly, in causing the engine to always draw gas from the producer at least at a minimum rate, this minimum rate being such as will maintain a sufficient incandescent zone in the producer ready to meet sudden increases of load, and also in a governor applied to a suction producer gas engine, which governor cuts off the gas supply to the engine to the lowest point which can be safely done without allowing the producer to cool, and when that point is reached governs the engine, not by further reduction of the supply of gas, but by operating on the igniting device to prevent ignition taking place. The engine thus continues to draw through the producer the minimum amount of air required to keep it in a condition to become fully active instantly when required. Referring to Figs. 4 and 5 there is produced in the air and gas valve casing a bypass *A* leading from the gas passage *C*, so that when the gas valve *D* does not open the engine still draws a certain quantity of gas through *A*, sufficient to maintain adequate incandescence in the producer to enable the latter to instantly respond to a sudden increase of load on the engine. In the bypass *A* a cock *E* is provided, fitted with a handle *F* by which it may be set. The air valve is shown at *G*. The gas valve *D* is controlled by the device shown in Fig. 5, consisting of a step-die-piece, *H*, which operates in conjuction with a pecker *I* and cam to vary the admission of gas during the working stroke of the engine. The die-piece is carried by a rod *J* from one end of a lever, *K*, pivoted at *L*, and operated upon by the governor, which raises the die-piece *H* more or less according to the speed of the engine, the die-piece being stepped as shown in order that the uniform operation of the pecker *I* may impart a correspondingly less or greater lift to the gas valve, the spindle end of which is indicated at *M*. The gas valve casing is arranged by means of a bypass to always allow at least a sufficient amount of gas to be drawn from the producer to maintain adequate incandescence. When the die-piece is removed to a predetermined limit, further governing of the engine, if required, is effected by retarding or cutting out ignition. In Fig. 5 ignition is cut out by an extension of the governor lever or by a lever *N* secured thereto and pivoting about the same pin *L*. The end of the lever *N* carries a pin *O* adapted, when the governor sleeve attains a certain position, to move into contact with one end of a lever *P*, tilt the latter about its pivot, *Q*, and so interrupt the current at the contacts *R S*, the latter of which is fixed, both contacts being in the ignition circuit. Gas is therefore drawn into the engine without ignition occurring.

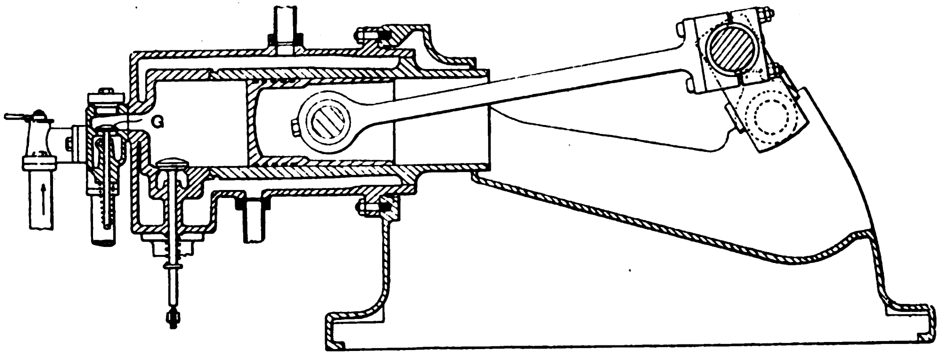

FIG. 4.—SUCTION PRODUCER GAS ENGINE.

Artificial Loads for Electric Generators.—H. C. Davies, in a recent article in the London *Electrical Engineer*, discusses the question of artificial loads for dissipating electric power. An artificial load is an obvious necessity with the comparatively large sets in use at the present day, due regard to liability and freedom from risk necessitating the trial running of the set at something approaching full load for a short time after a repair of anything but a trifling nature has been performed. This is especially the case in alternating works, owing to synchronizing difficulties. In a surprisingly large number of works tubs are used as artificial loads, but they are both impracticable and expensive and in alternating and direct-current works of any size it will be found to pay to install properly designed permanent water loads, the apparatus being simple and inexpensive. The passage of a current through water produces heat; as the boiling point is approached the resistance decreases markedly. For convenient working the water must be constantly renewed in order to maintain its temperature. The nature and supply of the water must also be considered, as the resistance is apt to vary greatly. While the water load is undoubtedly the best and handiest medium for testing, there are other types in use which may be recommended for purposes apart from machine testing. The carbon rheostat was one of the first power absorbers and has done excellent service. The best form is made up of a series of carbon plates in a frame fitted with a screw for tightening up or slackening back, the contact between the plates being increased or diminished and the resistance of the whole varied in proportion. In this form the resistance is due not so much to that of the carbon itself as to the more or less bad contact between the plates. Cooling is the chief difficulty presented by this apparatus and for this reason it is more suitable for small powers than for large. A handy, inexpensive form of artificial load may be made up of galvanized-iron netting wound in a spiral, using non-inflammable insulating distance pieces, or by folding backward and forward over an iron frame built up on insulators. This is valuable for testing small machines such as exciters. Iron netting, especially that having a right-angled mesh, is an excellent dissipator of heat, one set of wires carrying current, while the other, at right angles, conducts away much of the heat. Expanded metal also makes an effective resistance and in many ways is preferable to netting, being stronger and requiring less supports.

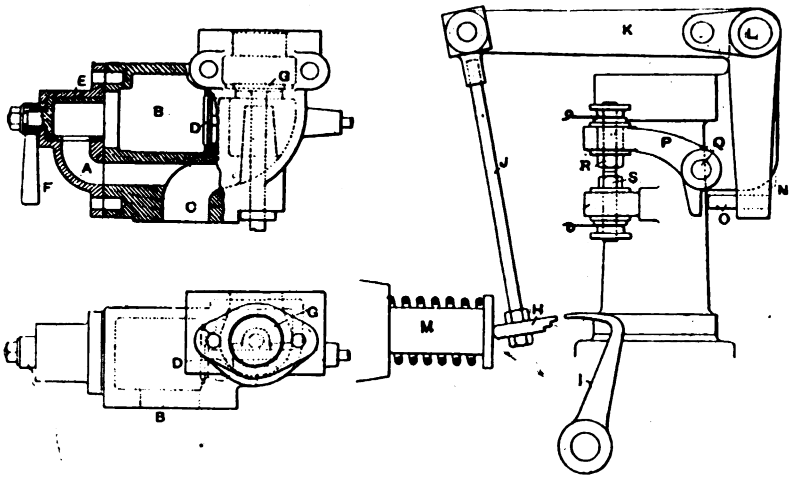

FIG. 5.—DETAILS OF SUCTION PRODUCER GAS ENGINE.

The Standardization of Electrical Machinery.—London *Engineering* contains the interim report of the sub-committee of the Engineering Standards Committee on generators, motors and transformers, dealing with the principal conditions with which it is desirable that these articles should conform. The committee determined not to risk hampering the trade with standard dimensions and shapes which might easily become obsolete as designs improved, but confined themselves to the more immediate necessity of securing uniformity in pressures and frequencies, rating of plant and conditions of test. The standard voltages recommended are as follows:

Alternating or direct-current, at the terminals of the consumer	110, 220, 440 and 500 volts
Alternating current at the generating terminal	2200, 3300, 6600 and 11,000 volts
Standard pressure at primary terminals of alternating-current transformers	2000, 3000, 6000 and 11,000 volts
Standard pressure at secondary terminals of alternating-current transformers	115, 230, 460 and 535 volts at no load
Standard pressure at teminals of direct-current traction motors	500 volts

A variation of 10 per cent. either way is permitted in the above figures, so that plants built to the standards recommended may be employed on the great majority of the existing systems, although it is hoped that in course of time such latitude will become unnecessary. For alternating current a frequency of 50 periods per second is to be adopted as the standard, although in special cases, where a lower frequency is advisable, a secondard standard of 25 cycles is allowed. The difficulties in connection with the rating of generators and motors have been met by dividing the machines into two classes, according as they work continuously or intermittently. Machines of the former class must be capable of giving the rated output continuously for six hours, and the latter for one hour. When not otherwise specified, continuous working is always to be understood, and every machine is to bear a name-plate giving such particulars of the output, voltage, frequency, revolutions per minute, exciting current and power factor, as bear upon its particular type. The output of generators is to be measured in kilowatts, and that of motors in brake horse-power. Direct-current generators are in future to be made in six standard sizes—from 6 to 100 kilowatts, inclusive—and a suitable speed has been recommended for each size. From 100 to 1000 kilowatts, inclusive—there are nine sizes—machines up to 250 kilowatts having two alternative standard speeds, while above this size an additional slow speed is added, making three speeds in all. Alternating-current generators are required to give a sine wave as nearly as possible under all conditions. The field excitation for simple alternators should be at either 65, 110 or 220 volts. The variation of pressure at the terminals between full load and open circuit under the same conditions of speed and excitation must not exceed 6 per cent of the normal on a non-inductive load, or 20 per cent on a load with a power factor of 0.8. Motors are classified as open, protected, ventilated or totally enclosed, a "protected" motor being one in which the interior is shielded from accidental contact without interfering with the ventilation; and a "ventilated" motor, one in which, although ventilated, access to the interior is only possible by opening or removing the casing. Direct-current motors are standardized in 15 sizes, from ¼ to 100 brake horse-power, inclusive; single-phase motors in 11 sizes, from 1 to 25 brake horse-power, and two and three-phase motors in 17 sizes, from 1 to 100 brake horse-power. The speeds at full load are given for every size; and in the cases of alternating-current motors the figures are the synchronous speeds at no load, and a reduction of speed from 7½ per cent in the smaller sizes to 2½ per cent in the larger at full load must be allowed for. In connection with the work of the committee, experiments are being carried out at the National Physical Laboratory to determine the safe temperature rise allowable in the coils of dynamos and transformers. The results are not quite ready for publication, although the report indicates that they will be of considerable value, and will result in the recommendation of higher temperatures than have been advised by either the German or American standardization committees. Meanwhile, it is of interest to note that the temperature of the hottest part of a coil, as determined by measurements with a thermo-couple, never exceeds the mean temperature of the coil, by more than 25° C.

SOME RECENT ELECTRICAL PATENTS

Securing Armature Coils.—For several years past, many builders of dynamo-electric machinery have used strips of insulating material driven into grooves in the armature teeth just below the tooth-heads to hold the armature coils in the slots of slotted cores; these strips have heretofore extended the full length of the coil slots and projected slightly at each end of the core, covering the embedded part of the winding completely. The grooves in the sides of the teeth reduce the cross-section of the magnetic path at that point, of course, so that in some cases the teeth are more highly saturated than at the roots. In order to obviate this disadvantage, Isaac De Kaiser proposes the arrangement shown in the accompanying illustration and has secured a patent on it. It consists merely of short retaining strips, 7, in short grooves, 6, one at each end of each coil slot, instead of a long strip throughout the whole length of each slot. The core discs between the inner ends of the retaining strips are not grooved; the restriction of the magnetic path on account of the retaining strips, therefore, is confined to a few teeth at each end of the core. Although the inventor does not mention it in his specification, the better ventilation obtained by this arrangement as compared with long strips covering all of the embedded part of the winding is probably a greater advantage than the one claimed. Patent No. 756,228.

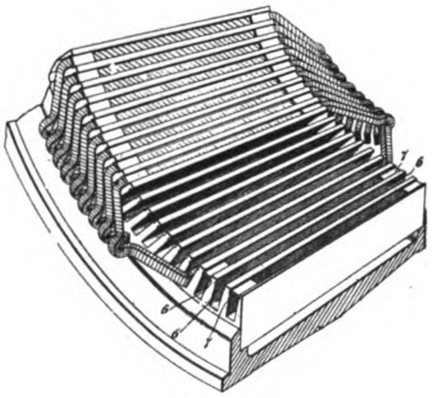

FIG. 1.—ARRANGEMENT FOR SECURING ARMATURE COILS.

Telephone Receiver.—Fig. 2 illustrates a form of telephone receiver invented and patented by Ernst Gundlach, the object being to increase the effectiveness as compared with a receiver of ordinary construction embodying the same quality of materials. The fundamental feature of the invention is the application of spring pressure to the rear face of the diaphragm, this being said to increase the speaking efficiency of the instrument. The diaphragm is pressed away from the magnet by means of a dished metal disc, *C*, a plan view of which is given by Fig. 3. To the center of the diaphragm is attached a soft iron plug, *b*, which projects into the bore of the magnetizing coil and is almost in contact with the stationary soft iron core, *v*, attached to the permanent magnet, *D*. The latter is supported by a circular cup, *E*, held in place by the receiver cap along with the diaphragm. The tension disc, *C*, presses against the diaphragm about half way between the center and the periphery. Patent No. 762,820.

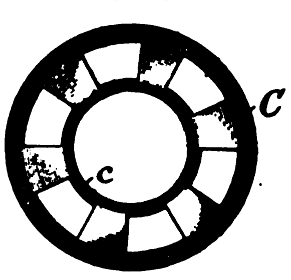

FIG. 3.—PLAN OF METAL DISC.

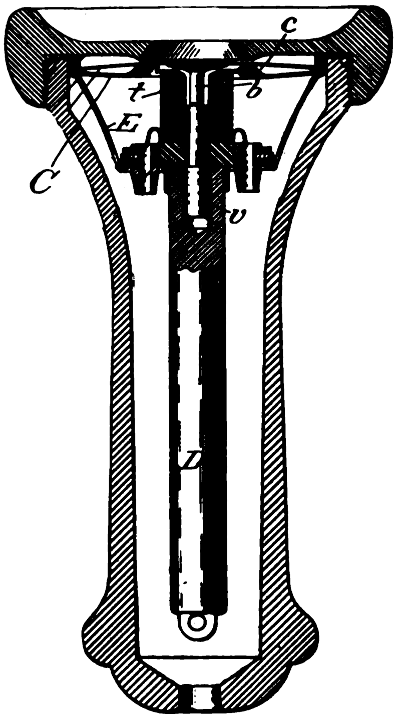

FIG. 2.—SECTION OF TELEPHONE RECEIVER.

Gasoline Motor Car Design.

To the Editor American Electrician:

I wish to bring to your attention an error in the drawings for an automobile in the July number of The American Electrician. In the detail drawing of the brake-shoe, Fig. 26, on page 253, the hole for the pin which attaches it to the brake pedal is at right angles to the position it should occupy. This will be readily seen by reference to the plan view of the chassis on page 349. Of course, the lug which carries the hole would also have to be turned around; this would involve a slight change in the shape of the casting. Probably others among your many subscribers have already noticed it, but I thought I would mention it as a brake-shoe made according to the detail drawing would be absolutely useless.

Dorchester, Mass. H. K. Spencer.

[It is not intended that the brake-shoe shall be pinned directly to the brake pedal. A link is intended to be used to connect the two, the holes in the ends of the link being drilled at right angles to each other: unfortunately, this was omitted in the description and drawings.—Editor.]

Single-Phase Wattmeter Construction.

To the Editor American Electrician:

In the August issue of the AMERICAN ELECTRICIAN the "Abstracts from Foreign Contemporaries" contains an item with the heading, "Single-Phase Wattmeter," taken from *L'Industrie Electrique*. With reference to the motor system described in this item, I beg to say that as far as the shunt or potential circuit is concerned, it embodies the same principles that have been used for a number of years in induction wattmeters built by the Stanley Instrument Company. This method of phase adjustment is covered by United States patent No. 658,815, issued to William Stanley, which describes a means for lagging the current in the potential circuit by means of the shunted magnetic circuit or magnetic bridge. This same scheme of a magnetic shunt or magnetic bridge is shown in the sketch, Fig. 16, in the item above mentioned.

E. W. GOUGH,
Stanley Instrument Company,
Great Barrington, Mass.

◆◆◆

NOTES.

The Association of Edison Illuminating Companies will hold its twenty-fifth annual meeting at the Hotel Wentworth, New Castle, N. H., beginning Tuesday, August 30. A number of extremely interesting and valuable papers are promised.

Power is the title of a handsome booklet issued by the South Bend (Ind.) Electric Company and containing a strong argument for electric power. Progressive central station men will find the book at least interesting and perhaps valuable as a suggestion for similar things from their own standpoints.

The Telautograph for Office Work.—The Prudential Insurance Company has installed a telautograph system as a means of communication between its cashier's office and policy loan department. Presumably, the use of this class of apparatus was chosen in order to have records of instructions without the risk of inaccuracy involved by having typewritten records made after instructions had been transmitted verbally; otherwise an interior telephone system would appear preferable.

Combined Central Station and Municipal Plant.—At Wausau, Wis., the perennial question of municipal ownership *vs.* central stations has been solved in a manner which appears to be well worthy of consideration in other localities. The city is going to install, maintain and handle the distribution system and street lamps, buying current from the central station company which, presumably, will be allowed to install a distribution system for private service. The lamps are to be 420-watt alternating enclosed arcs, taking 6.6 amperes and operated in series.

Special N. E. L. A. Train to St. Louis.—The National Electric Light Association has decided not to hold a convention at St. Louis during the Exposition period, but arrangements have been made for a special train from New York for association members who wish to attend the International Electrical Congress. This train will leave the Grand Central Station, New York, at 1 p. m., September 10. Full particulars may be had from Mr. Alex. Henderson, 527 West Thirty-fourth Street, or Mr. George F. Porter, care National Electric Light Association, 136 Liberty Street, this city.

Lectures at the New York Trade School.—Following the usual custom, a series of evening lectures on steam and electrical engineering will be given during the coming fall and winter at the New York Trade School, First Avenue, Sixty-seventh and Sixty-eighth Streets. These lectures are intended for practical workers, stationary engineers, firemen, electrical workers and machinists. They represent an attempt to supply the need for practical information, and explanations of phenomena and experiences in daily work. The lectures take more of the nature of a conversation between the lecturer and his hearers, and questions are freely asked and explanations given, accompanied by illustrations and, where possible, by experiments. The main object of this course is to present in a simple and easy way, to men of practical experience, the reasons for the laws upon which their work is based, and explanations of the phenomena that have led to the formulation of these laws. The cost of attending each of the courses on Steam and Electricity is one dollar. Information as to dates and arrangements can be had upon application to H. V. Brill, superintendent, New York Trade School, Sixty-seventh Street and First Avenue, New York.

Trial of the Arnold Single-Phase Railway System.—On August 3 an interesting test of the Arnold electro-pneumatic railway system was made on the tracks of the Michigan Suburban Railway Company, at Lansing, Mich. In this system, a single-phase motor is used, the armature of which is always in motion. In starting, stopping or at any speed short of that corresponding to the synchronous speed of the motor, the field also revolves and drives, or is driven, by a compressed air engine. In the former case energy is stored as compressed air in a tank, and in the latter case is given out. By this means not only can a car be operated at any speed by the employment of single-phase current, but a constant load is kept on the power house.

The trial was made with the car equipment which was partly destroyed last winter in a fire which burned down the car barn where it was stored, the fire occurring a few days prior to the date set for a trial of the system. The machinery had been partly repaired, but owing to cracked castings a complete demonstration was not possible on the trial. The object was to determine, as far as the damaged apparatus would permit, the control of the system and the taking of current from the trolley at 6,000 volts. The car at times attained a speed of 25 miles per hour, and no difficulty at all was experienced even at this speed in taking current from the trolley. Mr. B. J. Arnold, the inventor of the system, who was present at the trial, expressed himself entirely satisfied with the control which enabled speeds from the lowest to synchronism to be maintained and was very satisfactory in retarding and accelerating.

The Temperature of Boiling Water.—No doubt everyone who has occasion to use the ordinary Fahrenheit thermometer to any serious extent has at one time or another asked himself why the boiling point of water is marked 212°; and at first sight it does seem a somewhat stupid number to use as compared with the round 100° adopted on the scale of the Centigrade instrument used in France. Like many other apparently stupid things, however, the 212° had its origin in a desire for simplicity and permanence, and has become stranded on the rocks of inconvenience as a result of the world's wider knowledge, and aptly illustrates the danger of setting limits to its range. Fahrenheit, who first introduced the thermometer which bears his name, was familiar with the effect of a mixture of powdered ice and salt, which was then regarded as the very ultimate limit of cold obtainable, and made this his zero, in the expectation that it would serve for all time. Seeking for some fixed and equally convenient point which should serve as his upper datum, he fixed on the temperature of human blood as a point which remains unvarying for all generations, and made this his 100° mark (though it was subsequently found that his measurement of this point was slightly inaccurate, blood temperature being about 98½°). This scale of graduations, it will be evident, was from Fahrenheit's point of view and limited knowledge quite as rational, in fact identical in principle, with that adopted by Celsius for the Centigrade thermometer. Continuing the graduations upward beyond Fahrenheit's 100° or blood temperature mark, it became purely a matter of registration that the temperature of boiling water was 212°. The primary range, viz., that between the temperature of an ice and salt mixture and human blood, was 100°, and Fahrenheit's mistake lay in assuming that his zero was the absolute one. The Centigrade scale, with the freezing and boiling points of water as the upper and lower limits, certainly seems more rational for most ordinary temperature measurements, but the average person is apt to forget that it is only conventional, and that for purposes of exact measurement the physicist must refer his phenomena to the absolute zero, where temperature ceases to exist, where hot and cold have no meaning, and every form of matter is devoid of motion and is utterly dead. This is the only real zero of temperature.—*Vulcan.*

ESTABLISHED 1889.

American Electrician

A Journal of Practical Electrical and Steam Engineering.
WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Published on the first of each month by the
McGraw Publishing Company,
114-118 Liberty Street, New York.
Telephone Call, - - - 7606 Cortlandt.

Branch Offices:
Philadelphia: 929 Chestnut Street.
Chicago: Monadnock Block.
Cleveland: Cuyahoga Building.
London: Hastings House, Norfolk St., Strand.
St. Louis Headquarters:
Section 1, Electricity Building,
Louisiana Purchase Exposition.

Address all business communications to
AMERICAN ELECTRICIAN.

Copyrighted, 1904, by McGraw Publishing Co.

Entered at the New York Post Office as second class mail matter.

Subscription, - $1.00 Per Year
In the United States, Canada and Mexico.
FOREIGN COUNTRIES, $2.00.

NOTICE TO SUBSCRIBERS.

Subscribers will find on addressed wrappers of their papers the date on which their subscriptions expire. This is the only method of acknowledging the receipt of subscription payments.

In requesting change of address both the **old** and the **new** address should be given.

NOTICE TO ADVERTISERS.

Changes in advertisements should reach the office of the American Electrician by the 15th of each month in order to appear in the following issue. New advertisements can be received up to the 25th of each month.

Vol. XVI. SEPTEMBER, 1904. No. 9

The American Electrician has a larger paid subscription list than any other electrical journal in the world.

The New Single-Phase Railway System.

Elsewhere in this number will be found a brief description of a single-phase railway equipment which cannot fail to be of vital interest to all concerned in electric traction. Like many other highly important developments, the new motor is remarkable chiefly for its simplicity and conformity to well-recognized principles. The bugaboo of armature reaction is disposed of by the familiar expedient, adopted by Prof. Ryan in direct-current work, of practically surrounding the armature by distributed stationary windings having a magnetomotive force more than sufficient to neutralize that of the armature winding. The main field winding is also distributed, so that the field magnet structure is very similar to that of an ordinary induction motor. The armature is in all visible respects similar to that of a direct-current motor. This, of course, is not the whole story; while the machine is very simple as a net physical result, its successful design must have involved tedious and most painstaking investigation and analysis in order to attain satisfactory compromises between opposing factors.

The plan of exciting the "compensating" winding by means of the main or working current—connecting the winding in series with the armature—instead of by means of induced currents, confers the inestimable advantage of dual operation; the motor works just as well on direct current as on alternating—or even better—and by means of a suitable transformer a car can be operated on any alternating trolley voltage. Cutting out the transformer and putting the field windings all in series leaves the car equipment ready for work on any standard direct-current trolley line. This feature disposes of one of the most serious, if, indeed, not the chief, objection hitherto urged against alternating-current traction in this country. With a "universal" car equipment, operating companies are in position to retain their direct-current systems for congested centers and to use high-voltage alternating current for outlying districts, long interurban links, etc.

Joint Steet Lighting Plants.

In another column will be found an interesting item of news to the effect that in Wausau, Wis., it has been decided to try joint ownership and maintenance as a solution of the vexatious problem of street lighting economics. The company owning the central station is to operate it and supply curent to the arc-light circuits at so much per kilowatt-hour; the city is to own the pole lines and lamps and keep them in operative condition, just as the owner of a printing office or other industrial establishment does with regard to his motor or motors. This arrangement appeals to one strongly on first consideration. There will, of course, develop sources of contention, but we can think of none which cannot be disposed of efficiently and permanently, provided neither side is abnormally stubborn and unreasonable. Many of the widely experienced central station managers have long held the opinion that the maximum of satisfaction to both the company and the consumer is obtainable with the minimum of friction and worry when the company rigidly restricts its commercial activity to the supply of current, exercising, of course, reasonable supervision over the customer's policy in the matter of selecting his lamps, motors or other apparatus, in order that dissatisfaction may not arise from grossly inefficient translating devices.

Considered in the abstract, there is really no reason why a municipality should not bear the same relation to the operating company that the smaller consumers bear. A lighting circuit and complement of lamps is at least of as much value to the city as to the company, and the municipal ownership of the complete street outfit should very largely simplify the relations between the two interests. Most towns of any importance have their own fire departments, and the care and maintenance of the street lighting circuits might be combined with the same attention to the alarm circuits and apparatus with considerable advantage in both directions. A somewhat higher grade of technical skill is required for the repair of arc lamps than for the maintenance of electric bells, batteries, etc., and the same is true of arc lighting and fire-alarm circuits, respectively. Given a staff of employes competent to keep the lighting system in good condition, therefore, the fire-alarm system would in all probability receive more effective care than it usually does now. Moreover, much work would be feasible in the local repair room that is now sent out and done at relatively high cost. The combined supervision of the two systems, however, is by no means the limit of advantage derivable from the municipal ownership of the street lighting equipment; the many other possible benefits will readily be apparent to those who have had experience with obstreperous city councils.

The Passenger Elevator.

Within the past few months there has been an unusually large amount of discussion of hydraulic *vs.* electric power for operating passenger elevators, and some rather labored arguments have been offered in several instances to show the great superiority of the hydraulic system. The chief weakness in most of the arguments lies in comparing the ideal hydraulic system with the actual electric system; bringing out strongly the inherent advantages which ought to be realized by the use of water and setting these up against the well-recognized practical shortcomings of electrical systems as developed in every-day service. It seems to us that advocates of the hydraulic elevator would make out a much stronger case if they were less partisan; certainly those who are at all familiar, not with the constructional details but with the actual results obtained in practice, would be more favorably influenced by the claims made for the hydraulic system if those claims were less prejudiced and agreed more closely with one's observation.

The hydraulic elevator has several advantages which are realized in practice. The chief advantages are: (1) The prime mover has a reciprocating motion corresponding with that of the car, so that acceleration to a high speed is obtainable with less complexity and greater smoothness of operation; (2) the operating medium is inelastic, rendering braking unnecessary and thereby decreasing the risk of accidentally dropping the car; (3) overloading the car before trying to start from the bottom of its travel cannot damage the system nor cause delay by the operation of safety devices. The chief disadvantages are: (1) Serious inefficiency, the same quantity of water being required to lift the empty car that is used to lift the maximum load; the car cannot be over counterbalanced, which also lowers the efficiency; (2) the apparatus occupies very much more valuable space than that of the electrical system; (3) when repairs to the elevating mechanism proper are necessary, they are more difficult to make, being usually of a character requiring the application of considerable physical strength in very close quarters.

The principal advantages of the ordinary forms of electrically operated elevator are: (1) Very high all-day efficiency due to the facts that the power taken by the motor is roughly proportional to the total load and that the car is over counterbalanced about 50 per cent.; (2) the apparatus is all concentrated near the elevator shaft, rendering the location of trouble easy; (3) parts damaged by accident may be replaced with great facility. The disadvantages of importance are the delicacy of the control mechanism and the absence of the advantages noted for the hydraulic system.

It is frequently claimed that the hydraulic system is more rugged and therefore requires less repairs than its electrical rival; this is undoubtedly true of the control mechanism alone, but not necessarily true of the main apparatus. We have observed many instances of hydraulic installation one part or another of which was in trouble most of the time; one of these consisted of a bank of five elevators, of which one-fifth was out of commission more than 30 per cent of one year. The claim is also made now and then that the hydraulic machine is safer because it has inherently positive travel limits: the piston cannot travel more than its full stroke. It does not require vivid imagination to predict what would happen if the valve became jammed wide open upon starting the car from the bottom of the shaft; the "positive limit" of travel at the piston would not make the occupants of the car more comfortable after the latter arrived at the top of the shaft.

There is no question that each system has its legitimate field of operation in which it is distinctly superior to its rival, so that broad claims of greater advantages for either of them are absurd. We are firmly convinced, however, that the full possibilities of the electric elevator have by no means been utilized. That it is not, or cannot be, adapted for high-speed work we refuse to believe, and there seems to be no insuperable obstacle to its successful competition with water power in this field. The development of the hydraulic elevator appears to have reached it ultimate limit, if one might be so rash as to say that of any branch of engineering; the electrically operated system, however, should certainly be capable of better things than have thus far been demonstrated.

Frequency and the Induction Motor.

It is often stated, without the proper qualification, that the cost of building a high-frequency induction motor is lower than that of a machine built for a lower frequency. This is universally true of a transformer, but in the case of the induction motor the question of speed modifies the foregoing statement importantly. If the number of poles remains the same, then a high-frequency motor costs less than one for lower frequency; the fact that the speed is directly proportional to the frequency, combined with the knowledge that high-speed machines of any type cost less than those operating at low speed, is sufficient explanation of the relation between costs with the same number of poles. But it is almost generally overlooked, except by designers, that for the same number of revolutions per minute, an induction motor of given output and frequency costs more money than one of the same output and a lower frequency. This is because a greater number of poles is required at the higher frequency, which necessitates a larger diameter of machine. Another point ordinarily overlooked is that high-frequency machines necessarily have lower power factors than those built for lower frequencies. Taking into consideration the requirements of central station work and the foregoing facts, it would seem that 35 or 40 cycles is preferable to any higher figure for general service plants. Lower frequencies render illumination by incandescent lamps unsatisfactory and even dangerous to the eyes.

Sources of Electrical Fires.

A letter from one of our readers, which is published this month, contains suggestions as to the actual causes of electrical fires which are well worthy of concentrated thought. A perusal of the last quarterly report of the National Underwriters' Electrical Bureau will show that a large proportion of the fires caused by electricity during the three months covered by the report was due to crosses, disarrangements of circuits and similar abnormal conditions against which no set of construction rules can effectually provide unless they be made so stringent as to work unnecessary hardship upon most manufacturers and contractors. The personal element is so important and widely variable a factor that a code of rules adequate, even by rigid enforcement, to protect against the multitudinous vagaries of human nature would probably rival the Encyclopædia Britannica in bulk. The moral of this brief homily is that until human beings become absolutely conscientious and infallible, electricity, like all other forces and powerful agents, will continue to be a source of danger to a highly unnecessary extent.

HOW TO MAKE A HIGH-VOLTAGE TESTING BATTERY.

BY GEORGE T. HANCHETT.

In testing insulation a common method is to measure it directly by means of a Wheatstone bridge and a few batteries. Those who have had practical experience with such test know that the results are practically worthless because the insulation is not subject to an electric pressure at all commensurate with that which it will have to stand in practice, and, furthermore, insulation resistance is by no means a constant quantity, but is a very irregular function of the pressure. At 2 volts it may be several megohms, at 100 volts perhaps a megohm, at 500 volts only 500,000 ohms, and at 1000 volts a short-circuit may develop.

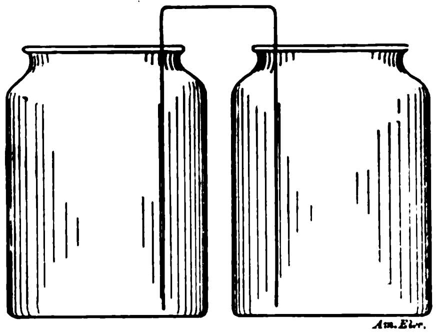

FIG. 1.—ARRANGEMENT OF CELLS.

It is conceded that the only practical way to test insulation is to subject it to a pressure of at least 100 volts and preferably more, and to measure the current flowing, which is conveniently done by means of a voltmeter, the formula being

$$R = \frac{(E - V)\, r}{V},$$

where E is the line potential, V is the reading of the voltmeter, and r is the resistance of the voltmeter. If there is a short circuit V is equal to E and the insulation resistance is O. If V is zero, the insulation resistance is infinitely high, and if it is an appreciable amount the insulation resistance appears in ohms.

In order, however, that this test shall be reliable, the source of potential should be at least 100 volts, and preferably more, and in testing armature coils it is much better to use 1000 volts. But it is advisable that the means of producing this potential shall be such that in case a short-circuit does occur the damage will be limited to the point of break-down and will be in any event very small. In other words, we must have a source of potential which will "lay down" when an appreciable current is drawn from it. In alternating-current work this is conveniently obtained by the use of a very small transformer, but alternating current is not always available and small transformers with high voltage coils are usually special and sometimes not to be had. Moreover, in alternating current work the voltmeter test is not convenient because the deflections are sometimes very small and on small deflection work an alternating current voltmeter is very deficient.

A convenient source of direct current at high voltage and small current capacity can be obtained by the use of a storage battery of many cells. These cells can be so cheaply constructed and so readily arranged and charged, and they are so nearly indestructible, that they are well worth the trouble. The cells are best made of small, wide-mouthed bottles which can be bought for a fraction of a cent apiece of any dealer. One-half as many bottles as volts will be required. The elements in the cells are simply strips of ordinary commercial sheet lead, which should be cut to fit the mouth of the bottle conveniently and bent into U shape so that the legs can be inserted in two bottles placed close together side by side and will just clear the bottoms of the bottles, as shown in Fig. 1.

The cells are conveniently arranged in banks of 50 each, which will enable them to be readily charged in multiple from a source of potential 110 to 115 volts. They can then be connected in series, and 10 such banks will give a potential of 1000 volts. A wooden frame made of strips of half-inch lumber, as shown in the photograph, makes a convenient support for such cells and can be equipped with binding posts along the side members, which will allow the cells to be conveniently connected in series or multiple.

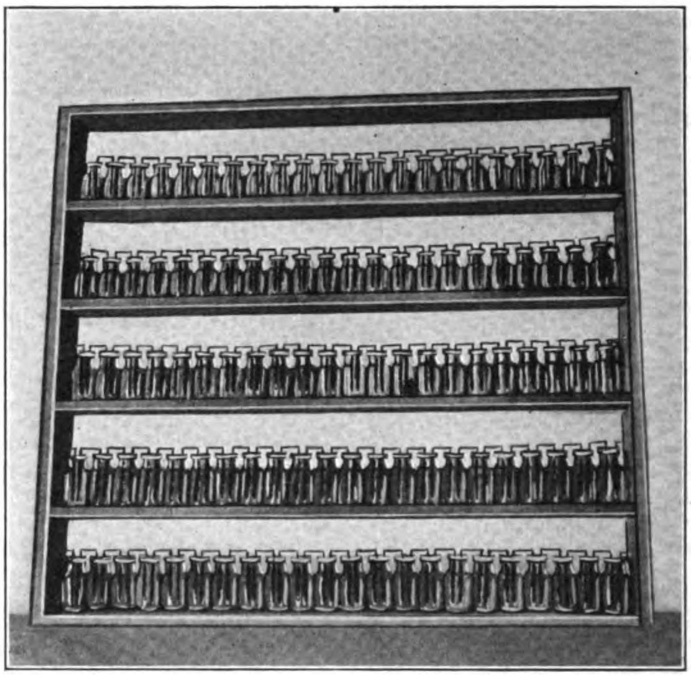

FIG. 2.—HIGH-VOLTAGE TESTING BATTERY.

The formation of the plates of these cells will give some trouble unless certain precautions are taken. If it is attempted simply to put the lead plates in the bottles, fill the latter with storage battery solution and charge, the cells will fill with a fuzzy brown deposit which will quickly bridge across from plate to plate and give a great deal of trouble; moreover, their capacity will be very limited. They will almost immediately lose their voltage as soon as they are disconnected from the charging mains. In order to form such cells properly, the cells should first be filled with clean water and a drop of nitric acid put in each bottle; then the banks of 50 cells each should be connected in multiple and connected to the 110-volt circuit. A tree-like crystal deposit will immediately form on the plates and rapidly bridge across them; this will be very flimsy in its structure and readily detachable. Half an hour of charging will thoroughly oxidize the plates and cut off any grease which may be on them. They should then be removed from the cells and all the loose deposit shaken off, and the bottles themselves should be emptied, thoroughly cleaned and filled with storage battery solution, that is to say, acidulated water of about 1.200 specific gravity.

On reassembling the cells they should be connected to the mains again and charged, and after the positive plates have shown a distinct brown, they should be discharged into a bank of lamps and connected up the *reverse* way and charged again. This should be repeated some ten or fifteen times. The formation of active material becomes deeper and deeper as the process proceeds. It will be found that 15 minutes' charging will suffice to completely reverse the cells. After these reversals have been made for a sufficient number of times to form a good coat of active material, the cells should only be charged in one direction whenever they are used. They will lose their charge over night, but they can be readily charged in half an hour, and once charged will deflect a voltmeter steadily for an hour or more, after which 10 or 15 minutes' charging will refresh them so that they will be good for another hour. As voltmeter currents are the only currents to be drawn from such a battery they will be found amply sufficient for test work.

The only attention that the batteries require is an occasional filling with water, and charging when necessary, and they are a very useful source of electromotive force for insulation tests and voltmeter calibration. The photograph shows a bank of 110 cells arranged for such work. The cost of material for a complete outfit of 500 cells should not exceed $10.00.

BOILER ROOM MANAGEMENT.

BY WALTER W. EDWARDS.

It is a noticeable fact that the major portion of the questions asked of applicants for license pertain to the handling of boilers. The reason for this striking feature of such examinations is not far to seek. It is in the boiler room rather than the engine room that the possibilities of widespread destruction and disaster lie, ready to break forth at the first careless oversight on the part of the engineer. A wrong move in the engine room may mean a few hours delay or a few dollars in damage, but with the exception of fly-wheel accidents, there are none of the terrible possibilities, which occasionally become facts in the engine room that there always are around boilers, hence the examinations for license are always framed so as to thoroughly test an applicant's knowledge of boiler management.

In this article it is assumed that an engineer has been given charge of a battery of boilers that has been idle a few days, with orders to get it ready for steaming, say a week later. Under such circumstances and with such orders, a thorough and capable engineer would trace each pipe and connection in order to see exactly where it leads, what valves there were in it, and whether or not it was leaking at any point or was otherwise in bad condition. The valves especially should be examined to see if they are leaking or in need of packing. An experienced eye will at once detect a leak around a valve stem from the peculiar coloring and dirt due to the blowing of steam, but whether a valve allows steam or water to leak through when it is closed is not so easily told by an examination when the pressure is off.

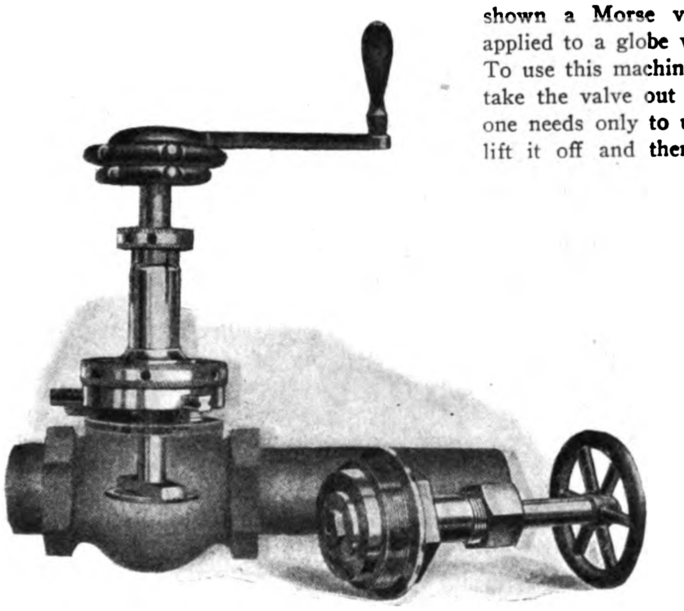

FIG. I.—VALVE RESEATING MACHINE.

The best course to pursue with ordinary disc valves is to remove the bonnet of the valve, and then carefully examine the surface of the valve disc where it comes in contact with its seat. If at any point it is seen that the surface is not bright in a continuous band all the way around the beveled edge of the disc, it may be safely assumed that the valve leaks. To repair such valves it is often only necessary to grind the valve in; this is done by first cleaning the valve and valve seat with spirits of turpentine and a handful of waste and then covering the bearing surface of the valve with a little lubricating oil and ground glass, after which the disc is replaced and turned back and forth on its seat until the high places are ground down and the disc bears evenly all around. The disc may be turned on its seat by tightly wedging a wooden piece in between the lugs on the top of the valve where the valve stem goes, in such a manner that it extends up from the valve so that it can be grasped. In grinding in a valve care should be exercised to turn it around every minute or so in order to prevent wearing the disc or seat more at one point than another.

If the valve is deeply cut or scored at some point on either the disc or the seat, it would mean too much labor to grind the defect out, and in such a case recourse must be had to a reseating machine, several of which are on the market. In Fig. 1 is shown a Morse valve reseating machine applied to a globe valve having a flat seat. To use this machine, it is not necessary to take the valve out of the pipe line at all; one needs only to unscrew the bonnet and lift it off and then place the machine in position as shown. The chuck that holds the machine in place is provided with stepped jaws; by turning the cap on this chuck until the jaws engage the threads on the body of the valve, the spindle of the machine is firmly held centrally in the opening. Next, the lower of the two hand wheels at the top of the spindle is turned so as to bring the cutter shown at the lower end of the spindle down against the valve seat. This cutter can now be rotated by turning the upper hand wheel by means of the crank, truing up the seat within the valve and making it as good as new. The stepped jaws of the centering chuck have a different pitch of thread on each step so that as the threads on the body of the valve become coarser as the valve is larger, the outer steps or shoulders having coarser threads are brought against the corresponding threads of a larger valve body. A flat cutter is shown in the engraving; of course, if the valve to be repaired has a taper seat, this cutter must be unscrewed and a suitable one put in its place.

If the valve disc is to be recut, the spindle shown in Fig. 1 is secured in a sort of lathe headstock, as shown in Fig. 2, and the valve disc, 3, is caught in a chuck on the end of the spindle as shown. The tailstock, 5, is moved along the guide, 4, so as to steady the valve disc for cutting. The cutting tool is secured in the end of the tool rest, 2, and is moved back and forth across the valve face as the valve is rotated by means of the crank. The tool rest is pivoted so that its angle may be changed to suit the angle of the valve disc. The whole machine may be conveniently held in a vise for this work. This machine will take nearly all the common sizes of work, but very large valves must be trued up in a lathe. It is best in doing this work to true up the valve seat first, and then take the angle of the cutter used for truing the seat to set the top slide of the tool rest for truing the disc. To test the accuracy of the work, it is well to make several chalk marks across the disc face and then put it on its seat and give it one or two turns; if the marks are obliterated their full lengths, it is certain proof that the disc face has been cut at the right angle.

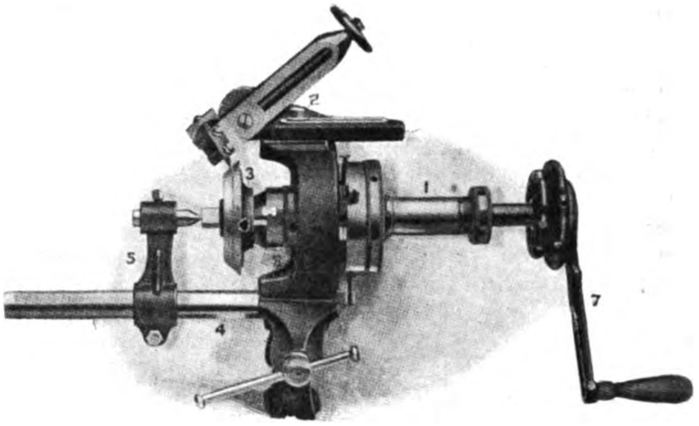

FIG. 2.—VALVE CUTTING ATTACHMENT.

A leaking plug cock is about the hardest to make tight of any valve with which an engineer has to deal. The extent of surface that must be ground away in order to work out a low spot in the plug or plug chamber is so great that ordinary grinding with oil and powdered glass is of no avail whatever. The only way to stop a leak in a plug cock caused by the metal being eaten away is to draw four lead pencil lines down the sides of the plug at about 90° apart, and then insert the plug in the chamber and give it two or three short turns back and forth; upon removal, the pencil lines will be obliterated on the high parts of the plug. The surface of the plug in the immediate vicinity of the obliterated lines should then be taken down with a fine file. When a good bearing is obtained all over the plug, a little grinding with glass and oil will usually make it hold. If it does not, the best thing to do is to get a new cock.

The next to claim attention should be the boilers themselves. All the doors and manhole plates should be removed, and the boilers thoroughly examined inside and out.

While on the inside of the boilers, particular attention should be paid to evidences of corrosion. This will be especially marked along the water line of the shell and along the line of the grate bars if internal furnaces are fitted. If the plates are at all corroded, they should be made perfectly clean and then painted with red lead and boiled linseed oil in order to prevent further corrosion.

Particular attention should be paid to what may be termed uniform corrosion to distinguish it from irregular wasting away or pitting. The writer has seen boilers in which the corrosion was so uniform and even and yet so extensive as to be positively dangerous, without having the appearance of being corroded at all. Perhaps no more striking illustrations of this could be found than the examples shown in Figs. 3 and 4.

In Fig. 3 is shown a section through the shell and steam dome of an ordinary tubular boiler, in which the corrosion was so uniform that the boiler was continued in use long after the danger line had been passed. The heads of the rivets holding the dome on the shell had been entirely eaten away, and the dome was actually taken off the boiler by driving the rivets back with a hammer. No other tool was used. The original thickness of the plate is shown by the dotted line around the inside. Fig. 4 shows another case in which the flat surface of a boiler was eaten away. The boss left under the inside nut was mistaken for a washer by the engineer, and this boiler was used under full head of steam until, in retubing it, the true state of affairs was revealed. The fact that uniform corrosion is very rare is at once a blessing and a curse; if it were more frequent it would be looked for more frequently and sooner detected, and if it were less frequent fewer lives would be lost.

When valves and the interior of the boilers have been carefully gone over and the furnaces have been inspected, the boilers should be closed with the exception of the upper manhole plates, which it is better to leave off until the boilers are filled to the steaming level. Water can be run into the boilers from the water main through the usual feed connections until it begins to show in the glass. At the first indication of water in the glass, the feed on that boiler should be stopped and a man sent into the boiler to measure the depth of water over the highest point of the heating surface. This measurement should be entered in a note book and carefully kept for future reference. After this the boiler may be filled to steaming level, which is usually about one-half the height of the glass, and the upper manhole plates put on.

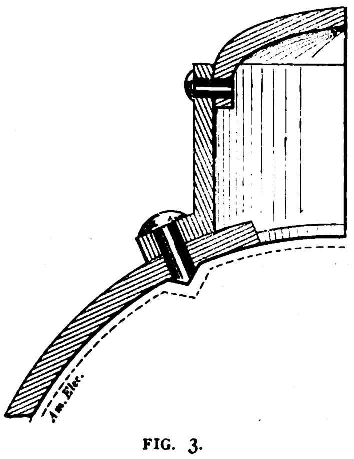

FIG. 3.

In preparing to light fires, it is usual first to cover the whole grate surface with coal and then put in wood. The object of first covering the grates with coal is to restrict the draft to the point in front where the fires are lighted. When the wood is well alight, more coal should be added. The fires should not be disturbed much if anthracite coal is used, as a hard coal fire will not stand much poking. With soft coal, the case is wholly different, and only a very little fire is needed to fully ignite the whole furnace charge. With this coal, as fast as it becomes thoroughly ignited in front, it should be pushed back so as to cause the entire charge to burn evenly through the furnace.

Steam should never be raised quickly on a boiler except under the most urgent circumstances. Nothing will make an old boiler out of a new one in less time than the practice of lighting fires, opening all the dampers, and "pushing her for all she is worth." Steam should not be allowed to form in less than from 3 to 12 hours, depending on the size of the boiler. (Steam may be generated in water-tube boilers in much less time; hence this remark only applies to shell boilers.) If the boiler has separate furnaces, fires should be first lighted in one of the outer furnaces, as this will cause the water to rise on that side and go down on the other so that circulation is very effectively established. There are several devices on the market for causing artificial circulation, and a better investment cannot be made than installing a good one.

Some feed pumps are connected to the bottom blow-off so that they may be used to empty a boiler, and where this arrangement exists, it is advisable to use the pump as a circulator to draw water out at the bottom and deliver it back into the boiler at another point; this being only possible, of course, when enough steam has been formed to run the pump. After the boiler has been thoroughly warmed up, fires may be lighted in the other furnaces. Where there is only one furnace, it is usually so arranged that the grate is beneath only the front part of the boiler shell, and the circulation is set up by the water rising in the front end, flowing back along the water line, and dropping at the rear where the heat is least.

While steam is being raised it is well to lift the safety valve in order to see that everything is clear and that it will operate. The practice of lifting the safety valve without steam in the boiler, which is followed by many, cannot be condemned too strongly. Sooner or later dirt or grit will be loosened so that it falls on the valve seat, and when the valve comes down on it, either the valve disc or the seat is scored, causing the valve to leak. By raising the valve when there is pressure on the boiler, any dirt that may be dislodged is at once blown out of the escape pipe. A drain should always be fitted to the lowest point of the escape pipe in order to prevent the pipe from filling with water, and thus causing an increase in the blowing off pressure because of the hydrostatic head of water pressing on the valve. It is also well to put a screen over the end of the pipe to keep birds from building their nests in it. The water column should also be tested before the steam pressure is high, to see that it is in working order.

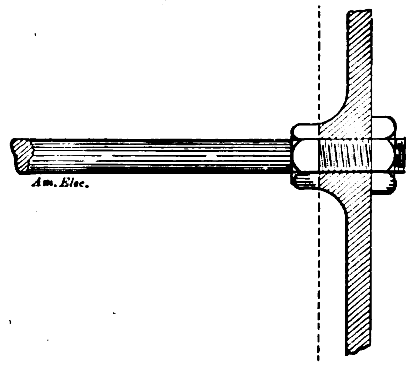

FIG. 4.

There are three systems of firing in general use; these may be termed the dead plate or coking system, the alternate system, and the spreading system. In the dead plate or coking system the coal is piled in the front of the furnace and there allowed to ignite from the fire underneath and back of it. This system is especially well adapted to bituminous coal, as the hydrocarbon gases that are distilled pass back directly over the fire and are burned; later the coke that is left on the dead plate is pushed back and a fresh charge is put on in front. This system would be almost useless with anthracite coal, as there are little or no hydrocarbon gases to drive off and burn, and it is also characteristic of hard coal that it must not be stirred if the best results are to be obtained. So pronounced is this latter characteristic that if an anthracite fire is stirred and has begun to die, it is best to haul it out completely and build a new one rather than try to nurse the old one back to life.

In the alternate system of firing, first one side and then the other is covered with fresh coal. This system always keeps one side uncovered so that the gases that are distilled from the fresh fuel are ignited and therefore do not pass up the stack unconsumed. It is equally well adapted to both hard and soft coal, and is deservedly popular with engineers. This system undoubtedly has the disadvantage of requiring more skill in firing than does the dead plate system, as it is not easy to spread a shovelful of coal evenly over a large area.

The spreading system is where the coal is spread evenly over the entire surface. This method requires that but little coal shall be put on at a time, as a heavy charge would lower the temperature of the furnace and cause a loss of fuel through the formation of carbon monoxide. It is usually used when firing the smaller sizes of anthracite.

The desirable thickness of a bed of burning fuel is one on which there is considerable difference of opinion. Some engineers prefer a thick bed of fuel because such a fire is less sensitive to changing conditions, and is not so apt to burn through in spots and allow cold air to rush into the furnace and chill the boiler plates. On the other hand, a thick fire retards the draft and is more apt to cause a loss of fuel through imperfect combustion. It is also evident that the doors must be opened oftener when fires are kept thin. It is probable that the best results will be obtained when a compromise is effected between these conflicting conditions and a medium thickness of fire is maintained. Where several furnaces discharge into one stack it is of the utmost importance that the fires be kept of the same thickness; otherwise the thin fires will burn out first because they get most of the draft. It is an old trick of the lazy fireman, where there are several on a watch, to keep thicker fires than his neighbors, as he does not have to handle as much coal. Moreover, he gets the reputation of being a very economical man, as there is less coal delivered to him than to the others.

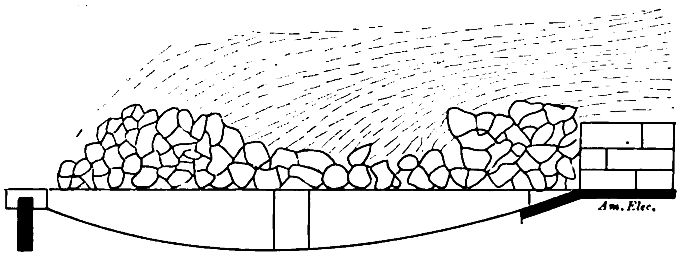

FIG. 5.

The evils of uneven firing are fairly well indicated by Fig. 5. Here is shown a thick bed of fuel in front, a thin bed in the middle, and back against the bridge wall it becomes thick again. The natural result of such firing is that the fire burns through in the thin places, because the draft is very much greater here than elsewhere, while the points at which the fires are thick do not get sufficient air for complete combustion, thus producing a waste of fuel. When the fireman replenishes the fires it is more than probable that the hollows are filled up with green coal which, as it has no burning fuel beneath, does not readily ignite. Combustion will now be fiercest where the thick places were before coaling, and these soon burn out, making thin spots, and the whole wasteful operation is repeated. No truer sign of a good fireman is to be found than an even fire.

It should be the aim of a fireman to maintain the steam pressure as near constant as possible. The direct effect on the boiler of a varying pressure is ruinous, as the varying pressure means a varying temperature, with its attendant expansion and contraction of the boiler. Another advantage of maintaining a uniform pressure is an indirect one. If the pressure is constant, it means that the furnace temperature has been maintained without much fluctuation, and this always is conducive of economy of fuel. A uniform water level means vigilant care and may generally be said to be characteristic of good fireroom management.

When shutting down for the night it is necessary to preserve the fires in some way and yet prevent them from developing enough heat to raise the steam pressure. This object is accomplished by banking the fires. A fire to be banked is first allowed to burn down fairly well, and then it is all pushed back against the bridge, leaving the front of the grate bare, or it is all pulled forward, leaving the back of the grate bare, and then covered heavily with fresh coal. When the fire is pushed back it tends to choke the passage over the bridge, and as all the air that passes through the boiler must pass over the fire, it is quite hot. As there is sufficient heat present in this hot air to more than maintain the steam pressure, it is more usual to bank in front and allow cold air to pass through the back of the grate and up the stack. This latter method is more injurious to the boiler than the former, but as it is more effective in keeping down steam it is much oftener used.

Before leaving the boilers they should be pumped up until every glass gauge is nearly or quite full of water, so that the morning engineer will have a chance to use the bottom blow-off without bringing the water below the steaming level. It is in the morning before the fires are spread that the sediment and dirt in the water is most apt to be on the bottom; hence the morning is the best time for blowing down.

In conclusion, attention should be called to the fact that an employer is very apt to judge his engineer and fireman by the general appearance of the steam plant. The extra labor involved in keeping brass work bright, floors swept, and boiler fronts painted with boiler paint is small, and no engineer who is mindful of his own best interests will neglect these points.

HINTS ON HANDLING BOILERS.

Can a boiler be forced as hard when fired by automatic stokers as when fired by hand? In the N. E. L. A. *Question Box* this inquiry is answered both in the affirmative and in the negative. The "average" of the opinions, however, appears to be that if the stoker is adapted to the grade of coal being burned, and is a first-class apparatus, the boiler can be forced about as hard as with hand firing. No sweeping reply to the question can possibly be correct, for the reason that the conditions of operation have everything to do with the problem. Probably the reply of Mr. W. L. Abbott, of the Chicago Edison Company, fits the case as well as anything short of an analytical discussion could; he expresses the opinion that with the same draft conditions a boiler can be forced harder when fired by hand than when automatically fired, unless the stokers are arranged so that the fires can be readily raked and stirred.

Concerning the cleaning of a water tube boiler, the majority of the opinions expressed in the *Question Box* are to the effect that the hand-hole covers in the rear section should be removed while cleaning, so that the worker can *see* whether or not the cleaning is thorough; it is not at all safe to rely upon the blow-off to complete the job. Practically all of the covers in the front heads of a water tube boiler should be removed for cleaning out, and the hand-hole covers should all be marked for identification so that they can be put back exactly as they were before removal. Of course, when new gaskets are to be put in, this is not strictly essential.

THE ADVANTAGES OF CONDENSING.

It is one of the more recent dogmas that there is but little if any advantage in using condensing engines when high boiler pressure is available. This fallacy has obtained quite a considerable sway of late years, especially in regard to electrical working. When boiler pressures were only 20 to 30 pounds, it is evident that even without any expansion whatever, an additional 15 pounds due to condensing was a very substantial addition to the mean pressure available from an initial pressure in the boiler for the above small amounts. With boiler pressures of 150 pounds, a superficial thinker may, perhaps, look upon an extra 15 pounds as too trivial to take into account. Let the actual facts of practice be considered, however. A modern engine too frequently has the fault that it does not get anything like full boiler pressure upon the piston unless at full load.

An ordinary compound engine at 75 per cent. of its normal load will show a mean pressure referred to the low-pressure cylinder of perhaps 30 pounds. If the engine is of small size, it will be running on an average load of not more than half the normal rating, with a mean cylinder pressure of about 20 pounds. Under circumstances of this kind the power given by condensing working is relatively very large, and it cannot be urged with any show of reason that a traction load can be run economically by a non-condensing engine. The error has arisen, in all probability, as the outcome of earlier days of electrical working, when only lighting was undertaken. The maximum peak of a lighting load is of very short duration, and it can be got over by running a cheap and uneconomical engine for a very small part of the time. In such a case a certain amount of reason can be advanced against the use of expensive plant to get over a peak of short duration. But a traction load bears no resemblance whatever to a lighting load. Its peaks occur every few minutes or every few seconds. It is impossible to put on and take off an engine to suit the momentary fluctuations. The same engine must run, at one moment carrying a load of 150 per cent of normal, the next carrying but 30 per cent of normal.

Without a battery to equalize the load

on the engine, it is simply out of the question to expect economy from an engine so loaded, but there is no reason whatever for employing a larger non-condensing engine, when one of two-thirds the size, or even less, will turn the same load when condensing.

The economical load of a factory engine asks for 40 or 45 pounds mean cylinder pressure. When only 25 or 30 pounds can be secured it is impossible to have economy, not only because the engine frictional loss is great in proportion to the useful load, but because all other losses are increased, notably, those due to cylinder condensation.

The effect of a battery and reversible booster is to enable an engine to run at a higher mean cylinder pressure, for the necessity is abolished of coping with maximum load peaks by the unaided engine. Without a battery the one engine has to be aided by a second engine. The economy of a battery comes in the abolition of the second engine, with its duplication of losses. There is no economy to compare with condensing when applied to a traction plant, unless it be the battery which equalizes the engine load. Unfortunately, it is only too common to find the benefits of condensation thrown away to a very considerable extent. —London *Electrical Review.*

THE THREE-WIRE GENERATOR.

The three-wire generator is a direct-current dynamo giving the full over-all voltage at the brushes and having a third terminal, which is connected to the neutral of the three-wire system. This third terminal is connected to the middle point of an auto-transformer or "balancing" coil, the terminals of which are connected to points of opposite potential in the armature winding of the generator. The function of the auto-transformer may be better grasped perhaps by considering the elementary properties of such a device.

If a coil of wire, wound on an iron core, such as is used in transformer construction, be connected to an alternating-current circuit of 100 volts potential, and a tap be led out from the middle of the coil, as indicated in Fig. 1, a voltmeter applied to the wires *a* and *b* will, of course, indicate 100, and if it be connected to the wires *a* and *n*, or to *b* and *n*, it will indicate 50 volts, or one-half of the over-all voltage. The reason will be clear upon a little consideration. The impedance of the two parts of the coil on each side of the neutral or center tap is exactly the same; consequently, the impedance "drop" in each half is the same, and the sum of the two "drops" is equal to the over-all e.m.f. If the tap were connected in at a point one-third the way from one terminal of the coil, the e.m.f. between the tap and the nearest terminal would be one-third of the over-all e.m.f., and so on, for any other division of the winding.

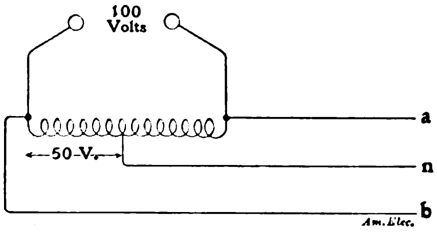

FIG. 1.

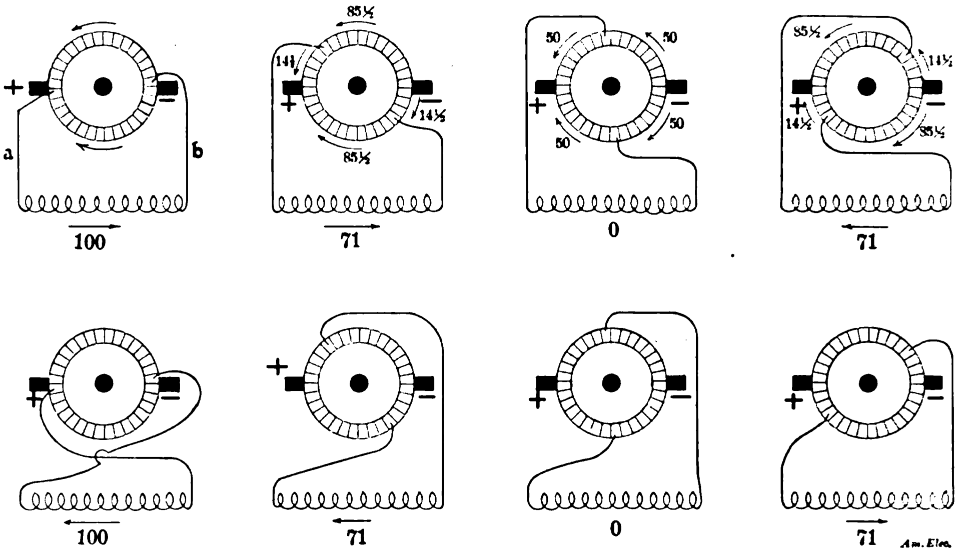

FIGS. 2 TO 9.

If a load, such as a group of lamps, be connected between the wires *a* and *n*, the voltage between those wires will drop slightly below 50, because the additional current flowing through the lamps will increase the "drop" in the right-hand half of the winding. The drop will not be as great as one would think, however, because the additional current flowing through the *left-hand* half of the coil will induce an e.m.f. in the right-hand half, which tends to compensate for the drop in that half of the winding. Therefore, if groups of lamps be connected on both sides of the neutral, the voltage between the neutral and each outer wire will be maintained almost equal even if the groups are not alike in current requirements.

The balancing coil of a three-wire generator acts exactly like the auto-transformer. It receives alternating current from the armature winding, as consideration of Figs. 2 to 9 will show. The diagrams show the connections for a bipolar machine, for simplicity; one terminal of the balancing coil connected to one point of the armature winding and the other terminal to the opposite point. If the e.m.f. at the brushes is 100 volts, this e.m.f. is applied to the coil when the armature coils to which it is connected are in immediate connection with the brushes by means of the commutator, as in Fig. 2. When the armature has turned through one-eighth of a revolution, the e.m.f. at the terminals of the balancing coil will have dropped to about 71 volts, as indicated in Fig. 3, because the e.m.f. induced in that part of the armature winding between the positive brush and the left-hand tap neutralizes an equal part of the e.m.f. induced in that part of the winding between the negative brush and the same tap. The arrows and numbers indicate the various e.m.f's. At one-fourth of a revolution, the e.m.f. at the balancing coil terminals has dropped to zero, as indicated in Fig. 4. Then, as the armature proceeds, the e.m.f. begins to rise in the opposite direction, and at one-half revolution (Fig. 6) it is 100 volts again, but opposite to its original direction. These eight diagrams show the complete cycle.

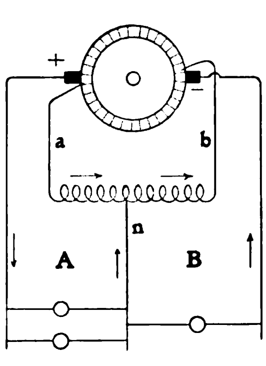

FIG. 10.

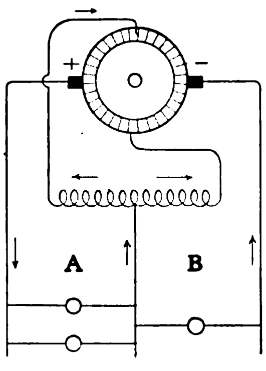

FIG. 11.

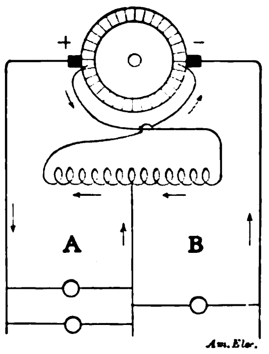

FIG. 12.

Figs. 10, 11 and 12 show the relations with an unbalanced load for the three principal positions of the armature. The current for the two lamps in the *A* side goes from the dynamo brush out over the positive wire, and through the two lamps; at the neutral wire it splits, half going through the *B* lamp and back over the negative wire. The other half, required for the second lamp on the *A* side, goes back over the neutral wire, *n*, and combines with the current in the right-hand half of the balancing coil, returning thus to the armature coil at the negative brush. In Fig. 11 there is no e.m.f. at the terminals of the balancing coil, so that the return current from the neutral wire, *n*, divides and passes through both halves of the coil to the armature winding. In Fig. 12 the conditions are exactly opposite to those in Fig. 10; the current from the neutral wire returns to the armature winding through the left-hand half of the balancing coil. It will, or should, be obvious from these three diagrams why the current in the balancing coil is alternating, while that delivered from the neutral wire to the coil is direct; the neutral current simply enters the balancing coil at the middle and passes through first one half and then the other, according to the directive effect of the e.m.f. applied to the coil by the armature winding.

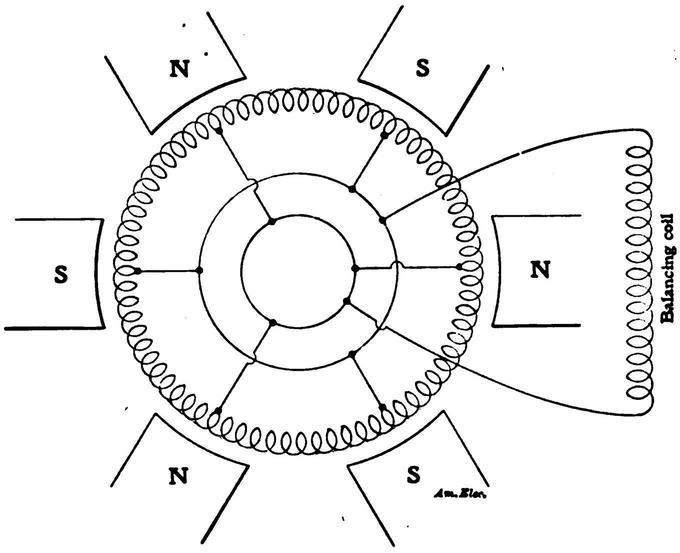

FIG. 13.

In practice, three-wire machines are multipolar, but this does not affect the functions of the balancing coil; one of its terminals is connected to all of the points in the armature winding that are of equal potential at any given instant and the other terminal is connected to all the points that are at equal but opposite potential at that same instant. Fig. 13 illustrates this diagrammatically.

The balancing coil may be mounted on the armature spider, with its terminal connected directly into the armature winding and its middle point connected to the neutral wire through a slip ring and brush, or it may be stationary, with its middle point connected solidly to the neutral and its terminals connected to brushes which bear on slip rings connected to the armature winding like those of an ordinary alternator. It is usually preferred to mount the coil on the armature structure; this reduces the number of slip rings to one and provides very effective ventilation of the coil by fanning. It is also the practice to use two or more balancing coils connected to equidistant points in the armature winding in order to smooth out the fluctuations in the neutral circuit.

Electric Railway for Mont Blanc.—M. Baloit has prepared plans for an electric railway to be built up Mont Blanc. The cog-wheel system will be employed. In the ascent of 11,710 feet the road will traverse eleven miles.

ALTERNATING-CURRENT SUB-STATION OPERATION.

BY S. L. PEARCE.

There are three possible ways of starting up a rotary converter. (1) From the alternating current side by switching it straight on to the supply lines. This method was adopted, and as far as the author knows, is still in vogue on the Central London Railway system, and on the Liverpool and Southport line, in the case of the first rotary to be started up each day. It is necessary to have a field-splitting switch in order that the shunt winding may be opened before starting, otherwise they would break down owing to the excessive e.m.f. induced at the moment of closing the alternating main switch. Further, if the rotary be compound wound, the series field windings must be open-circuited. All switches on the direct-current side must be left open before switching the rotary on to the line. By reason of the hysteresis lag in the pole faces, and in a lesser degree due to the eddy currents set up, the rotary will start as soon as the alternating-current switch is closed, and will immediately run up to synchronous speed. As soon as synchronism is attained, the field-splitting switch and direct-current field switch can be closed. With self-exciting sets care must be taken to see that the latter is closed as the machine is building up on the right polarity, which can be done by closely observing the direct-current voltmeter. If this is not done, the polarity on the direct-current side of the rotary will be reversed.

The rotary will now be running in synchronism with the main generators, and can be paralleled on the low tension bus-bars in the usual way. Although this method may be unavoidable in some cases, it has serious disadvantages, chiefly on account of the large current at low power-factor which it draws from the supply lines, and the possibility of the rotary building up on the wrong polarity. For traction work this method may be employed, but not for lighting purposes.

(2) Starting up from the direct-current side. This is a far simpler operation, presents no difficulties of operation, and can usually be followed in most instances where a supply of direct current in the sub-station is available. In the case of the Central London Railway this method was always adopted for all sets after the first. For lighting systems the starting current required for large units might occasion a heavy drop on the distributing mains, and it will become necessary either to provide an induction motor generator set to supply the necessary direct current, or, better still, the third method may be usefully employed.

(3) This consists in coupling on to an extension of the rotary shaft a small, three-phase, low-pressure induction motor, the capacity of which should be approximately one-tenth of the full load output of the rotary. By means of this starting motor, the whole set may be brought up to synchronous speed, the alternating-current and direct-current fields adjusted, and then synchronising the alternating current side of the rotary on to the line, afterward cutting out the starting auxiliary unit.

The starting up of synchronous motor sets presents no difficulties, and is usually done from the direct-current bus-bars, synchronising on the alternating current side in the usual manner. It is, however, absolutely necessary that provision be made in every sub-station for the plant to be started up from the alternating-current side in the event of a possible shut-down of the lighting or traction systems. Such means are to hand in the employment of induction motor sets, which in lighting sub-stations are frequently coupled up to the balancers. Their value in this respect forms good reason why a combination of induction and synchronous motor sets is desirable. If battery power is available, this will provide the alternating direct-current supply, but it rarely happens that battery stations and polyphase sub-stations are combined.

A method of starting up applicable to both rotaries and synchronous motor generators is shown in the accompanying diagram, and is a slight modification of the first method described for the starting up of the former. The compensator reduces the primary voltage to one-half, the double throw oil switch, which is fitted with an over-load device, being thrown down to the bottom contacts. Half voltage is thus impressed on the rotary, or synchronous motor, and the field switch being left open, the machine runs up on an induced field. When full speed is attained, and the field built up in the right direction, the field switch is closed, the oil switch is thrown over on to the top contact, i. e., on to the full voltage bars, and the starting high tension oil switch is withdrawn.

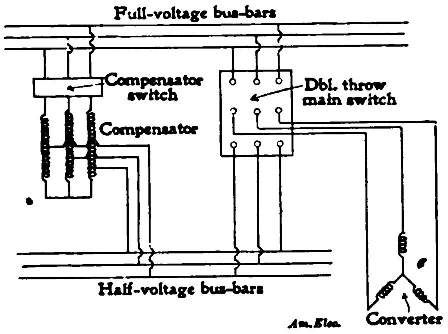

FIG. 1.

The motor generator with induction motor is the simplest of all types of sub-station equipment to start up. With long feeders it is desirable that the pressure on the feeders should be applied gradually to the stator of the induction motor, as any throw-up in the voltage due to the capacity of the feeder at the moment of switching on might break down the insulation of the motor. A suitable design of three-phase stator starter to be used for the purpose consists of three coils arranged in a triangle, and carefully insulated by cylinders of mica. Each coil is provided with an adjustable core consisting of a large number of iron sheets 1/50-in. thick. The three iron cores are attached to a round disc, which is held by a three-armed cast-iron holder, through the middle of which runs a screw, and the three iron cores can thereby be raised and lowered. The three coils are switched in series with the corresponding phases of the motor which is to be started up.

Before switching in, the iron cores are lowered into the coils so that on first switching in only a small current goes into the stator of the motor. The cores are then gradually raised out of the coils, the inductive resistance being thereby gradually lessened, and finally the coils are short circuited. A water resistance or other suitable form of starter is inserted between the slip-rings of the rotor, and short-circuited as soon as the set is up to speed, when the machine can be paralleled in the usual manner on the direct current side.

On account of the heavy rotor cables with large units, it is desirable, to avoid expense, that the rotor starter should be placed as near the machine as possible, and a convenient arrangement is to operate it by means of bevel gearing from the front of the switchboard platform.

Rotaries are invariably self-excited for obvious reasons. There is one strong disadvantage, however, with this method, consequent on the possibility of the rotary reversing while under load. This happened on two or three occasions on the Central London Railway system, and is a possibility to be reckoned with. If the rotaries are excited from the bus-bars, then a battery connected across the bars becomes imperative.

For synchronous sets employed on traction circuits, a separate exciter mounted on the end of the shaft is probably the best method of exciting the high tension motor fields. Although it occupies extra space, it provides an alternative method of excitation from the lighting bus-bars where a mixed system is supplied. In any case it is desirable that the excitation for the traction sets should be independent of the lighting system, and this can best be obtained by the use of a separate exciter, or by a method described later on. For synchronous sets on lighting networks, excitation from the direct-current terminals or low-tension bus-bars will probably be found sufficient. The author considers that the question of excitation is of importance, and should be well considered.

The effective balancing of a three-wire lighting network from sub-stations can be secured by the use of an induction motor coupled to two generators giving about half the pressure across the outers, the whole combination forming an auxiliary set for the supply of direct current necessary to start the larger synchronous units.

It is, however, desirable that additional means of balancing should be provided, either by the use of double-wound armatures with the synchronous sets or other methods. An alternative arrangement has been used extensively in the Manchester sub-stations, and emanates from the Allgemeine Electricitäts Gesellschaft. This apparatus is essentially a choking coil, the ends of which are connected up by means of two slip-rings to the armature of the direct-current dynamo. The slip-rings are connected up to the armature at such points that a normal alternating current at the frequency corresponding to the number of pole-pieces and the revolutions is circulating in the equalizer. The middle wire of the system is connected up to the middle point of the choking coil. If the load on each of the two net-halves is unequal, the over-load on one will pass through the middle wire into the respective side of the equalizer, and through the slip-ring belonging to it back into the armature. This method also provides another supply for exciting current, and if all the synchronous plant in each sub-station is so arranged, it is evident that each set will be self-excited. An out of balance current up to 25 per cent can be dealt with under this arrangement without the difference in voltage exceeding 2½ per cent of the mean voltage.

[The foregoing is part of a paper on "Polyphase Sub-stations," read before the ninth annual convention of the Incorporated Municipal Electrical Association, at Derby, Eng.—EDITOR.]

Lessons in Practical Electricity

TESTING FOR TRANSFORMER LOSSES.

The amount of power absorbed by the core losses in a transformer may be determined with sufficient accuracy by connecting the secondary terminals of the transformer to a circuit of the same voltage as that of the transformer secondary and of the frequency for which the transformer was designed, leaving the primary terminals free and including a wattmeter in the secondary circuit, as shown by Fig. 1. The wattmeter will then indicate approximately the power absorbed by core losses. The object in connecting the transformer up at the secondary end instead of at the primary is to enable one to use an ordinary wattmeter without interposing a transformer between the wattmeter and the circuit. The test could be just as well made on the primary of the transformer if the wattmeter could be connected to the primary circuit. While this test is sufficient for all practical purposes, it is not absolutely accurate, because there is a very small copper loss during the test due to the passage of the exciting current through the secondary winding. This is practically negligible, however, and a test made in this manner answers all ordinary requirements.

The foregoing test, as stated, shows practically the amount of power required to supply the core losses in the transformer, which comprise the loss due to hysteresis and that due to eddy currents. It is not practicable by any convenient method to separate these two losses; moreover, the separation of these two losses is not of any practical importance to the user of the transformer. Should it be desirable for purely experimental purposes to ascertain which of the two losses preponderates this can be done by connecting a voltmeter across the secondary terminals of the transformer, inserting an adjustable resistance in the circuit beyond the wattmeter, and adjusting this resistance until the e.m.f. at the secondary terminals is one-half of the normal value. If all of the core loss were due to hysteresis the wattmeter would indicate practically one-third of the loss that is indicated when the voltage was normal. If all of the core loss were due to eddy currents the wattmeter would indicate only one-fourth of the power indicated when the voltage was normal. If its actual indication, therefore, is nearer one-fourth than one-third of the power indicated with the voltage normal, the eddy-current loss preponderates; and if it is nearer one-third than one-fourth, the loss due to hysteresis is greater than that due to eddy currents.

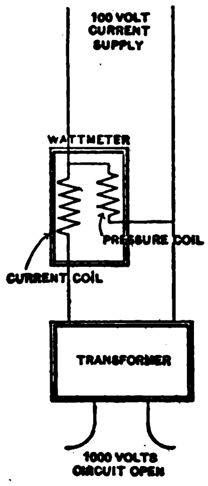

FIG. 1.—CORE LOSS TEST.

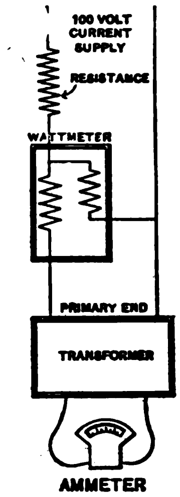

FIG. 2.—COPPER LOSS TEST.

In order to test for copper losses the most accurate method is to connect the primary winding of the transformer in series with an ammeter and an adjustable resistance across a low-potential, direct-current circuit and vary the resistance until the current passed is equal to the full-load primary current of the transformer; then measure the difference of potential at the terminals of the primary winding and multiply this by the current flowing; the result is the copper loss in the primary. Make a similar test of the secondary and add the two results together to obtain the total full-load copper loss.

Another method, which is more convenient but not quite so accurate, consists in short-circuiting the secondary of the transformer through an ammeter, connecting the primary in series with an adjustable resistance across a low-voltage alternating-current circuit of the proper frequency and also connecting a wattmeter in the primary circuit, as indicated by Fig. 2; the resistance is varied until the normal full-load secondary current is indicated by the ammeter, when the wattmeter will indicate approximately the power absorbed by the windings of the transformer. As just intimated, the result of this test will not be absolutely accurate, for the reason that some of the energy supplied by the test circuit is absorbed by iron losses; these, however, are extremely small on account of the low voltage at the terminals of the primary winding.

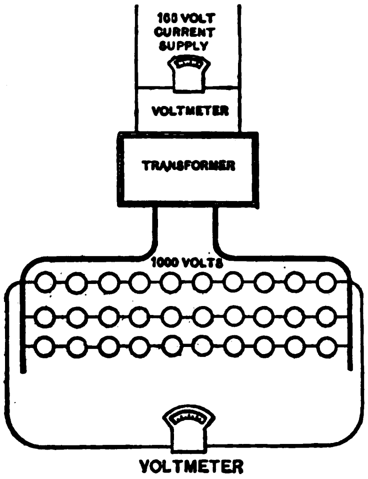

FIG. 3.—TESTING FOR FULL LOAD DROP IN VOLTAGE.

As has been explained in previous Lessons, the eddy-current loss varies as the square of the magnetic density in the core, and the hysteresis loss varies as the 1.6 power of the density; as the density is practically proportional to the impressed e.m.f., the eddy-current and hysteresis losses may be considered to vary respectively as the square and the 1.6 power of the e.m.f. It is evident, too, that at the low e.m.f. necessary to load a transformer short-circuited as shown in Fig. 2, the core loss will be almost negligible. However, should one desire to refine the test a more accurate result may be obtained as follows: Make an initial test as just described and call the result the gross loss; then disconnect the secondary terminals from the ammeter, adjust the e.m.f. at the primary terminals to be exactly the same that it was during the first test; test the core losses as described in the beginning of this Lesson; subtract this result from the first one, and what remains will be the actual full-load loss in the windings.

To test a transformer for drop in secondary pressure it is only necessary to connect the secondary to a supply circuit of the proper voltage, and measure the e.m.f. at the primary terminals with the primary circuit open. Then load the primary circuit with lamps, as shown in Fig. 3 and adjust the voltage at the terminals of the secondary until it is exactly the same as before, and again measure the e.m.f. at the primary terminals. The difference between the two readings of the primary voltmeter divided by the ratio of transformation will give the drop which the transformer will show at the secondary terminals when used in the ordinary manner and supplied with constant e.m.f. at the primary terminals. The object in making this test in the manner described instead of supplying the transformer from a primary circuit and loading the secondary is to avoid as far as possible manipulating the primary circuit. The test as described only requires one to close a switch in order to throw the lamps on the primary terminals, whereas, if the transformer were tested in the reverse manner the e.m.f. at the primary terminals would have to be adjusted by means of a rheostat, which might cause accidental personal contact with the primary circuit and result seriously.

The method of testing transformer losses with which most station men are familiar consists of simply connecting the transformer up to a primary circuit and measuring the current which passes in the primary when the secondary is open. Such a test is entirely worthless in arriving at the core losses, as the current is out of phase with the primary e.m.f., and consequently, multiplying this current by the primary e.m.f. does not give the actual watts absorbed by the core losses. The simple substitution of a wattmeter, as indicated in Fig. 1, in place of a voltmeter and ammeter changes this test from one which means nothing into one which is sufficiently accurate for all practical purposes in central station work.

Mr. Clark's Potential Wire Effect.

To the Editor American Electrician:

Referring to Mr. Clark's communication in the July number, on "An Unusual Potential Wire Effect," I beg leave to submit the following explanation: It was pointed out by Mr. John W. Howell, some years ago, that a current which will produce a drop of one volt in the neutral wire of a three-wire system (in which all three wires are of the same resistance) will produce an unbalancing of three volts; or in general, the unbalancing of voltage will be three times the drop in the neutral. A general proof of this statement might be given, but for the present purpose we may consider several numerical examples.

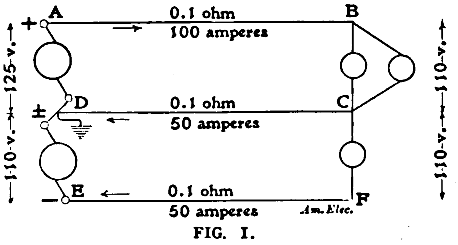

FIG. 1.

Fig. 1 shows two dynamos connected to a three-wire system, the load being unbalanced as shown. For convenience in finding the difference of potential between various points, it will be assumed that the neutral wire is grounded at the bus-bar, as shown, and that the potential of the point, *D*, is, therefore, zero. It is to be noted that this is done only for convenience, and that the result in no way depends upon the fact of this point being grounded. The voltage of each machine being held such that the pressure is 110 volts on each side at the feeder end, we may find the potentials of the points *A* and *E*, as follows: Current flows from *C* to *D*; hence *C* is at higher potential than *D* by an amount equal to the drop in the neutral, or the potential of *C* is + 5. The potential of *B* is 110 volts higher than that of *C*, or + 115; and in like manner the potential of the point *A* is found to be + 125. The potential at the point *F* is 110 volts below + 5, or is — 105; the potential at *E* is 5 volts lower, or — 110. The dynamo on the negative side is, therefore, operated at 110 volts, and the one on the positive side at 125 volts. The unbalancing of voltage is 15 volts, or three times the drop in the neutral.

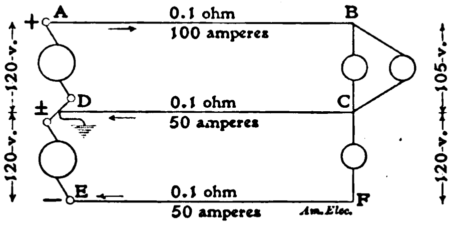

FIG. 2.

Next, assume that the pressure is kept at 120 volts on each machine at the bus-bars, as in Fig. 2. By the same method as in the preceding case we will find the voltage on the positive side at the feeder end to be 105, and that on the negative side to be 120, giving the same unbalancing of voltage, namely, 15 volts, which is three times the drop in the neutral.

In both of these cases the unbalanced load is such that the pressure on the lamps on the negative side is the same as the pressure between the negative and neutral bus-bars. If the load is still more unbalanced, or if the neutral wire is made smaller, we will have the condition Mr. Clark mentions. This condition is illustrated in Fig. 3. In this case the load is assumed to be 150 amperes on the positive side, while the negative side carries 50 amperes, as before. By the method above used we will find that if the pressure is to be kept at 110 volts on each side at the feeder end, the dynamo on the positive side must be operated at 135 volts, and the one on the negative side at 105 volts. The drop in the neutral wire is now 10 volts, and the unbalancing of voltage is 30 volts, or three times this drop, as in the other cases. The pressure between the neutral and the negative bus-bars is now 5 volts *less* than the pressure on this side of the system at the feeder end.

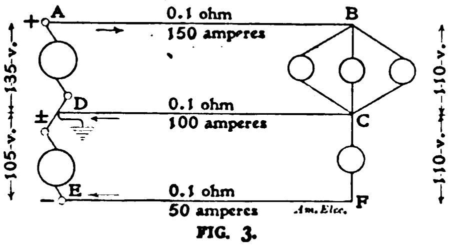

FIG. 3.

In the foregoing examples I have considered the neutral wire to be of the same size as the outside wires. If, as is often done, the neutral wire be made smaller than the outside wires, a given drop in the neutral will be produced with a smaller current, and the effect Mr. Clark mentions will be produced before the unbalancing of the load becomes as great as in the cases considered.

Washington, D. C. H. B. BROOKS.

To the Editor, American Electrician:

The peculiar condition of a three-wire system in which the potential at the center of distribution is actually higher than that of the bus-bars or dynamo on the same side of the system, as described by Mr. H. Lee Clark in the July number, may exist when such a system is considerably unbalanced. As an explanation of this discrepancy in voltage, I offer the following in connection with the potential diagram, Fig. 5, corresponding to the arrangement of apparatus shown in Fig. 4, where *B* and *D* are 125-volt dynamos supplying 400 amperes to a group of lamps on the positive side of the system and 100 amperes to a group on the negative side.

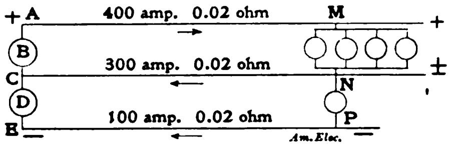

FIG. 4.

Assuming the neutral to be the same size as the main conductors and that the resistance of each of the three wires is 0.02 ohm, the drop of potential on the positive main (between *A* and *M*) will be 8 volts for a current of 400 amperes. The drop on the neutral wire between *C* and *N* will be 6 volts, since 300 amperes must return to the positive dynamo through it. Then a potential of 125 volts at each dynamo will give 111 volts between *M* and *N*. On the negative wire the drop between *P* and *E* is 2 volts; therefore, the potential at *P* is 2 volts higher than that at *E;* but as the potential at *N* is 6 volts above that of *C*, it is evident that the voltage between *N* and *P* is 4 volts greater than that between *C* and *E*, due to the dynamo *D*.

Such a condition is not likely to occur in practice, especially in a large system, where the load is carefully balanced. In case the neutral wire is only one-half as large as the outside wires, which is actually the case in many systems, the discrepancy in voltage would be much larger.

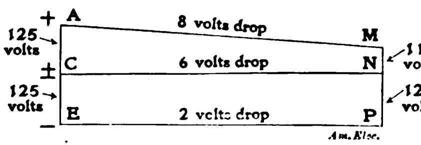

FIG. 5.

Los Angeles, Cal. GEO. A. SCHNEIDER.

[Both of the foregoing letters were received several days before the August number was issued, but too late for insertion in that number.—EDITOR.]

Flashing Over by Rotary Converters.

To the Editor, American Electrician:

Regarding Mr. Jerome's trouble with his rotary converters, the writer is of the opinion that he is operating the machine with the brushes not on the proper point for commutation. The running position is slightly in advance of the no-load neutral point on the commutator and it should be brought as far forward as possible without causing undue sparking. Sometimes it will be found necessary to make the machine spark slightly at the no-load neutral point in order that it may carry its maximum overload satisfactorily. Mr. Jerome should satisfy himself that the brushes are set equidistant apart about the commutator. The writer has found pole pieces spaced accurately mechanically, but not equal magnetically; in such cases the brush-holder stubs should be moved so that the e.m.f. generated between adjacent brush-holder stubs is equal. His trouble may also be due to the fact that he is operating more than one rotary on the same transformer secondary, which will cause undue current to be exchanged between the machines. If the rotaries can be separately excited a more stable field can be obtained than with self-excitation, since the alternating-current voltage fluctuates on the alternating-current side of the rotaries. This will in most cases overcome all flashing over evils. I have cured several 60-cycle rotaries of bucking and flashing over by cutting with a hacksaw a very narrow slit in the carbon brushes parallel to the commutator bars about ⅜ in. deep. This does not reduce the conductivity of the brush, but enormously increases the contact resistance to the short-circuiting currents flowing under the brushes. I have also found that this increases the life of the commutator very materially and does not require the sandpapering of the commutator so often. The brushes should not be shifted too far forward, as the circuit-breaker will open as the load increases and cause the machine to spark badly at this point if overreached. Sparking is also liable to occur when the prime mover or generator momentarily increases its speed, causing a difference in phase between the generator and converters. The difference in the instantaneous e.m.f. due to the difference in phase causes a corrective current to flow in the circuit, which will distort the fields and accelerate the converter armatures, thus placing the commutator coil in a strong field and producing flashing and bucking.

San Francisco, Cal. F. P. DE WILDE.

To the Editor, American Electrician:

Referring to Mr. Jerome's trouble with rotary converters, I would suggest that the flashing over is caused by the improper position of the brushes, the flashing being due to short-circuited coils. I think if he will shift his brushes the flashing will cease

Ladonia, Tex. WILSON A. McCOWN.

To the Editor, American Electrician:

The trouble described by Mr. Jerome in the August number of the AMERICAN ELECTRICIAN is probably due to improper brush contact. I would suggest that the commutator be examined, and if it is in good condition the only remedy is to shift the quadrant so as to cause the brushes to make better contact.

Newark, N. J. JAMES J. FOX.

Fires from Electrical Causes.

To the Editor, American Electrician:

The attention of AMERICAN ELECTRICIAN readers has doubtless been attracted by the great fires of the past year in American and Canadian cities, in which much of the blame was at once laid on electric wires. Every one knows that the Fire Underwriters' regulations call for work and material calculated to make the installations safe to the extreme, and this work is done under the strict supervision of the underwriters' inspectors. No one would think of a fire being started by wiring done under such circumstances. The writer has, however, made note of several fires which have been caught before they reached any magnitude, and in 15 years' experience has yet to see the first fire caused by the wires themselves. The causes of the fires mentioned below were the fault of the apparatus used and not the wires.

In a Pennsylvania town there was a first-class job in house wiring done by a responsible Philadelphia firm. The primary and secondary wires of the transformer accidently crossed on the pole in the street, by which the 2000-volt primary circuit was connected with the house wiring. The result was that all the lamps in the house blew to pieces, and a fierce arcing took place at the fuse blocks, which fired the cupboard in which they were placed.

Another fire was caused by an elevator motor controller; a shunt motor was used, and we all are aware what current a shunt motor takes when starting under load and the field cannot reach its full strength immediately. The operator stopped the car about a couple of inches from the proper level, and this is where the mischief commenced. He wanted to move two inches, so he pulled the switch rope and then threw it off immediately. The switch drew a long arc, which was maintained at the contacts. The motor could not run, owing to the brake being on the machine. The controller burned up, setting fire to surrounding woodwork. In still another case an alternating-current motor controller had a broken coil in its rheostat, and this wire came in contact with the iron case. The controller was operated mechanically by a wire cable and the machinery was thus charged from this faulty rheostat. The lifting cables passed through the ceiling of the top floor of the building, which was covered with ornamental iron ceiling, and when the lifting cable made contact with this tin, arcing commenced, resulting in the burning of the ceiling. We are required to put circular loam over our wires and tack asbestos over everything in order to make it safe, while these other incidents are occurring daily, and there is no enforced protection.

New York. B. THOMAS.

Queries and Answers

IMPORTANT.—No attention will be given to any inquiry which does not give the full name and address of the inquirer.

Is there any practical method of testing rolled steel or iron shafts by electricity to locate flaws?
W. F. R.

We do not know of any.

What causes a shunt-wound rotary converter to spark at the direct-current brushes when being started up on the alternating-current side?
H. R. B.

The breaking of the short-circuit on armature coils carrying heavy induced currents as the commutator segments pass from under the brushes.

What should be the shortest distance between the centers of two pulleys of considerably different diameters, belted together? W. T. K.

Twice the sum of the two diameters is used by many engineers as the minimum allowable distance; if the diameters are greatly different, we would prefer to make it equal to the sum of the pulley circumferences.

What type of engine is preferable for driving a 2200-volt 120-kw. alternator? (2) Which is preferable for such a case, belt drive or direct connection? (3) Will a 75-ampere double-throw switch be suitable to connect the generator to either of two sets of bus-bars? J. C. F.

This depends largely upon local operating conditions. Speaking generally, a medium-speed, four-valve engine would be suitable; no hard-and-fast rule can be given. (2) Unless floor space is restricted, belt drive. (3) Yes; it must be a double-break switch, of course, the blades being "dead" when not in either set of jaws.

Two transformers with primaries connected to two phases of a three-phase line and secondaries in parallel on both sides of a three-wire secondary system blow fuses as soon as the secondary switches are closed. Why? (2) Cannot the load be distributed by two incandescent-lighting transformers on two phases and a series arc-lighting transformer on the other? I. W. B.

Because the primary currents are not in phase, so that the secondary currents are also out of phase; as the secondaries are in parallel, one of them is a short-circuit to the other when the current in the first one is at zero; at this instant, the primary voltage of the short-circuited transformer is one-half of its rated voltage. (2) Yes, provided you separate the secondaries of the incandescent-lighting transformers.

How does a "compensated" alternating-current motor differ from an induction motor? (2) What class of work is such a motor used for?
H. D. E.

A compensated motor is a series-wound machine, the armature and commutator being similar to the ordinary direct-current type. The "compensation" consists in providing a source of magnetism which neutralizes the electromagnetic reaction of the armature upon the main or working field.

The Thompson-Ryan dynamo is a "compensated" machine, although built for direct-current generation. (2) The alternating-current compensated motor has not come into commercial use to any considerable extent in this country; it is a very recent development. It is especially well adapted to railway and similar classes of service.

What is the work done by a water motor in a stroke of 7 inches, the piston being 4 inches in diameter and the water pressure 120 lbs. per sq. in.? (2) In Ayrton's "Practical Electricity" it is stated that the rate of work in an electrical circuit is $I^2 R$ when there is only resistance in the circuit, but when there is any counter e.m.f. the watts are greater than $I^2 R$, so that $I^2 R$ is less than $I E$. Why is this? R. H. M.

The foot-pounds of work done by a piston under pressure is equal to the pressure per unit of area, multiplied by the piston area and by the distance traveled in feet. In your case, the specific pressure is 120 pounds, the area is 12.566 square inches and the travel is 7/12 foot; hence, the work done is 879.65 foot-pounds. (2) Because there is the counter e.m.f. to be overcome, in addition to the circuit resistance. The watts represented by I^2R are only those expended in overcoming the dead resistance.

A wattmeter plate is stamped "Volts: 110; amps. 300; cycles: 60; secs.: 540." What does "secs. 540" mean? T. C. R.

The instrument is evidently a Stanley watt-hour meter; the inscription "secs. 540" means that in 540 seconds, with a constant load, the revolutions of the disc multiplied by the gear constant (100) will equal the watts passing through the meter. Nine minutes, however, is a rather long test for the disc-revolution method; a convenient way would be to test the meter exactly one minute, in which case the watts in the circuit will be

900 × *total disc revolutions = watts.*

In other words, count the disc revolutions for exactly one minute, deduct 10 per cent. from the number, and the remainder will be the *kilowatts* in circuit.

Why does a motor increase its speed when its field is weakened? (2) Why does shifting the position of the brushes cause a change in speed?
N. J.

Because there is no other way in which it can generate the required counter e.m.f. The counter e.m.f. must be enough to make up the difference between the drop in the armature and the e.m.f. applied to the brushes; it is proportional to speed, number of armature wires and field strength. With a certain applied e.m.f. and load, a certain counter e.m.f. must be generated, and if the field strength is changed, the speed will change automatically so as to make up for the change in field. (2) Because it alters the effective number of armature wires and thereby the counter e.m.f. that can be generated at a given speed; if the effective number of wires is decreased by shifting the brushes, the speed will increase to compensate for it.

In a 1000-volt alternating-current system supplying incandescent lamps only, is there any choice between 60 cycles and 125 cycles frequency? (2) If it should be determined to change a system from 125 to 60 cycles, would it be allowable to install the 60-cycle generators without changing the distribution circuits and transformers? (3) What is the effect of operating a 125-cycle transformer on a 60-cycle circuit? J. M. D.

Not so far as immediate conditions are concerned, but in order to be in position to supply motors in the future it is preferable to install 60-cycle apparatus in a new plant. (2) If the voltage is the same, and the transformers are of modern construction, yes; but any transformers more than five years old should be displaced by modern apparatus. (3) The heating is greater and the internal losses are, therefore, greater; this is due to the increase in magnetic flux in the core, causing larger core losses and slightly larger copper loss. A modern 5-kw. transformer, for example, has a full-load efficiency of 97.1 per cent at 125 cycles and 96.8 per cent at 60 cycles; the half-load efficiencies are 97.2 per cent at 125 cycles and 96.5 per cent. at 60 cycles.

What is the principle of an ammeter shunt? (2) How can a shunted ammeter register the full current? (3) Why are shunts used? J. H.

(1 and 2) The shunted ammeter is based on the principle of divided circuits. The ammeter and its shunt form two parallel branches of widely different resistances, the shunt being of much lower resistance than the ammeter winding. If the ratio is 1 to 99, for example, the current in the shunt will be 99 times the current in the ammeter, no matter what the total current may be; the ammeter, in such a case, would be calibrated to indicate 100 times the current actually flowing through it, since the total current is 100 times that in the ammeter winding. Thus, if the circuit current is 10 amperes, 9.9 amperes would flow through the shunt and 0.1 through the ammeter; the dial would be so marked that with this current the needle would point to 10. If the line current be doubled, the current in the ammeter will be doubled, and the pointer will indicate 20. (3) To avoid passing heavy currents through the moving parts of the ammeter.

How can I recuperate old sal ammoniac batteries? (2) How does a booster operate in connection with storage batteries? E. H. B.

If replenishing the solution does not bring them up, you need either new zincs or porous cups (if the battery is that type) or both. (2) Boosters and storage cells are usually employed in conjunction with compound-wound dynamos which increase the line pressure as the load increases. The arrangement may be such that at no load the booster is idle and the dynamo e.m.f. is sufficiently higher than that of the battery to force the maximum charging current through it; as the load comes on, the dynamo e.m.f. rises and the booster (in series with the battery) commences to supply e.m.f. agreeing with the battery e.m.f.; the booster e.m.f. rises more rapidly than that of the dynamo, so that when the latter reaches full load, the sum of the booster and battery e.m.f's is about equal to that of the dynamo, preventing any current from passing backward through the battery; any increase beyond full-load current increases the booster e.m.f. so as to cause the battery and booster to take the surplus load.

A NEW SINGLE-PHASE RAILWAY SYSTEM.

A most interesting exhibition was given on August 19, on the Ballston extension of the Schenectady (N. Y.) Railway, of a single-phase, alternating-current railway motor equipment built by the General Electric Company. A party of technical journalists attended the trial by courtesy of the General Electric Company, a special car being taken up to Schenectady on one of the New York Central Railroad express trains for the purpose.

The new car equipment possesses the highly advantageous feature of operating on either alternating or direct current, the motors being designed for the standard direct-current voltage (500-600 volts) and step-down transformers being employed to reduce the trolley-line e.m.f. of 2,000 volts to a secondary e.m.f. of 400 volts. The G. E. single-phase motor is a series-wound compensated commutating machine, very similar in outward appearance to the ordinary direct-current railway motor, as Fig. 1 shows. The field magnet, however, is similar in construction to the stator of an induction motor, consisting of a laminated ring with slots all around the interior for the reception of the windings. The latter are distributed, like those of an induction motor, and are arranged almost exactly like the windings of a two-phase motor, one winding giving the main "working" field and the other neutralizing the effect of the armature ampere-turns.

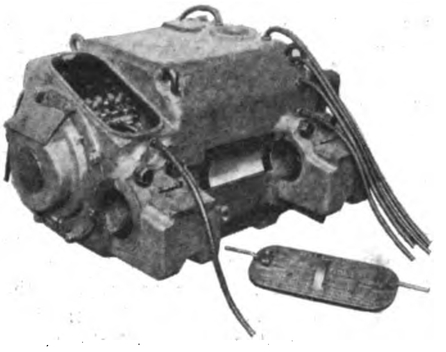

FIG. 1.—SINGLE-PHASE RAILWAY MOTOR.

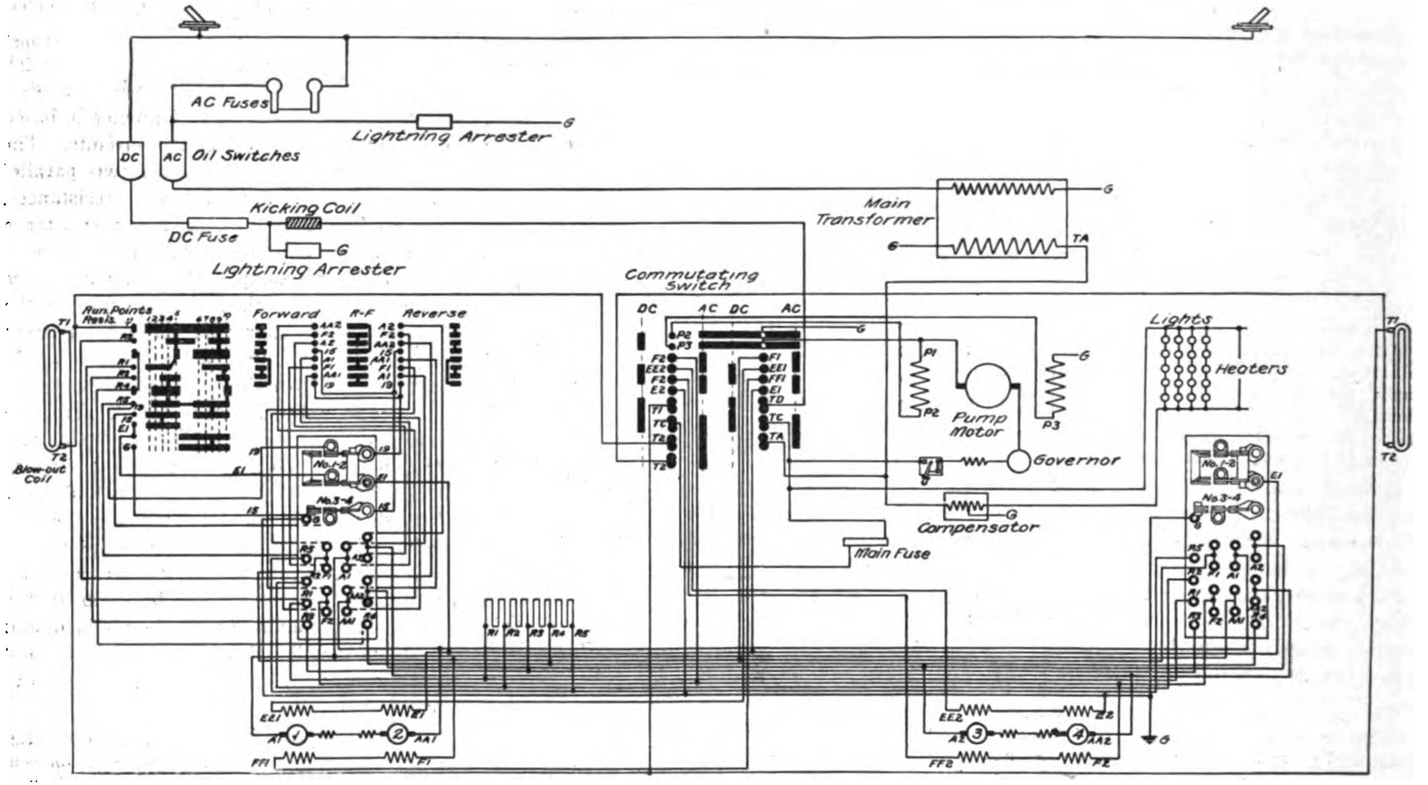

FIG. 2.—CAR WIRING WITH FOUR MOTORS FOR ALTERNATING AND DIRECT-CURRENT OPERATION.

The armature is of the closed-circuit type used in direct-current motors; no auxiliary appliances, such as high-resistance leads to the commutator, being employed to reduce the inductance. In operation on alternating current, the machine sparks slightly at the brushes, but the sparking seems to have no deteriorating effect whatever upon the commutator. On direct current, the operation is absolutely ideal; there is no difference in the appearance of the commutator and brushes from their appearance at standstill. As the accompanying charts show, the motor has about 95 per cent. power factor under normal running conditions on alternating current.

The car equipment exhibited on the occasion referred to above comprised four motors connected up in two pairs, each pair permanently in series; an ordinary direct-current series-parallel controller, a throw-over switch for changing the connections from the direct-current to the alternating current arrangement and an 80-kw. air-blast transformer. The commutating or throw-over switch puts the field windings of each pair of motors in series for operating on alternating current and in parallel for direct-current operation, and also cuts out the transformer in the latter case; otherwise the connections of the machines are identical for both systems. The commutating switch is interlocked with two main oil switches, one being in the high tension alternating current, and the other being in the direct current circuit, this interlocking being so arranged that only one switch can be closed at a time and the commutating switch can only be thrown when the main line oil switches are in the off position.

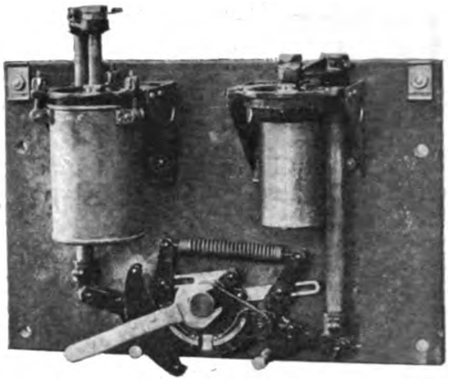

FIG. 3.—OIL-BREAK MAIN LINE SWITCH.

Owing to the fact that the alternating current trolley wire of the Ballston line is off center, while the standard direct-current city and suburban trolleys are directly overhead, it was necessary to provide two sets of trolleys, one for the alternating-current and the other for the direct-current system, hence the necessity for interlocking the oil switches and commutating switch to pre-

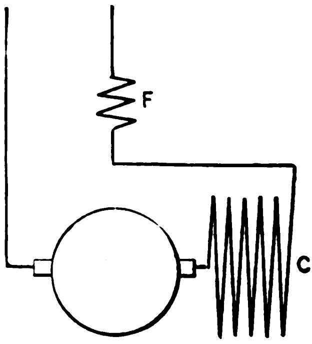

FIG. 4.—DIAGRAMMATIC REPRESENTATION OF CIRCUITS OF COMPENSATED MOTOR.

vent trouble should both trolley poles accidentally be up at the same time. Where center wire construction is used on both the city and suburban sections, the alternating current and direct-current trolley wires may be overlapped for a short distance to facilitate changing from one trolley to the other.

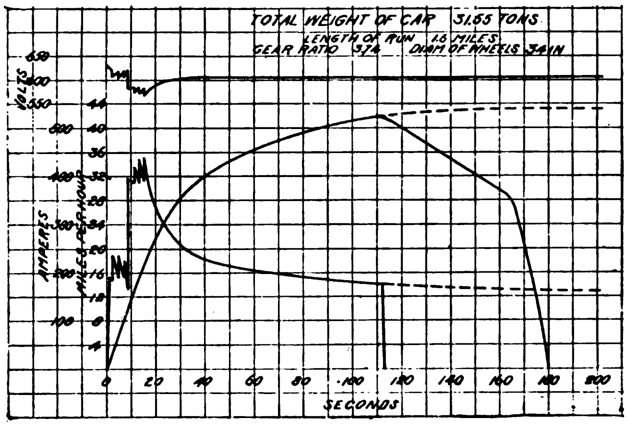

FIG. 5.—OPERATION OF FOUR-MOTOR EQUIPMENT ON DIRECT CURRENT.

With modern suburban cars, especially those equipped with train control, air brakes, air compressors, etc., there is some difficulty in suitably locating the proper apparatus, even when equipped for direct-current running only. With cars equipped for both alternating-current and direct-current running, using series parallel controller, there will be required but slightly more space and weight than for direct-current running only. Should, however, advantage be taken of the slightly better efficiency of alternating current potential control, such cars must be operated alternating current upon both suburban and city sections, with the resulting disadvantages; or the installation of two separate potential methods of control may offer advantages sufficiently great to warrant their adoption.

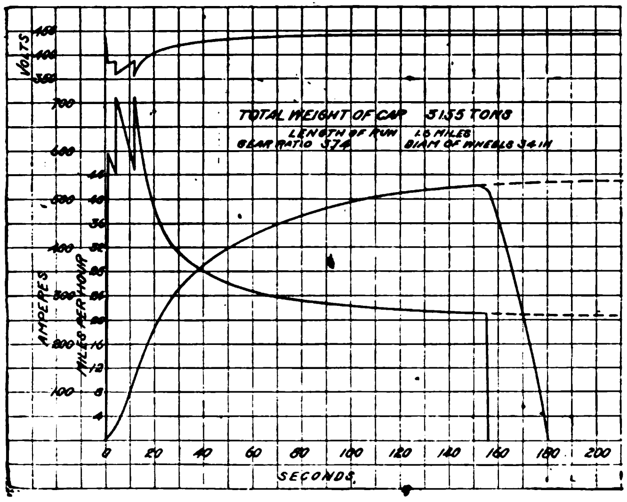

FIG. 6.—OPERATION OF FOUR-MOTOR EQUIPMENT ON ALTERNATING CURRENT.

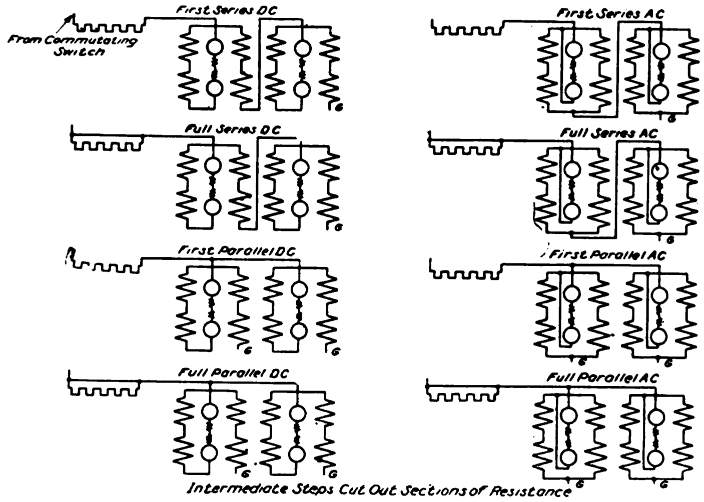

FIG. 7.—CONTROLLER CIRCUITS FOR FOUR-MOTOR EQUIPMENT.

The car equipped with the compensated motors weighs 30.4 tons total, without passengers, and is geared for a maximum speed of 43 miles per hour on the level. It is a Brill car, with a 32-ft. body, or forty-three feet over all, and has a seating capacity of forty-four passengers. The body is mounted upon Brill No. 27 trucks having six-foot wheel base, each truck carrying two compensated motors; each motor is equivalent to a 50-h.p., direct-current motor, standard railway rating.

All speed-time runs taken on the Ballston line were made over a distance of 1.6 miles on tangent level track at an average speed of thirty-two miles per hour, or a schedule speed of 29.5 miles per hour, including fifteen-second stops. The compensated motor equipment has thus demonstrated its ability to make as high schedule speed as any suburban road now operating direct-current equipments under like conditions.

The compensated motors run the car at practically the same speed with 200 volts per motor alternating current and 300 volts direct current. This uniform speed is obtained by series paralleling the field.

Center pole bracket construction is used, there being two brackets supporting the two 600-volt direct-current trolley wires and a crossarm supporting the two 2,200-volt alternating-current trolley wires. The Ballston extension has been operated for several months with direct-current equipments, and their operation being continued in part necessitated an additional set of trolley wires for the alternating-current equipments which would not interfere with the direct-current trolleys. The direct-current trolley conforms to standard bracket construction and presents no unusual features, while the alternating-current trolley wire is suspended from a ⅜-inch steel catenary. The alternating-current trolley is clipped to the catenary midway between poles and the catenary in turn is hung over porcelain insulators on wooden cross arms, the whole forming a construction of great flexibility with the further advantage of providing excellent insulation with standard porcelain insulators and eliminating the span wires adjacent to the trolley wire, thereby preventing the pole catching should the trolley wheel leave the wire. This method of trolley construction is well adapted to high potential, high-speed work in both its electrical and mechanical features.

With the alternating-current system using a trolley and track return, there is an inductive drop in the trolley and rails, with an additional loss in the latter case due to eddy currents and hysteresis. Measurements made upon the Ballston line indicate an apparent trolley resistance of 1.3 times the ohmic resistance, and a rail resistance 6.55 times the ohmic resistance.

Owing to the fact that 25-cycle, three-phase generators are almost universally used to supply rotary converters in existing interurban railway systems, the General Electric Company has adapted the designs of the compensated motor and the alternating-current distributing system to operate from existing 25-cycle generating stations. As the alternating-current motor is single-phase, a single-phase generating and distributing system commends itself on account of its simplicity. The step-down transformers may be tied together on the low-tension side through the trolley, with consequent reduction in amount of copper required. Each sub-station acts as a reserve to the adjacent one and a transformer may be cut out without shutting down a trolley section.

The single-phase alternating compensated motor system is the outcome of years of study and development and is the work of no one person. Mr. William B. Potter, chief engineer of the Railway Department of the General Electric Company, has directed the study and building of the equipment. As the head of the railway department he has personally been responsible for the work. Closely associated with him, an able corps of engineers has been studying the various branches. Mr. A. H. Armstrong has been one of his most valued assistants; another important assistant is Mr. Walter J. Slichter. Prof. Charles P. Steinmetz has given the system considerable study, and his able advice has been of the greatest assistance. Mr. F. E. Case has been interested in the working out of the controllers, and Mr. E. D. Priest has had charge of the perfection of the motors; Mr. Priest in turn has been assisted by Mr. E. H. Anderson.

New Apparatus and Appliances

NEW FORMS OF INCANDESCENT LAMP RECEPTACLES.

The H. T. Paiste Co., of Philadelphia, Pa., manufacturer of the "P-K" receptacles, has recently added two new receptacles to its well-known line of Fielding receptacles. These are designated as "show window receptacles," and are stated to be especially well adapted for display work. They are provided with smaller bases than the regular Fielding receptacles, the straight type shown by Fig. 1 measuring 1½ x 1½ ins. The 60-degree angle receptacle shown by Fig. 2 has a base 2 x 1½ ins. This permits of their being placed much more closely together and enables greater lighting effects to be obtained in a given space. The receptacle shown by Fig. 2 holds the lamp and reflector at an angle that throws all the light upon the articles making up the window display.

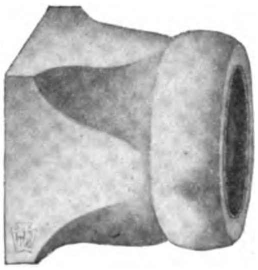

FIG. 1.—SHOW-WINDOW RECEPTACLE.

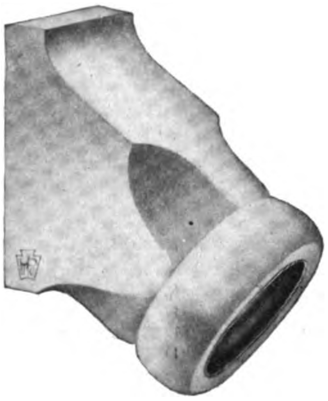

FIG. 2.—SIXTY-DEGREE SHOW-WINDOW RECEPTACLE.

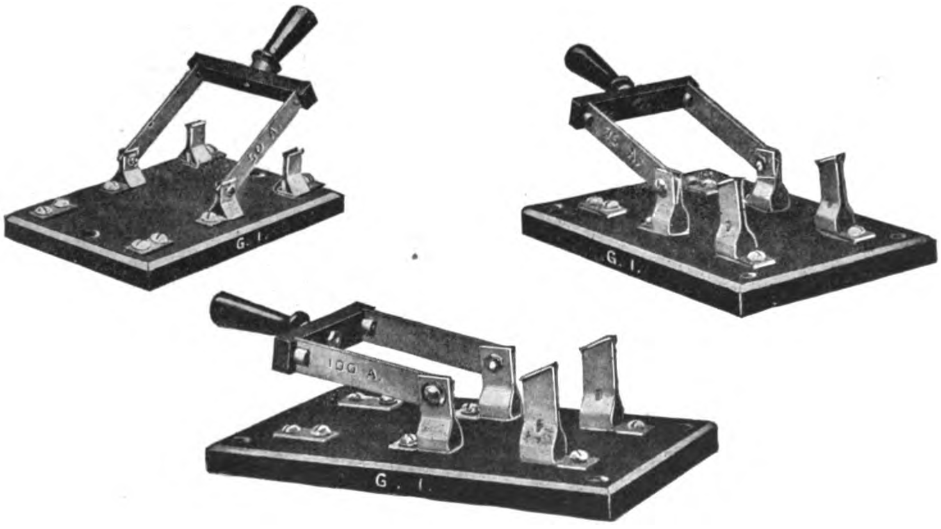

FIG. 3.—PUNCHED CLIP LEVER SWITCHES.

PUNCHED CLIP LEVER SWITCHES.

The General Incandescent Arc Light Company, of New York, has recently brought out a line of lever knife switches designed especially to meet the demand for a cheap, well-made switch for motor or lighting service in factories or similar installations. These are well made, all of the conducting parts being of pure rolled copper, finished by dipping and lacquering on slate bases. The line of switches is made entirely front-connected, lugs but no fuses being furnished in every instance unless otherwise specified. The switches are designed to meet all requirements excepting where highly polished switches are desired. They are furnished in one style of finish in the following sizes: 15, 25, 50, 75, 100 and 150 amperes; 1, 2 and 3-pole, with and without fuses, and single and double-throw, set for 250-volt service.

NEW INSTRUMENTS OF PRECISION.

The Westinghouse Electric & Manufacturing Company has developed a new line of electrical measuring instruments of precision which are said to combine the accuracy of the best known standards with the portability and rapid and easy manipulation of the ordinary testing instruments now in use. The advantages of both types have been retained, it is stated, with the elimination of those features which detract from their value in general use.

The Westinghouse Company further purposes to secure to purchasers a continuation of the initial accuracy of these instruments by keeping them in calibration for five years without charge. Special shipping cases are provided to minimize the labor of packing and shipping. At any time within the period named customers may ship these instruments to the Westinghouse Department of Standards to be checked, and the work will be done promptly, with no cost to the owners except that for transportation.

The illustrations show a voltmeter, an ammeter, a wattmeter and a resistance or multiplier used with a voltmeter or a wattmeter. The voltmeter is exactly similar in appearance to the ammeter, excepting the terminal posts. The mechanism is mounted in a cast-iron frame of a high resistance alloy, and suspended from the top plate. This is made of black enameled slate, giving a rigid construction and not affected by warping or changes in temperature. In principle, these instruments are fundamentally electrodynamometers. The two coils are so arranged as to neutralize the mutual induction and the effect produced by any external field. The readings are thus equally accurate with direct or alternating currents, and there is no necessity for reversing the readings on direct currents, as with ordinary standards.

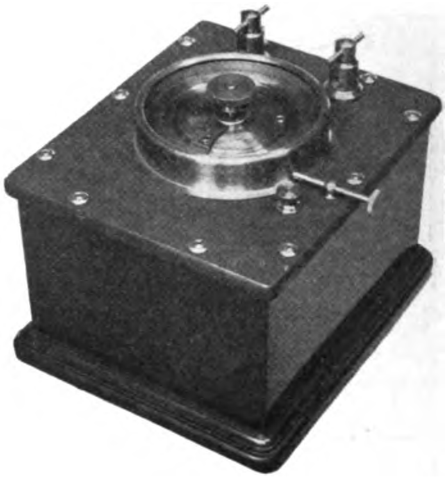

FIG. 4.—AMMETER.

The controlling force is very large, rendering negligible any friction effects, and obviating the disadvantage found in instruments having a controlling force so slight that the static attraction produced by rubbing the glass over the dial will introduce an error. The voltmeter dial here illustrated shows the general form used in the different instruments. The scale is graduated upon a five-inch circle, all the divisions being uniform. By means of a vernier, tenths of a division may be read, giving a range of 20,000 readable divisions.

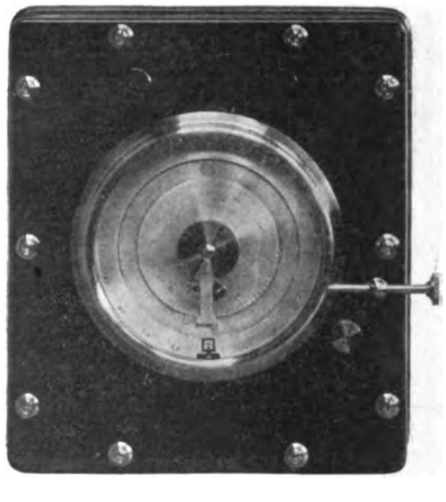

FIG. 5.—VOLTMETER.

The sight wire is shown in a square frame which is attached to the movable coil of the instrument. When current passes through the windings, the sight wire is carried to the right of the zero mark.

By means of the large central knob the vernier is turned to the left until the sight wire is approximately upon zero, a finer adjustment being obtained by the knob upon the right. The voltmeter and ammeter dials are similar. The inner graduations are so spaced that their value is proportional to the square root of the deflection, allowing readings to be taken direct, without calculation. When readings of fractional parts of a division are required, the outside scale with the vernier may be used and the corresponding value of the reading on the inner scale determined from the table of square roots furnished with each instrument. In the wattmeter there is but one set of graduations, similar to those shown on the outer circle of the voltmeter scale. The potential coils of the voltmeter and wattmeter are adjusted to a uniform resistance of 100 ohms, and the external resistance or multiplier is subdivided so as to give total values of 1000 ohms or multiples thereof. A total resistance of 1000 ohms is employed for each 100 volts nominal potential. The resistances are accurately checked, and thus form standards of resistance as well as measuring instruments. As the same values are used for both the voltmeter and the wattmeter potential circuits, one resistance will answer for both instruments. The facilities afforded for accurate observation are worthy of special mention; the fineness of the sight wire, the narrow, even, machine-cut division lines of the scale and the open divisions of uniform length make it easy to take extremely accurate readings at any point on the scale.

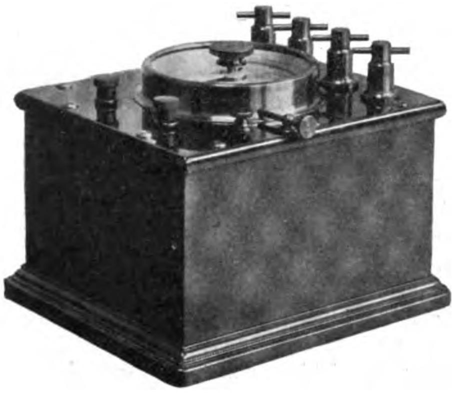

FIG. 6.—WATTMETER.

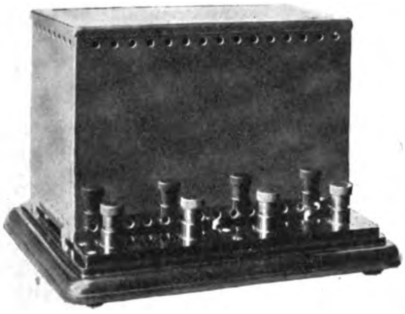

FIG. 7.—RESISTANCE FOR POTENTIAL CIRCUITS.

CLIMAX ENCLOSED ARC LAMP.

The new form of enclosed arc lamp herewith illustrated has been brought out under the name of "Climax" by the Keystone Electric and Manufacturing Company, Allegheny, Pa. Figs. 8, 9 and 10 show it complete and in detail. A special feature shown in Fig. 10 is the regulating coil made by machinery designed for the purpose. A flat copper strip is wound spirally about a solid mica core and each layer of the spiral is separated from the adjacent layer by mica washers. The spiral is then surrounded by another mica tube, and all is encased in a metal tube, with metal heads, to which are fastened the necessary terminals and a clamping device with which to adjust the coil. The whole forms a solid fire-proof coil. Fig. 8 is a view of the mechanical movement of the lamp, with the dash-pot and the flat spiral connectors. The upper carbon holder and the carbon-carrying tube have but one motion and cannot be turned, avoiding disarrangement of the spiral conductor during operation. In the direct-current lamp the dash-pot is constructed with a loose-fitting piston of large diameter in the gas diffusing chamber. The piston is fastened to the clutch plate in such a manner as to have a lateral motion, thus permitting it to find its own free path and avoiding all possibility of wear and sticking due to friction. The enclosing globe cap forms the bottom of the gas-diffusing chamber and dash-pot, and carries the insulating, bushing and negative carbon support. It is held in place by two outwardly swinging arms engaged by two lugs on opposite sides of the gas chamber and fastened by thumb nuts. The clutch is composed of two cast-iron parts—duplicates—hung on two cotter pins in such a manner that when they fall toward each other the opening becomes less than the diameter of the carbon. Hence, when the clutch plate is raised they grip the carbon. The porcelain resistance holder has a thread moulded on its outer surface, in which the wire is wound. A clamping device is placed to one side, with a sliding member, by which the adjustment for proper arc voltage is achieved. The company also furnishes an external resistance, in a separate case, for 220 to 250-volt lamps, which may be placed at any convenient point; or the lamp may be suspended from it. A switch is provided in the top of the lamp. The housing is made of copper and riveted, no solder being used on any part of the lamp. The outside globe holder is fitted to an internal sleeve of the main shell by three bayonet locks, and is easily removed or replaced. Housings of steel or brass can be furnished, if so desired. The inner globe is of large diameter, allowing the whole hand to enter for cleaning. It is of the closed end type, and is readily removed and replaced when trimming.

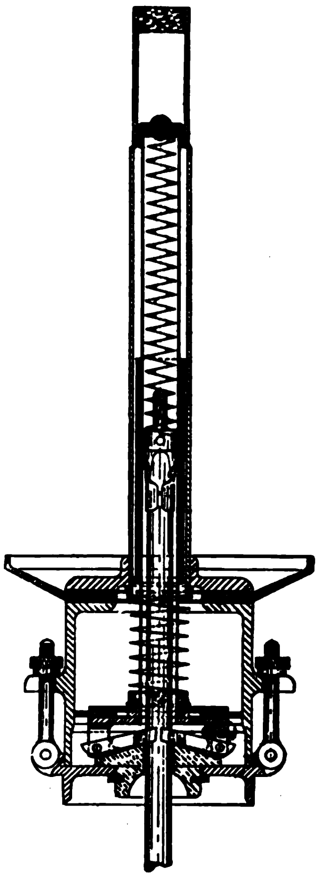

FIG. 8.—DASHPOT MOVEMENT.

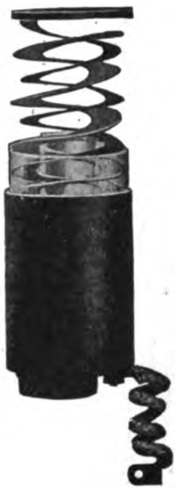

FIG. 10.—REGULATING COIL.

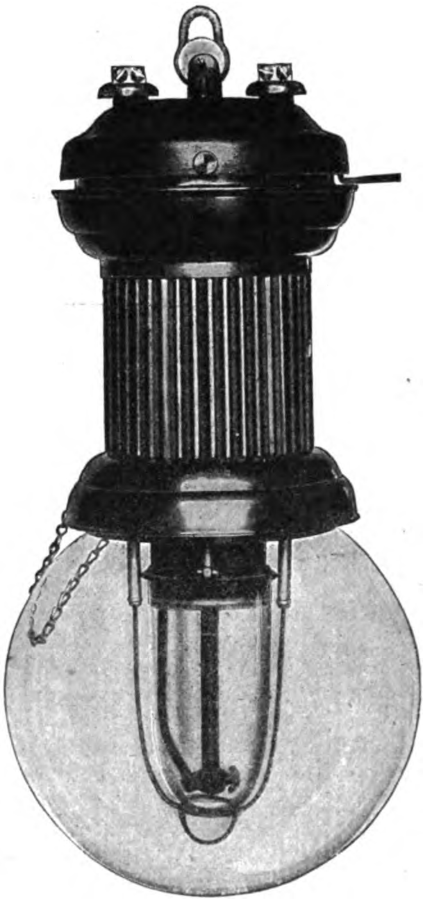

FIG. 9.—ENCLOSED ARC LAMP.

IMPROVED MOTOR-DRIVEN DISC FANS.

Fig. 11 herewith shows an improved disc fan made by the American Blower Company, of Detroit, Mich., direct-connected to a Westinghouse motor. The fan is a modification of the American Company's well-known "A B C" fan, and the motor instead of being attached to the arms of the fan, as has heretofore been customary, is placed upon a substantial base, resulting in a combination of rigidity and compactness. The series-wound, multipolar form of motor is used, except for the very small machines, which are made bipolar. Free ventilation is made possible by the general design. The bearings are self-oiling and the machine requires a minimum of care and attention during operation. The open type of motor shown in Fig. 11 is usually furnished. Enclosed motors may, however, be obtained when conditions require their use. Each motor is furnished with an automatic release switch and a fireproof rheostat.

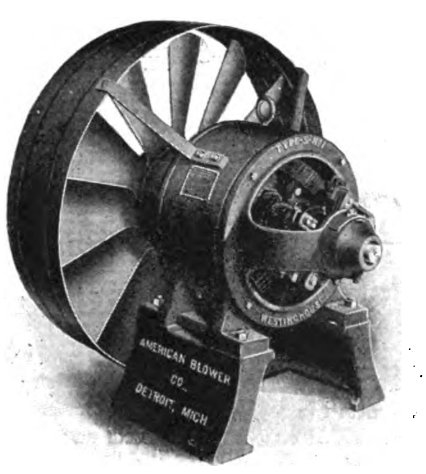

FIG. 11.—MOTOR-DRIVEN DISC FAN.

CALIFORNIA WATER POWERS AND WATER WHEELS.

Of the many natural advantages furnished by the State of California, not the least is its numerous waterfalls. They are not generally of the spectacular order, as Niagara, although, in the Yosemite Valley and other parts of the State, one may find some waterfalls which rival in grandeur that famous sight. Hundreds of miles of pipe lines traverse the State and make possible the utilization of water under pressures heretofore unheard of in actual practice. As an instance may be cited the plant of the Edison Electric Company near Redlands, in the Southern part of the State, where a Pelton water wheel is operating under a head of 1950 feet—equivalent to 850 lbs. pressure per square inch. This wheel is direct-coupled to an alternator and has 1000 horse-power capacity. The station is only one of many controlled by this company, which has a large number of Pelton wheels in use under heads ranging from 100 feet up to the figure just named—1950 feet. It is interesting to note that under such extreme pressures the water issuing from the nozzle is so dense that a sledge hammer will have no effect upon it; this has been demonstrated by actual experiment. Obviously, the nicest mechanical workmanship and design are required to construct a wheel to withstand such severe conditions. The demands for cheap power, together with the advantages of water at hand, have naturally led to the development of a water wheel to supply the connecting link, and it was a pioneer Californian, L. A. Pelton, who first conceived the idea of a water wheel to operate under high heads. In the "days of '49" the Pelton wheel was called the "Hurdy-Gurdy" wheel, and consisted of a wooden rim, to which were bolted cast-iron "buckets," as they are technically called. Later on the fundamental patents were acquired by The Pelton Water Wheel Company, of San Francisco, who, by experiment, further developed the original idea—of course, making radical changes in design and construction—and succeeded in producing a wheel from which remarkable results are obtained. An efficiency of 90 per cent. has been reached by this wheel in tests which, however, were made on wheels operating under the most favorable conditions; but efficiencies of 80 and 85 per cent. are said to be realized in ordinary practice.

The Pelton Water Wheel Company has built up a large industry in the manufacture of water wheels. In the last sixteen years there have been installed over 11,000 Pelton wheels, aggregating over 1,000,000 horse-power, and ranging from a fraction of a horse-power up to 10,000 horse-power per wheel unit. It is interesting to note that one may find this California machinery product in use driving fans in a bungalow in India as well as operating a 30,000-h.p. electric plant in Oregon.

NEW BOOKS.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Second Edition. London: *The Electrician* Printing & Publishing Co., Ltd. New York: D. Van Nostrand Company. 217 pages, 8½ ins. x 5¼ ins. Price, $3.50.

This book bears no date, either on the title page or at the end of the preface, which omission is frequent with books published of late years, especially by the London publishers of this work. This is a pity, for the omission of a date actually depreciates the value of any book, but more particularly a technical book pertaining to a subject in which rapid progress is being made.

As is indicated by the title, this book is for beginners, the treatment of the subject being somewhat more elementary than that of the "Student's Guide to Submarine Cable Testing," by Fisher and Darby, brought out by the same publishers. It is, nevertheless, a very good book, within its chosen field, giving satisfactory accounts of many tests; the description of the Ayrton and Mather or "universal" shunt might, however, be clearer. It seems as though the principles of this shunt might be expounded in a manner that is not only lucid but luminous, using only language adapted to a work like the present one, intended for beginners; yet the reviewer has never seen an exposition that was entirely satisfactory.

Mance's method for measuring the internal resistance of a battery by means of a Wheatstone bridge is another matter that is not usually treated with sufficient perspicuity; in this book, the treatment is perfunctory or even slovenly; there is no intelligible explanation of the rationale of the method. The reviewer remembers the difficulty he had, when a student, in understanding Mance's method, although the ordinary Wheatstone bridge and Kelvin's method for the resistance of a galvanometer were perfectly clear. It is possible, however, to make Mance's method clear by a brief explanation. Schaffer's test for locating a break is treated somewhat fully, the author preferring it to Mance's or Kennelly's tests. This test is not described in Fisher and Darby, and not so well handled in some other books. All the more important tests used in cable work are treated in the book under review, some of them in a very satisfactory manner—a manner adapted to the requirements of the class of readers for whom the book was written.

ELECTRIC MOTORS. By H. M. Hobart. New York: The Macmillan Company. 1904. Cloth; 458 + X pages, 5½ ins. x 8½ ins.; 480 illustrations. Price, $5.

One of the peculiarities of all textbooks on the principles of dynamo design or construction or both is the lack of adequate information regarding motors; the present volume, therefore, is amply justified, and, as might have been expected by reason of the author's high standing as a designer, it represents a very efficient effort to supply the deficit in its class of literature. That the book does not cover the subject with absolute completeness is undeniably true, but it does cover a tremendous scope and is of the highest merit as far as it goes. Among the many "points" in motor design which are never discussed in books on dynamo design and are thoroughly covered in the work under review may be mentioned the relation between brush position and speed regulation (p. 7), precautions to be taken in designing an open motor so that it may have as high a rating as possible when enclosed (pp. 13-15), stray losses in commutation (pp. 34-36), and the analysis of a design with relation to the cost of construction (pp. 108-111).

A drawback in the author's method of treatment is his apparent aversion to formulas and definite or specific advice; here and there throughout the book one is also hampered by empirical statements without any explanation of their basis. Thus, in Chapter III, Fig. 16 shows the corrected magnetic density in armature teeth for three values of the ratio of slot width to tooth width and for a certain quality of steel, but the formula by which the chart is calculated is not given, and the chart is worthless for any considerable different width ratios or steel qualities. On page 25 the author allows 20 per cent. increase in the number of active teeth per pole, over the number actually under the pole, for fringing, but does not state why this proportion is chosen; nor does he say why 10 per cent is taken as the increase due to spreading in considering the 35-h.p. design on page 177. On page 33 he says: "There have now been set forth not only methods for calculating all the magnetic circuit proportions, but also all the component losses which determine the efficiency at various loads; the reviewer is unable to find any justification for this statement. Illustrations of the calculation of the magnetic circuit, etc., are given, but these involve empirical practice which is not explained, nor are any formulas or data given which would enable one to follow the author's method in designing machines differing widely from those used as illustrations. The explanation of the author's method of computing reactance voltage of a short-circuited coil is very clear, but it should have been summed up in the shape of a formula. No intimation is given as to whether the reactance voltage should be restricted to 2 volts or allowed to reach 10 volts or some other figure, beyond the fact that it does not exceed 4.4 volts in any of the described designs and is below 3 in most of them. "A wide interpolar space and low reactance voltage" are recommended, but the author gives no idea as to his definition of "wide" and "low." But what *is* said is extremely meritorious and helpful. The examples of motor design are valuable, and the author's illustration of the working out of a 35-h.p. design, Chapter X, is particularly fine. The discussion of variable speed motors, in Chapter XI, is also good.

The second half of the book is devoted to alternating-current motors, and the treatment of induction-motor design is eminently practical, although open to the same criticism as his treatment of the direct-current machine, *i. e.*, there are not enough formulas and definite advisory statements.

In conclusion the reviewer wishes to emphasize the fact that the foregoing criticism is offered with the most friendly intentions and not with the slightest desire to find fault in a carping spirit. The book is far and away ahead of anything thus far published in English on the subject.

SOME EXHIBITS AT THE ST. LOUIS EXPOSITION.

NATIONAL ELECTRIC COMPANY, Milwaukee, Wis., has installed a 1500-kw., alternating-current generator in the exhibitors' power plant. A description of this alternator was given in the May number of THE AMERICAN ELECTRICIAN. In the company's exhibit in Electricity Building an opportunity is given to study the features of construction of this company's electrical machinery. A 400-kw., direct-current generator is shown, which is representative of the company's direct-current construction for the larger units. This has pole tips of soft laminated iron which are bolted to cast field cores and serve to hold the field coils in place. Considerable space is allowed between the series and shunt coils of the fields, so that air can circulate between the coils and permit them to be run at a higher current density without overheating. The armature coils are formed from copper strips or bars, but there is no riveted or soldered joint at the end opposite the commutator. The form of coil has been adopted which permits the bars to be bent hot and afterward insulated so that no soldering is necessary in the entire coil save where it connects to the commutator bars.

LOCKE INSULATOR MANUFACTURING COMPANY, Victor, N. Y., has a display of high-tension insulators in the exhibit of the Wesco Supply Company, of St. Louis. These insulators are of all sizes, from the smallest telephone insulators to one of 17 inches in diameter and 15 inches high. The latter insulator is designed for working voltages of 80,000 volts and consists of an umbrella-shaped porcelain top surmounting three porcelain petticoats which prevent discharges to the pin.

G. M. GEST, conduit contractor of Cincinnati and New York, has a handsome sample of underground conduit construction work in the court of Electricity Palace. This consists of one-half of a manhole with the tiled cable ducts leading from it. Cable hangers are placed in metal slots imbedded in the brickwork. This hanger, which forms one of the specialties of Mr. Gest, can be put at any height and only the hooks actually in use need be put in place.

H. B. CAMP CO. has an exhibit of conduit ducts in the court of Electricity Palace. One-half of a manhole is shown with a Camp multiple-duct conduit entering it. Besides this, many samples of different duct sections made by the company are shown, including the Camp divided-tile conduit, which can be used either as an unbroken tile or can be split open. Several kinds of bends and straight-line conduit are included in the exhibit.

THE WESCO SUPPLY COMPANY, St. Louis, occupies an area of 5,300 square feet. This contains a number of exhibits furnished by the several large manufacturing companies whom the company represents. One portion of the space is devoted especially to electric railway goods. The Globe Electric Manufacturing Company, of Cleveland, Ohio, has several of its arc and incandescent headlights on exhibition.

THE ALLIS-CHALMERS-BULLOCK 5000-h.p. engine and generator in section 36 of Machinery Building is generally admitted to be one of the most notable and attractive exhibits in the Exposition. The unit was installed not only as an exhibit, but plays an important part in furnishing power for the decorative lighting and for the street railway lines leading to the Exposition Grounds. During the daytime, from 2 in the afternoon until 7 in the evening, current is supplied to the St. Louis Traction Company, the load being about 3,000 horse-power. In the evening the unit carries the current for nearly 200,000 8-c.p. incandescent lamps which are gradually brought from darkness to full brilliancy. At one corner of the exhibit is a large, square cage filled with gridiron-shaped pieces of metal which form the rheostat, the purpose of which is to absorb the current created by the exciter for the generator of the big engine and regulate it until wanted. On the face is an arm which revolves over a large number of contacts. As this makes a turn it cuts out little by little the resistance of the rheostat. This arm is turned by means of a small electric motor on top of the cage. When the time for lighting arrives an operator at the main switchboard touches a button and the little motor begins to move. As the resistance of the rheostat is gradually cut out the whole number of decorative lights over the entire fair begin to glow and gradually gain in volume of light as the arm progresses about the circle. The engine is of the style designed by the Allis-Chalmers Co. for the Manhattan power station in New York. It is capable when worked to its full capacity of producing 8000 horse-power. It is a combined vertical and horizontal compound condensing engine running at 75 r.p.m. under a steam pressure of 150 pounds. The height of the engine above the foundation is 39 ft. 2 ins. Other details are a follows: High-pressure cylinder, horizontal; valves in cylinder; valves and cylinder double ported. Diameter, 44 ins. Low-pressure cylinder, vertical; side-pipe construction; valves in heads; valves double ported; heads single ported. Diameter, 94 ins. Piston rods, high pressure, 9 ins. in diameter; low pressure, 10 ins. in diameter. Steam ports, high pressure, area 150 sq. ins.; low pressure, area 712 sq. ins. Exhaust ports, high pressure, area 206 sq. ins.; low pressure, area 930 sq. ins. Stroke, 60 ins. Shaft, hollow, forged open hearth steel. Diameter, 37 ins. in wheel and generator fits, 34 ins. in main bearing, 32 ins. in outer bearing, 30 ins. in crank hub; hollow, 16-in. hole. Main bearing, 30 x 60 ins.; ball-and-socket type. Outer bearing, 32 x 48 ins.; ball-and-socket type. Crank, fan-tail type, cast steel. Crank pin, nickel steel, 20 ins. diameter, 18 ins. long; common to both high and low-pressure engines. Fly wheel, 25 ft. in diameter; rim, 30 ins. face, 33 ins. deep, built in 10 segments. The whole engine weighs 720 tons; fly wheel, 300,000 lbs.; shaft, 61,000 lbs.; crank, 32,000 lbs., and the total revolving parts, including generator, 514,400 lbs. An Alberger bar-

A GROUP OF EXHIBITS AT ST. LOUIS.

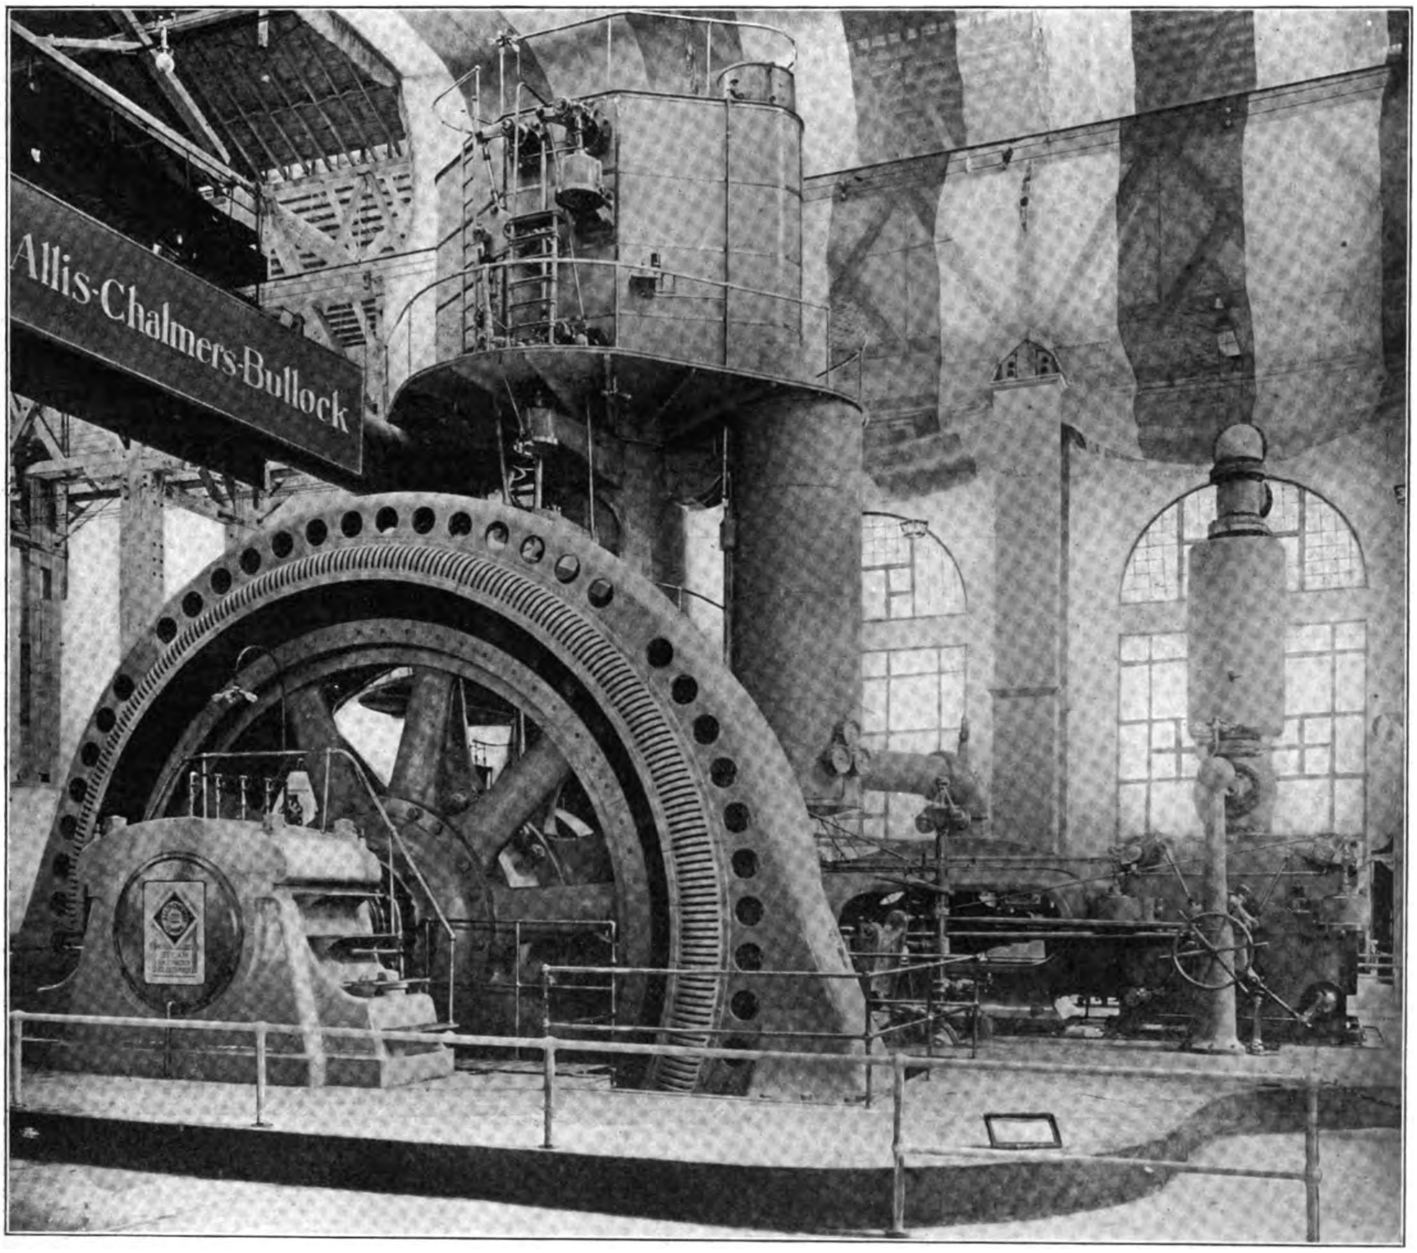
1. **Bullock Railway Motor.** 2. **General Electric Company.** 3. **National Electric** Company. 4. General Electric Company. 5. **General Electric Oil Switch.** 6. **Locke** Insulator Manufacturing Company. 7. **H. B. Camp Company.** 8. G. M. Gest. 9. The Wesco Supply Company.

ometric type condenser is used and the exhaust pipe is 36 ins. in diameter. The regulator of the engine is of the center-weight fly-ball type and actuates a cut-off cam on both the high and low-pressure cylinders. Mounted on the regular cross-shaft is a device for changing the cut-off on the low-pressure cylinder by hand, independent of the high-pressure cylinder. It is also possible to vary the ratio of cut-off between the two cylinders by means of a hand-wheel adjustment on an arm transmitting motion regulated to the low-pressure cam. By these arrangements it is possible to maintain a proper receiver pressure under all possible conditions that may arise in the operation of a larger power unit. The speed of the engine can be increased or decreased several revolutions per minute. This is accomplished by an adjustable weight mounted in a yoke on regulator cross-shaft. By moving this weight in either direction from its central position, which is neutral, the effect is equivalent to increasing or decreasing the center-weight of the regulator. An electric synchronizing device is attached, to be used while operating the generator in multiple with others. A small reversible electric motor is mounted upon the regulator column in a manner similar to the hand speed-changing device previously described. This motor is operated from the main switchboard by means of a double-throw switch. The motor itself forms the weight for varying the speed, and is made to travel in a frame by means of gears and a threaded spindle. When it is desired to get the generator "in step" with others in operation, the switchboard operator can instantly bring the machine to synchronism by means of the switch controlling motor on regulator. An ingenious but simple arrangement is provided to prevent damage to motor or its attachments, if at any time it should be allowed to run to either extreme of its travel. The gear turning on the threaded spindle engages the latter through a clutch, causing the spindle and gear to revolve together, thus preventing the motor from advancing in its mounting, though it may still continue to run. This obviates the use of cut-out switches on the motor, and the only interruption in the motor circuit is the switch on the main board.

The regulator is equipped with belt-rider safety-stop. This acts on the high pressure cut-off cams and prevents the steam valve from opening.

An oil dashpot is attached to the column of regulator, to prevent "hunting" effects while the engine is operating under variable loads. The piston of this dashpot is turned spherical on its face, thus obviating the possibility of bending action between it and bore of pot.

An important feature is a 2-in. by-pass by which live steam can be admitted directly to the receiver of the low pressure cylinder without first passing through the high pressure cylinder. This makes it impossible for the engine to stop on a dead center, for if the high pressure connection rod were at center the low pressure rod would be at right angles to it, and to start the engine



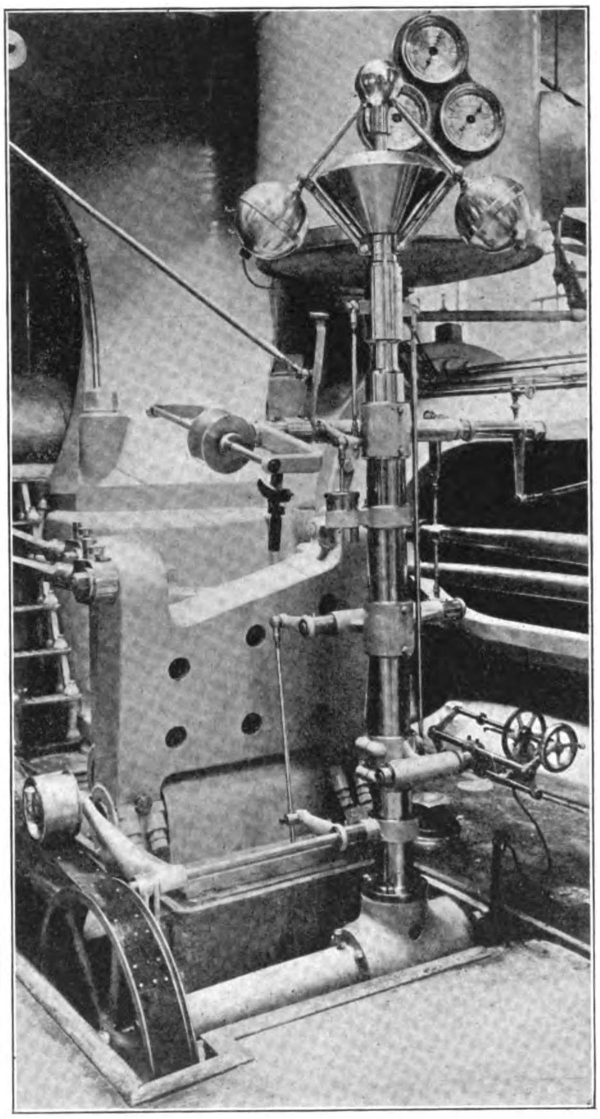
THE ALLIS-CHALMERS-BULLOCK UNIT.

it would only be necessary to open the by-pass valve a little and let steam into the low pressure cylinder. The by-pass has other valuable uses which every practical engineer will appreciate. It is controlled by a valve which is moved by means of a small wheel on a low upright which stands close to the foot of the standard of the throttle operating wheel.

The generator is a 3500-kw. engine type alternator, generating three-phase current at 6600 volts, 25 cycle, and running at 75 r.p.m. It was built by the Bullock Electric Manufacturing Company, of Cincinnati, Ohio.

In the design of this generator have been embodied the most modern practice and engineering skill and many improvements have been introduced. The stator yoke is cast in four sections, securely fastened together by body-bound bolts and held in proper alignment by square splines. These bolts are on the inside of the yoke and give to this machine a graceful and pleasing outline. The casting is cored so as to admit an abundance of fresh air for ventilation through the centrifugal action of the rotor when in motion. The yoke is 27 ft. in diameter, the over-all dimensions being 33 ft. and the casting alone weighing 58,000 lbs. The stator core is built up of mild annealed steel discs 14 mils thick, which are carefully japanned to reduce the eddy currents and again annealed after punching. The dies and punches used to make these laminations are of the modern construction, entirely eliminating the burrs on the outside of the punchings, and therefore no filing is necessary in the slots, which greatly reduces the iron losses. The punchings are rigidly held together by bolts and at frequent intervals are separated by brass castings producing wide air ducts which afford ample ventilation. The pole pieces, of which there are forty, are also built up of laminated annealed steel and held together by malleable iron end plates secured with rivets. The magnetizing coils of the field are made of strip copper wound on edge.

The motor is composed of ten cast-iron arms, securely fastened by heavy cast-iron flanges bolted together. The top of these arms is built up with 1-16-inch punchings, forming a core which is ventilated by two brass spacers each 1¼ inch wide. This core is dovetailed to receive the poles, which are secured by wedge-shaped steel keys. The collector rings are 51 ins. in diameter and are made of copper having liberally proportioned brush surface and separated by a large air space providing ample insulation. The brushholders are of the box construction, carbon brushes being used.



GOVERNOR OF ALLIS-CHALMERS ENGINE.

PERSONAL.

MR. GEO. G. KING has been appointed manager of the Youngstown (Ohio) Telephone Company, succeeding Mr. W. F. Crossley, who resigned the position to accept the State managership of the Colorado Telephone Company.

MR. J. R. BIBBINS, of the Westinghouse Machine Company's staff, read an extremely interesting paper recently before the New England Railroad Club on "The Fitness of the Steam Turbine for Heavy Power Service." The paper has been reprinted in pamphlet form by the Westinghouse Company.

MR. E. W. RICE, JR., the well-known managing director of the General Electric Company, is the subject of a very complete biographical sketch in the August number of Cassier's Magazine. The sketch is naturally highly complimentary to Mr. Rice; it could not be otherwise without inaccuracy.

MR. ED. L. NASH, who has been Eastern sales manager of the Jandus Electric Company for many years, has severed his connection with that concern to accept the managership of the Philadelphia office of the General Incandescent Arc Light Company. Mr. Nash's headquarters are in suite 1208-1209 North American Building.

MR. J. P. GREENWOOD has moved his headquarters from Hattiesburg, Miss., to New Orleans, where he has opened an office in the Hibernia Building. Mr. Greenwood is now district manager for the Electric Machinery Company of Minneapolis, and is also Southern agent for the Reeves Engine Company of Trenton, N. J.

MR. JAMES W. LYONS, formerly manager of the Allis-Chalmers Company's power department, resigned that position last month to accept the appointment of consulting engineer to the Elgin Watch Company, which will erect extensive new works under his supervision. Mr. Lyons' headquarters will be in Chicago, and he will engage in other consulting engineering.

MR. HAROLD R. WELLMAN, for the past five years chief engineer of the motor department of the General Incandescent Arc Light Company, has joined the engineering staff of the Western Electric Company, at Chicago. Mr. Wellman displayed a high degree of ability as a designer of motors of small and moderate sizes while with the G. I. Company, and the Western Electric Company is to be congratulated upon his addition to its staff.

MR. E. R. CARICHOFF, the well-known electrical engineer and expert in electric elevator work, has established an office at 20 Broad Street, New York, and will engage in consulting engineering. Naturally, Mr. Carichoff will make a specialty of electric elevators and motor control, his long experience with the Otis, Sprague and General Electric companies having especially qualified him for these branches. He will also make examinations of inventions and patents.

MR. ROSCOE CORNELL has been appointed manager of the branch office which the Allis-Chalmers Company has just opened in El Paso, Texas. Mr. Cornell goes to the Allis-Chalmers Company from the Mine & Smelter Supply Company, of Denver. He is a graduate of the Michigan College of Mines, and is well known as a mining and mechanical engineer. He has held a number of prominent positions as a mining engineer, and as a smelter and mine superintendent. His acquaintance is extensive, and he is thoroughly qualified to fill the important position to which he has just been appointed.

MR. J. H. HALLBERG, the arc-lighting specialist, has been retained as consulting engineer by the Atlantic Mills, Providence, R. I., where extensive developments are under way. This mill already operates something like 1000 arc lamps, about 1000 incandescent lamps and several hundred horse-power in direct-current motors, and there has now been erected a new power plant containing a 600-h.p. Westinghouse steam turbine, direct-connected to a two-phase, 440-volt, 60-cycle generator, which will furnish power for a number of motors installed in one of the mill buildings. Since Mr. Hallberg has had charge of this plant his recommendations and suggestions, we understand, have been the means of reducing the operation expenses of the present equipment to a considerable extent. Mr. Hallberg is now looking into the matter of electric drive for the various mill machinery in this plant, which will probably require and ultimate electrical equipment of 4000 horse-power.

◆

TRADE PUBLICATIONS.

SMALL DYNAMOS AND MOTORS. Eck Dynamo & Motor Works, Belleville. N. J.—Bulletins 34 and 35, the former containing descriptive material and the latter price-lists of the excellent small machines built by this concern.

BOOKS FOR HOME STUDY. Frederick J. Drake & Co., Chicago.—A catalogue of which the title is partly descriptive. The books listed therein cover almost every subject imaginable from hypnotism to electrical engineering.

AUTOMATIC CIRCUIT-BREAKERS. Ward Leonard Electric Company, Bronxville, N. Y.—Catalogue No. 19,043, in "loose-leaf" pamphlet form, containing illustrations and price-lists of the very complete line of circuit-breakers made by this company.

STERLING BLACK PLASTIC INSULATOR. The Sterling Varnish Company, Pittsburg, Pa.—A series of cards on each of which is presented, concisely but effectively, a strong argument for this new insulating material. A sample of the material is attached to each of the cards.

POLYPHASE REVOLVING-FIELD ALTERNATORS. Fort Wayne Electric Works.—Bulletin No. 1057, containing an illustrated description of the revolving-field belt-driven alternators of this company.

SARGENT AND COCKERILL GAS ENGINES. The Wellman-Seaver-Morgan Company, Cleveland, Ohio.—Two finely-executed books, one containing a brief but well-illustrated description of the Sargent engine and the other a similar description of the Cockerill engine.

SECOND-HAND MACHINERY READY FOR DELIVERY. Joseph H. Thompson, Jr., New York.—This is Bargain List No. 2, consisting of a small pamphlet in which is listed a considerable quantity of steam and electrical machinery and apparatus that has been put in "good-as-new" condition and is ready for immediate delivery.

BULLOCK APPARATUS AT ST. LOUIS. The Bullock Electric Mfg. Company, Cincinnati.—A handsome pamphlet containing illustrations of the Bullock generators, transformers, motors and controllers that have been installed in the Bullock exhibit and elsewhere in the Exposition grounds.

SOCIAL ECONOMICS OF THE WESTON ELECTRICAL INSTRUMENT COMPANY. Weston E. I. Company, Newark, N. J.—This is a beautifully-executed book in which are described very fully arrangements at the Weston Works for the comfort of the employes. It makes most interesting reading.

TESTS OF CENTRIFUGAL PUMPS. De Laval Steam Turbine Company, Trenton, N. J.—Bulletin No. 9, containing a copy of the report of tests made by Profs. Wm. Kent and J. E. Denton of two De Laval centrifugal pumps driven by De Laval steam turbines and one centrifugal pump driven by an electric motor. The results of the tests are presented in full and are extremely interesting.

BOOK OF THE FOUR POWERS. Allis-Chalmers Company, Chicago.—This is a superb specimen of trade literature, as to its execution. It is a handsomely-illustrated book presenting a summary of the scope of the Allis-Chalmers Company's activity. The "Four Powers" are Steam, Gas, Water and Electricity, and the book tells the story in a most interesting style.

AUTOMOBILE SUPPLIES. Electric Appliance Company, Chicago.—This is Catalogue No. 23, of standard size, containing illustrations and prices of spark coils, ignition batteries, electric "flash" lights, gas engine igniter dynamos, spark plugs and numerous other appliances and material which are required to complete the outfits of gasoline and electric motor vehicles.

SUNBURST LAMPS. The Sunbeam Incandescent Lamp Company, Chicago and New York.—This is Catalogue No. 10, containing profusely illustrated descriptions of the line of Sunburst incandescent lamps. The lamps have spherical bulbs, frosted all over except for a small part near the base, and the clear portion is covered by a reflector when the lamp is in the socket. The book is very tastefully executed.

MEYER-GEAR PUMPING ENGINES. Laidlaw-Dunn-Gordon Company, New York.—This is Bulletin L-601 in which are described and illustrated Meyer-gear pumping engines for small water-works and elevator service. They are built in cross-compound and three-cylinder compound types and are said to show a steam consumption of little more than one-half that of the best direct-acting compound steam pumps.

◆◆◆

BUSINESS NEWS.

BROWN CORLISS ENGINE COMPANY, Corliss, Wis., has been awarded the contract for four large vertical cross-compound engines, to be direct-connected to generators at the Washington Navy Yard.

FEDERAL ELECTRIC COMPANY has removed its offices and factory to Girard, Pa., where modern facilities and additional shop equipment will enable the company to increase its output and facilitate the prompt and efficient handling of orders.

THE GENERAL INCANDESCENT ARC LIGHT COMPANY, of New York, furnished the Frank Adams Electric Company, of St. Louis, with all of the oil switches for the distribution of high-tension current in the various buildings of the St. Louis Exhibition. The order was of considerable magnitude.

THE GENERAL INCANDESCENT ARC LIGHT COMPANY, 529 W. 34th St., New York, have been awarded the contract for a large quantity of G. I. arc lamps (110 volts D. C.) for John Wanamaker's new New York store, after very severe competition between the most prominent arc lamp manufacturers.

THE KNICKERBOCKER CONSTRUCTION COMPANY, New York, has been awarded the contract for the installation of the underground and aerial cables for the new Lewiston-Auburn (Maine) Automatic Telephone Company, amounting to over 100,000 feet. The cable is being manufactured by the Stromberg-Carlson Telephone Manufacturing Company, at its Rochester (N. Y.) factory.

THE LOCKE INSULATOR MFG. COMPANY, Victor, N. Y., with an eye to further increase in the voltages for insulator tests, and also to facilitate the systematic study of insulating problems, recently installed a 300,000-volt transformer of 200 kilowatts capacity, the primary of which will be supplied with current from a motor-generator set connected with a neighboring transmission line.

THE B. F. STURTEVANT COMPANY, Hyde Park, Mass., is fitting up quarters in its big plant to be used for an emergency hospital in case of accident to employes. It is to be equipped with all the appliances known to medical and surgical science for the proper care of men who may get injured in the discharge of their duties until they can be removed to their homes. A graduate nurse and medical student will be in charge and a local doctor will attend to all surgical cases.

THE SPRAGUE ELECTRIC COMPANY, New York, which has for many years been identified with the manufacture and installation of electric motors for operating ventilating fans and blowers, reports among recent installations motors driving the ventilating apparatus in the Chicago Post Office and the New York and Brooklyn public baths. In the West 41st Street and East 76th Street public bath there will also be installed two 30 and two 25-kw. Sprague engine-type generators.

THE NATIONAL ELECTRIC COMPANY, successor to the Christensen Engineering Company, Milwaukee, manufacturer of Christensen air brakes and electrical machinery, has just completed extensions of its foundries, and is soliciting orders for open hearth, crucible steel, semi-steel, iron and brass castings. The foundries are equipped with every facility for rapid and economical output, and as the nature of the company's own work demands castings of the highest grade, material furnished on orders will be of that quality.

AMPHIBIOUS CROCKER-WHEELER MACHINES.—The Cudahy Packing Company, Kansas City, Mo., states that it has had another flood in its plant similar to the one that occurred last year, and that both the 350-kw. and the 200-kw. Crocker-Wheeler generators have come through this unusual test successfully again. It was found necessary this time to re-tape the series field coils of the smaller generator, but no other repairs had to be made. Two submersions certainly constitute a severe test for standard machines not intended for submarines.

THE SMALLEST ENGINES AT ST. LOUIS. —Those who visit the big Allis-Chalmers engine in Machinery Hall at the World's Fair, will have an opportunity of seeing beside it the smallest operating steam engines in the Fair. These little fellows, which are made with an accuracy and finish like clockwork, stand in a glass case just across an aisle from the big engine, in the space occupied by the International Steam Pump Company. There are two of them, each working a direct-connected pump and throwing their tiny streams into a copper tank which stands between them.

THE D. & W. FUSE COMPANY, Providence, R. I., reports that its cut-outs and fuses in the Manhattan Elevated Railway equipment have been so satisfactory that the company has received the contract for furnishing the entire fuse equipment for the Subway Rapid Transit Company, which is also a part of the Interborough Rapid Transit Company's system. It is stated that this order was also secured on merit, as the engineers of the subway division have been making further tests on their own account of these large capacity fuses, and the manufacturers were called upon to submit fuses as large as 800 amperes to be tested on a dead short-circuit.

THE NERNST LAMP COMPANY has recently obtained through its Philadelphia office, in charge of A. E. Baker, the contract for lighting Rocky Glen Park, Scranton, Pa., with 100 six-glower lamps. The Philadelphia office also recently secured the adoption of Nernst lamps by the Paxtung Electric Company, Harrisburg, Pa., and that company now has over 2300 glower units in service. The Denver Office of the Nernst Lamp Company, in charge of R. D. Marthens, lately received contracts for lighting the United States Army Post at Fort Logan, Colo., and several representative establishments in Cripple Creek, Colorado. In each instance, the Nernst lamps replace incandescent lamps.

COCHRANE HEATERS FOR STEAM TURBINE PLANTS.—It is interesting to note that the General Electric Company has selected Cochrane feed-water heaters for its plants at West Lynn, Mass., and Harrison, N. J., where Curtis steam turbines are to be installed. These heaters are to be rated at 3000 and 1000 horse-power, respectively, and will take the exhaust steam from the auxiliaries. Three 5000-h.p. Cochrane heaters also have been installed in connection with steam turbines at the Delway (Mich.) station of the Detroit Edison Company, and a 600-h.p. Cochrane feed-water heater will be used in the new turbine station of the Iowa & Illinois Interurban Railway Company, Clinton, Ia. A 2000-h.p. Cochrane heater which has been ordered by the Electric Company of America will be installed with steam turbines in the new plant at Marion, Ind.

ROGERS & STARR, general contractors and engineers, recently opened offices at 827 Perry Building, Philadelphia. The senior partner, Mr. H. A. Rogers, who is a graduate of Cornell University, was in past years connected with such representative concerns as the Baldwin Locomotive Works, Boston & Albany Railroad Company, Latrobe Steel Company and Ballinger & Perrot, the latter a leading Philadelphia firm of architects and engineers. Mr. B. H. Starr was previously connected with the Camden & Suburban Railroad Company (Pottstown, Pa.), superintendent of several telephone companies and supervising engineer for the Schuylkill Traction Company. The firm will engage in civil, mechanical and electrical engineering, the installation of power plants, etc., as well as the preparation of plans and specifications for all descriptions of mechanical and electrical engineering work.

THE NATIONAL BATTERY COMPANY, Buffalo, N. Y., is one of the most active builders of storage batteries in this country. The history of this establishment is unusual. It was originally part of the American Bicycle Company, which later became the Pope Manufacturing Company, and from them the entire capital stock has been purchased by individuals, who are, at the present time, not only extending the already large factory buildings, but so improving the interior arrangements that all the manufacturing methods and systems will be thoroughly up-to-date. Electric elevators, trolley car lines, etc., will equip the factory, carrying the heavy product handled rapidly from place to place. The chemical and electrical laboratories have been greatly increased in size, and are being equipped with the very latest types in every variety of instrument required for experimental work. The spirit of the new ownership and management is bold and aggressive, having at its command all the capital and resources that will be required to make the company a success, and it is pushing on as rapidly as it is possible to go. The largest product of the factory is batteries for power plants and various kinds of stationary work. After this the railroad and telephone batteries are the important product. For the manufacture of automobile storage batteries, separate departments have been made, so that as the volume of this work rises and falls, according to the season of the year, the factory output will be fairly well able to take care of the demand, and yet not interfere with the more continuous and larger volume of business in stationary power batteries.

CENTRAL STATION NEWS

ALABAMA.

JASPER.—The Jasper Water, Light & Power Company has been incorporated with a capital of $50,000, by Messrs. J. M. Cranford, L. W. Lollar, D. K. Carter and others.

JACKSON.—Mr. George F. Brockman, of this city, is erecting a large hydraulic electric light plant here. The plant, which will be operated on the direct-current system, is expected to be in operation about October 5.

DECATUR.—The city, it is said, purposes to establish an electric light plant. Heretofore Decatur has been supplied with current for lighting purposes from the plant of the Decatur Light, Power & Fuel Company, of New Decatur.

NEW DECATUR.—The following have been chosen as officers by the Decatur Light, Power & Fuel Company; Mr. H. S. Fleming, of New York City, president; Mr. J. J. Riordan, Jr., vice-president; Mr. H. B. Lovell, secretary; Mr. John Marston, treasurer, and Mr. Charles E. Mayer, superintendent.

MOBILE.—Messrs. J. A. Maloney, chief-engineer of the Mobile Light & Railway Company; S. H. Hinckley, chief engineer at the Mobile City Water Works, and A. J. Grove, engineer of the Mobile brewery, were influential in obtaining the passage recently of an ordinance for the inspection of stationary boilers, engines and elevators and the licensing of stationary engineers, which was passed by the City Council.

BIRMINGHAM.—At a special meeting of the stockholders of the Birmingham Railway, Light & Power Company held recently, it was decided to issue $10,000,000 worth of bonds protected by a mortgage. Part of the issue will be used to retire outstanding bonds, but the greater part will be utilized to carry out projected improvements and to complete those already under way. The company has also lately secured several large steam heating contracts.

CHEROKEE.—At a recent meeting of its stockholders, the Cherokee Development & Manufacturing Company, which is arranging to construct a large water-power plant on the Tallapoosa River for the transmission of electricity to Birmingham, voted to increase its capital stock from $50,000 to $100,000. The additional $50,000 is to be devoted to the purchase of an undivided half interest in the properties of the company from Sallie A. Jones, of Montgomery. The following officers were elected: President, Mr. Thomas H. Watts; secretary, Mr. J. Thorington; treasurer, Mr. James S. Pinckard; general manager, Mr. Henry C. Jones. Mr. Jones states that work on the plant will be begun at an early date.

ARKANSAS.

NORTH LITTLE ROCK.—The petition recently submitted to the council for the construction of an electric light plant and water works resulted in the passage of an ordinance providing for the establishment of such plants to be owned and operated by the city.

MAMMOTH SPRINGS.—The Mammoth Springs Electric Light Company is perfecting arrangements to increase its service by the addition of power and day circuits, for which purpose a new three-phase alternating-current generator is to be installed. The company is also contemplating the operation of a cotton gin and corn mill.

LEWISVILLE.—The plant of the Lewisville Light & Water Company, which was recently organized, has been completed and is now in operation. The company has been awarded the contract for the city lighting. The officers are as follows: President, Mr. F. R. Daniel; secretary and treasurer, Mr. G. W. Dobson; general manager and chief electrician, Mr. John W. Miller.

CALIFORNIA.

SEBASTAPOL.—Bids have been called for for a franchise to erect poles and wires for the transmission of electricity for light and power purposes in Sebastapol.

SACRAMENTO.—Mr. John Martin is now president of the Sacramento Electric, Gas & Railway Company, and Mr. John A. Britton is vice-president and manager.

FORTUNA.—The Humboldt Milling Company has applied for a franschise to erect and maintain a pole line for the purpose of extending its electric light system to various points in the valley, including Loleta, Fortuna, Rohnerville, Alton, Hydesville, Carlotta and Table Bluff.

ALTURAS.—A 400-h.p. lighting plant is being installed on Pine Creek, about seven miles from here. Current will also be supplied to commercial plants for operating purposes. The capacity may be increased as the demands require it, the water power being sufficient to generate 2500 horse-power.

REDDING.—The new power plant of the Northern California Power Company, situated on Cow Creek thirty miles from Redding and costing $200,000, is now in operation. As has been previously stated this plant was installed to supplement the one at Shingletown, the two plants having a combined capacity of 8000 horse-power and generating 44,000 volts.

LOS ANGELES.—This city is now amply supplied with electrical power from the Kern River. The largest single installment of power ever connected to the electrical system of the city is carried by a line which brings 10,000 horse-power from a source over 100 miles away. There are 758 miles of wire which weighs half a pound to the foot, making the entire weight of wire about 1000 tons. The wires are supported on the poles by 24,000 of the largest insulators ever used in California.

SAN FRANCISCO.—The San Francisco Gas & Electric Company has been directed by the Board of Supervisors to install forty new arc lamps in the southern part of the city. The work of renewing the city's street arc lighting system, at a cost of $50,000, will be carried on as rapidly as the Westinghouse Electric & Manufacturing Company can supply the new lamps, of which some 1500 have been ordered. These will be of the enclosed-arc type and each one will be hung on a bracket about four feet from the pole, so that there will be a minimum of shadow.

MONTEREY.—Articles of incorporation have been filed by the Vantana Power Company, fixing the capital stock at $500,000. Messrs. C. P. Bradford, of San Francisco; W. E. Bradford, of San Jose; F. L. Ordway and C. V. Hove, of Monterey; F. C. Richardson and C. M. Howard, of Pacific Grove, and H. S. Bradford, of Evergreen, are the directors. The company purposes building a large dam at the junction of Vanta Creek and the Big Sur River, 40 miles south of Monterey, where it is said that from 3000 to 5000 horse-power can be developed. The current generated by means of the water power will be transmitted to Monterey over a high-tension transmission line.

YREKA.—The Siskiyou Electric Power Company, which recently acquired the plant and business of the Aetna Electric Light Company, also controls the Ashland Electric Power & Light Company of Ashland, Ore. New machinery is to be installed soon in the power house of the company, consisting of a 750-kw. generator and a new water wheel. The current generated at the main plant is distributed through seven sub-stations located in Montagne, Yreka, Grand View and Etna, and at the Mt. Vernon and New York mines. Electricity for lighting purposes is supplied by the company to Etna, Fort Jones, Montagne and Greenview. The officers are as follows: President, J. Churchill; vice-president, J. W. Churchill; secretary, A. J. Roseborough; treasurer, J. P. Churchill; manager, E. H. Steele; superintendent and chief engineer, C. G. Steele; chief electrician, F. G. Robley.

RICHMOND.—The Richmond Light & Power Company, whose office is in the Crocker Building, San Francisco, has discontinued the use of its steam plant, having recently entered into a contract with the Bay Counties Power Company for the purchase of electric current for a term of ten years. The steam plant is maintained in good condition, however, and may be started up at any time should it be required. In order to connect the company's system to the lines of the Bay Counties Power Company it was necessary to install three 100-kw. and three 50-kw. 50,000/2200-volt transformers of General Electric make. The plant is now supplying a 24-hour service and is furnishing approximately 500 horse-power to 60-cycle, three-phase induction motors. The lighting load consists of 3500 16-c.p. lamps and 65 alternating-current arc lamps. The arc lamps supplied to the town of Richmond are paid for by public subscription, as the town has not yet been incorporated, the rate for same being $75 per year on the basis of a one o'clock every night schedule. The rate for commercial arcs is $6 per month per lamp burning until midnight and $9 per month for all-night service. All current is sold on the meter basis. The following are the present officers of the company. President, W. G. Henshaw; vice-president, W. A. Bissell; secretary and treasurer, C. W. Waller; manager, H. B. Kinney.

COLORADO.

GOLDEN.—The Golden Illuminating Company has recently installed at its plant a new 150-kw. generator direct-connected to a water wheel.

VICTOR.—The Pike's Peak Power Company has completed the construction of its hydraulic electric plant and has consolidated with the Pueblo Traction & Lighting Company. Mr. R. M. Jones, chief engineer and general superintendent of the former company, has severed his connection with that company and is now free to undertake other consulting engineering propositions.

CONNECTICUT.

NEW LONDON.—The Groton Water & Electric Company will increase its facilities at the power house and pumping station at Poquonoc by the installation of a 250-h.p. steam engine.

DELAWARE.

WILMINGTON.—The Susquehanna Light Company has been organized with a capital of $75,000.

NEW CASTLE.—New Castle is now supplied with light, current for which is generated at the plant of the Wilmington, New Castle & Southern Railway Company. The following are the officers of the company: H. L. Evans, president; Willard Saulsbury, vice-president; C. P. Holcomb, secretary and superintendent; F. R. Morrison, treasurer; M. K. Lancaster, chief engineer, and George Unger, chief electrician. Current is supplied to 35 2000-c.p. city arc lights and 800 16-c.p. commercial incandescent lights.

DISTRICT OF COLUMBIA.

WASHINGTON, D. C.—At the annual meeting of the stockholders of the International Motor & Power Company, held recently, the following trustees were elected: Hopewell H. Darnielle, Washington; Samuel W. Smith, M. C., Pontiac, Mich.; Charles F. Joy, St. Louis, Mo.; Senator Jacob H. Gallinger, of New Hampshire; Alexander H. Bell, Washington; William L. Walter, Port Huron, Mich.; Lieut. Commander Frank W. Bartlett, U. S. N.; Edgar Weeks, Mt. Clemens, Mich.; Bert H. Brockway, Washington; Maj. Henry L. Biscoe, Washington; Tomkins C. Delavan, New York City; Charles H. Fred, J. S. Ziegler, S. H. Bell and Francis Nye, of Washington.

In the District of Columbia the electrical regulations regarding the production, use and control of electricity have been passed upon by the corporation counsel and pronounced correct, with the suggestion that the regulations be advertised a month before going into effect.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

FLORIDA.

PENSACOLA.—The Pensacola Suburban Electric Company has been organized here by A. C. Berry, J. E. Wolf and others.

OCALA.—The citizens have voted for a bond issue of $45,000, a portion of which will be used in improving the electric light plant.

ST. AUGUSTINE.—Reports state that Mr. T. R. Osmond, of New York City, contemplates establishing an electric light plant at this point.

MIAMI.—The Miami Electric Light Department of the Florida East Coast Hotel Company successfully started its new city lighting plant a short time ago. Hitherto the city has been lighted from the company's plant in the Hotel Royal Palm. The new plant is operated on a 60-cycle two-phase 2300-volt system, the equipment consisting of two G. E. 100-kw. engine-type generators with Ball & Wood tandem compound condensing engines and Oil City boilers arranged to burn wood with mechanical draft.

TAMPA.—The Tampa Electric Company is now preparing to erect and install one of the largest electric power houses in the South. The plant will be located on the Hillsboro River, on the site now occupied by the temporary plant. The frame building housing the temporary plant will be removed and the brick structure erected in its place, covering considerably more ground than the present one. The plans for the new plant and building have already been prepared. The building will be 50x100 feet, and the new boilers and machinery will give a capacity of 1000 horse-power. Ground has been broken, and the company expects to have the new plant in use by November 1. During erection and installation, the temporary plant now on the ground will continue in use.

GEORGIA.

WRIGHTSVILLE.—The Wrightsville Electric Light Company has been organized here with Mr. A. T. Cobb as president.

DOUGLAS.—Bonds to the amount of $20,000 have been sold to provide for the construction of an electric light plant and water works.

BAINBRIDGE.—The citizens have voted in favor of purchasing the present electric light plant, for which purpose $20,000 bonds will be issued.

COLUMBUS.—Mr. H. A. Tibbs announces that he has severed his connection with the Columbus Power Company to take charge of the York Haven Water & Power Company's plant at York Haven, Pa.

GRIFFIN.—The citizens have voted for a bond issue of $100,000, of which $35,000 will be expended in improving and extending the electric light system and water works, for which plans and specifications are being prepared.

GRIFFIN.—The stockholders of the Flint River Power Company have organized with W. J. Kincaid, president, and J. P. Nichols, secretary. The company has a cash capital of $25,000, with the privilege of increasing it to $500,000, and will in the near future construct an electric power plant at Flat Shoals.

MOULTRIE.—Mr. Guy P. Felton, who has been superintendent of the Moultrie Electric Light & Water Works for the past three years, has resigned that position to accept a similar place at Blakely. He has been succeeded here by Mr. M. A. Barr, of Columbus, who assumed the duties of his new position August 15.

THOMSON.—Bids have been received for furnishing material and constructing an electric light plant, consisting of a brick power house; a 66-in. x 16-ft. high-pressure boiler, heater and feed pump; one 135-h.p. engine, one 90-kw. alternator and station apparatus, six arc lamps, 36 50-c.p. series incandescent lamps, 800 lights capacity in transformers, wire, poles, lines, etc.

GAINESVILLE.—A short time ago fire destroyed the warehouse of the North Georgia Electric Company, entailing a loss of $20,000 with no insurance. In the building were stored part of the machinery for the Chattahoochee power house and parts of the merry-go-round being erected at the park, together with a number of barrels of cement. The loss will delay the utilization of the new power house, as considerable time will be required to secure new machinery.

IDAHO.

AMERICAN FALLS.—The three general electric companies operating here have been consolidated under the name of the Idaho Consolidated Power Company.

MONTPELIER.—The Montpelier Electric Light Company has in course of construction a new 750-h.p. water-power plant. Mr. J. R. Brennan is president; D. Orr Paynter, vice-president; J. A. Rostan, secretary and manager, and J. F. Perkins, chief electrician.

BOISE.—The Electric Power Company, Ltd., is now supplying current for 40 2000-c.p. arc commercial lights and 4000 16-c.p. incandescent lights, and is also operating a day circuit, supplying current for power purposes at 110 volts. Mr. Harry D. Pope is manager and superintendent of the plant.

PECK.—Mr. Lakin, the owner of the mill here, has submitted two propositions to the business men of the town. The first is that if the town is incorporated he will put in an electric light plant and contract with the town for furnishing lights; or if the town prefers to own its plant he will furnish the power for operating the same at cheap rates.

ILLINOIS.

ONEIDA.—The Onedia Light & Power Company is installing meters and in the future all current will be charged at meter rates.

DE KALB.—It is said that a new power plant is being installed here by Mr. J. Haisch, which will furnish lights for the town.

GENESEO.—The Geneseo Electric Light Company has just closed a five-year contract with the city authorities to supply the lighting current for the town.

SAYBROOK.—The Saybrook Electric Light, Heat & Power Company has filed articles of incorporation, fixing its capital stock at $10,000. Mr. E. E. Sayler is among the directors.

ROCKFORD.—At a meeting of the stockholders of the Central Heat & Power Company, it was decided to expend about $30,000 for additional machinery, the improvements to be made at once.

HOMER.—The plant of the Homer Light & Power Company has recently changed hands, it having been purchased by W. S. Thomson, of Fithian, and G. C. Browen for a consideration of $8000.

ALPHA.—Improvements are under way at the plant of the Alpha Electric Light & Power Company, whereby it will be enabled to extend its service to Rio, Knox County, this fall, and possibly to Mola and North Henderson in Mercer County.

PEORIA.—The council has advertised for bids for furnishing 675 electric street lights of not less than 2000 candle-power for two years from November 1 on an all-night schedule for every night, also for 32-c.p. incandescent lights for alley lighting.

CHICAGO.—The Illinois Heating & Light Company has been granted a charter to establish a heat, light and power plant. Messrs. E. T. Noble, C. E. Moore and J. S. Huey are among the organizers of the company, which has a capital stock of $15,000.

KEITHSBURG.—The plant and business of the Keithsburg Electric Light & Power Companw have been acquired by A. L. and O. B. Hayden. The new owners, it is said, contemplate making changes in the plant and equipment which will greatly improve it.

EDINBURG.—Articles of incorporation have been filed by Messrs. J. R. Harrington, L. E. Swigert and Reuben Wilkinson for the Edinburg Light, Heat & Power Company. The company's capital stock is $30,000 and its purpose is to operate a light, heat, power and water plant in this city.

CHICAGO.—Fifteen hundred new arc lamps will be installed on 30 miles of streets of the Northwest Side, Chicago, when the new electric lighting station planned by city electrician Ellicott at Fullerton Avenue and the North Branch of the Chicago River is completed. This will be one of the first results of the bond issue for permanent improvements. The station will cost $100,000 and Mr. Elliott expects to have it completed by January 1.

GRANITE CITY.—The city authorities are desirous of having some responsible company locate here for the purpose of putting up and operating a modern electric light and power plant. A plant would be required capable of supplying 150 arc lights and 5000 incandescent lights, having also a sufficient capacity to furnish current to the various industries of the city demanding power. Mr. Fred A. Eisele, of the City Light Committee, states that the town is one of the best in the State and he considers the opportunity an excellent one for the right parties.

INDIANA.

ELKHART.—The Conn Electric Company is making arrangements to extend its electric light service to Goshen.

MARION.—A 2000-h.p. Cochrane heater has been ordered by the Electric Company of America to be installed with steam turbines at its new plant in this city.

ALEXANDRIA.—A contract has been awarded by the City Council to the Alexandria Electric Light & Power Company for lighting the city streets for a period of ten years.

SHELBYVILLE.—Mr. N. B. Stabley has petitioned the Board of County Commissioners for a franchise permitting him to erect poles and string wires for supplying current for lighting purposes.

SOUTH BEND.—The Economy Electric Corporation has been organized with a capital stock of $10,000. The directors are named as follows: Ulysses S. Meeks, Cora M. Meeks, William F. Wood and Blanche D. Wood.

VINCENNES.—Various improvements are under way at the power plant of the City Electric Lighting Company, which include the installation of new boilers, engine and dynamos and the extension of the incandescent feeders and arc circuits.

RICHMOND.—Mr. S. A. Gard, superintendent of the municipal electric light plant since it was put in operation two years ago, has resigned his position and left the city. Mr. Charles Rodgers has been appointed as his successor. After the city's contract with the Light, Heat & Power Company expires in September, the streets will be lighted by current from the municipal plant, the council having rejected the company's proposition to light the city at $60 per lamp per year.

FORT WAYNE.—The syndicate of capitalists which recently purchased the Jenney Electric Light & Power Company, merging it with the Fort Wayne Electric Light & Power Company, at a meeting held recently, elected E. C. Werner, of New York, president, to succeed H. P. Bondhight; J. W. White, vice-president; treasurer, F. S. Hunting; secretary and manager, C. G. Guild. The company expects eventually to secure control of the entire electric light and power business of Fort Wayne, that city's traction lines and all of the interurban lines centering there, in addition to a large interest in the Indianapolis Traction & Terminal Company, the Union Traction Company, of Indiana, and the Fort Wayne & Wabash Valley Company. The new company, it is said, will erect an enormous power house capable of lighting the city and of furnishing power for the city and park and the interurban lines. The company controls a franchise for steam and hot-water heating and the exhaust from the power house will be utilized in this way.

INDIAN TERRITORY.

WILBURTON.—The contract for constructing the proposed $50,000 electric light plant for this place has been awarded to James Dignan.

PAULS VALLEY.—The electric light plant of Thompson Brothers, which was destroyed by fire a few weeks ago, will be replaced by a new plant which will be built at once.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

IOWA.

LAMONI.—It is understood that Mr. M. L. Burt, of Bedford, Ia., is negotiating for the purchase of the electric light plant here.

GREENE.—Reports state that a company has been organized to purchase and operate the electric light plant, now owned by Mr. F. J. Pfiffner.

LAKE CITY.—The Lake City Electric Company's plant, which is controlled by local capital, has been leased for a term of years to Otto E. Brownell.

WILTON JUNCTION.—Plans have been prepared by Mr. G. W. Bissell, of Ames, Ia., for the improvements to be made to the village electric light plant, for which $5250 bonds were recently issued.

BOONE.—The proposition for municipal ownership of the electric lighting plant, which has been so vigorously agitated of late, was defeated at the recent election. The council has awarded the contract for the city lighting for a period of five years to the Boone Electric Light & Street Railway Company at the rate of $62.50 per light per year for 80 lights of 1200-c.p. each.

WAUKON.—The Waukon Electric Light Company, in connection with the Decorah Electric Light Company, of Decorah, Winneshiek County, is preparing plans for a water power plant to be constructed on the upper Iowa River about 12 miles from Decorah to supply power to the two towns and adjacent territory. Construction work will begin as soon as the proposition can be financed.

KANSAS.

EMPORIA.—Mr. W. O. Johnson, of Winfield, proposes to establish a $20,000 electric plant in this city.

MANHATTAN.—C. P. Dewey, of Chicago, president of the Manhattan Ice, Light & Power Company, of this city, died recently.

OSKALOOSA.—The power and lighting plant of the Oskaloosa Electric Light Company is in charge of Mr. J. S. Buck as manager.

CONCORDIA.—The Home Light & Power Company has been chartered to build and operate electric light and power plants, with a capital of $50,000.

NESS CITY.—The Ness City Electric Light Company has been organized by Messrs. C. H. Brassfield and A. S. Foulks. The company has secured the city lighting contract and is operating its light plant by means of power supplied by the Ness City Milling Company. It is the company's purpose, however, to install its own power plant in the near future, to be run in connection with an ice plant. Mr. Foulks is secretary and treasurer, Mr. Brassfield is manager and superintendent, and Mr. B. Hawkins is chief engineer and electrician.

KENTUCKY.

FULTON.—The Fulton Electric Light & Power Company is adding a 150-h.p. boiler to its plant equipment.

DANVILLE.—The council has advertised for bids for the purchase of a twenty-year franchise to construct, maintain and operate an electric lighting and power plant in the city. The purchaser of said franchise shall also have the right to construct, operate and maintain an electric railway throughout the city.

HOPKINSVILLE.—The Hopkinsville Gas Light & Power Company has been reorganized under the name of the Hopkinsville Gas & Electric Company and articles of incorporation filed by Messrs. W. T. Tandy and James A. Young, Jr., of this city, and W. H. White, of Cadiz. The capital stock is $25,000. It is presumed that the plant will be rebuilt with as little delay as possible.

LOUISIANA.

LAFAYETTE.—The City Council has awarded a contract to the Standard Electric Company, of New Orleans, for two dynamos of 1500 lights capacity each and one 250-h.p. engine to be installed in the city plant.

ABBEVILLE.—The Abbeville Light, Power & Water Works Company has in preparation plans for installing a 15-ton ice plant. Heavier mains will be put in than those now in use, and a generator set is to be added to the equipment of the power plant.

NEW ORLEANS.—The Consumers' Electric Light & Power Company will, it is announced, shortly commence the work of erecting its plant. The company is backed by retail merchants of this city, all of whom are subscribers to the stock and will utilize the power developed.

PROVIDENCE.—The town proposes to issue bonds for a water and electric light plant.

MAINE.

PORTLAND.—The stockholders of the Rumford Falls Power Company, of this city, have voted to increase the amount of its capital stock from $500,000 to $800,000.

BRUNSWICK.—Low water in the Androscoggin River recently necessitated a shutdown for a few hours at the plant of the Brunswick Electric Light & Power Company. Other plants depending upon the water power were obliged to suspend operations temporarily.

SOUTH WINDHAM.—Considerable damage was done by lightning recently to the plant of the Mallison Falls Power Company at Mallison Falls, near this city. The dynamos, switchboards, lightning arresters and other pieces of apparatus were considerably damaged and it was several days before the plant could be put in shape for work. The plant furnishes power to several industrial concerns and also supplies current to the Portland Railroad Company for the operation of its cars from Westbrook to South Windham.

MARYLAND.

FREDERICK.—Extensive improvements are about to be made to the electric light plant of the Frederick Gas & Electric Company. The company has purchased two new dynamos, two engines, one of which is a 200-h.p. Corliss engine, a large amount of copper wire and other materials for reconstructing its lighting system.

MT. WASHINGTON.—The county commissioners have closed a contract with the Mount Washington Electric Light & Power Company for furnishing electric lights for public highways at Mount Washington, Arlington, Govanstown, Towson, Lutherville, Pikesville, Glyndon and Riderstown. The contract is for five years, and the company is allowed $35 per year for lights of 60 candle-power and $25 per year for 32 candle-power lights, to be kept burning on nights when the moon is not shining. The company is allowed $42 per year for lights of 60 candle-power and $36 per year for lights of 32 candle-power, to be burned all night.

MASSACHUSETTS.

HUDSON.—The municipal light and power plant will furnish electricity for motive power after September 1.

HAVERHILL.—A 300-h.p. engine has been installed in the Charlesworth power plant which furnishes current for nearly all the factories on Washington Street.

PITTSFIELD.—E. P. Stearns, of Boston, is preparing plans for a power plant to be situated on the Housatonic River at Pittsfield. A stock company is being formed with a capital of $500,000.

NEWTON.—The Newton & Watertown Gas Light Company, which is controlled by the Edison Electric Illuminating Company of Boston, will discontinue the operation of its generating plant and will obtain electricity from the Edison Company.

BOSTON.—Mr. Charles L. Edgar, president of the Edison Electric Illuminating Company of Boston, was recently presented a fine bronze bust of Edison by his employes, associates and friends. The bust stands on a pedestal, the total height being 6 ft. 3 ins.

BEVERLY.—The Beverly Gas & Electric Company has been making additions to its already well-equipped station. Three new 150-kw. alternating-current generators and a new marble switchboard are among the improvements, and the company is now furnishing a twenty-four-hour service, lighting Manchester-by-the-Sea in addition to Beverly.

LEOMINSTER.—Mr. Benjamin F. Peach, of Lynn, Mass., at a recent meeting of the stockholders was chosen clerk of the Leominster Electric Light & Power Company to succeed the late Dr. C. A. Wheeler. Mr. Peach is also a director of the corporation.

TURNERS FALLS.—The Franklin Electric Light Company elected the following officers at its annual meeting: President, J. F. Bartlett; secretary, E. I. Cassidy; treasurer, W. C. D. Thomas. The board of directors is composed of Messrs. Porter Farwell, C. W. Hazleton, H. D. Bardwell, W. D. Russell. Within the next year the company expects to be able to obtain power from the Turners Falls Company and will then be in position to greatly extend its system in the village.

MICHIGAN.

PLAINWELL.—The Brownell Electric Company has been granted the village lighting contract.

COLDWATER.—Mr. A. L. Pond has been reelected superintendent of the water works and electric light plant at this place.

PLAINWELL.—A new company has been formed here, known as the Easley Light & Power Company, with a capital stock of $30,000.

BAY CITY.—Bonds to the amount of $49,500 have been issued by the Electric Light Department for electric light improvements to enable the city to establish a commercial plant.

IONIA CITY.—The lighting contract between the city and the Ionia Electric Company expires in October, and bids are being advertised for preparatory to making a new contract.

ESCANABA.—It is understood that the city of Escanaba is likely to discontinue its municipal lighting business, as its operation of the electric light plant has not been a financial success, it is said.

DETROIT.—The new 800-h.p. engine recently installed in the power house of the City Electric Light Plant has been put in operation. The engine-generator unit developed under test a capacity of 570 kilowatts.

ST. IGNACE.—The city authorities have issued $15,000 bonds for the installation of an electric light plant to take the place of the one recently destroyed by fire, and is now in the market for a complete incandescent plant.

ALPENA.—The sale of the $250,000 water and electric light bonds made on June 25 has been declared off. The bonds have been readvertised and as soon as the bids have been received and opened the contracts will be awarded.

PONTIAC.—The old arrangement of lighting the streets only on dark nights has been discontinued, and a ten-year contract for lighting the city every night has been awarded to Mr. J. C. Hoffman, of Detroit, at the rate of $57.30 per light per year.

DETROIT.—Mr. Frank Hellen, of the Detroit City Gas Company, recently resigned his position as superintendent of distribution to accept a responsible position in Rochester, N. Y., with the gas, railway and electric lighting company of that city. On leaving the Detroit Company he was presented with a diamond by about fifty of his associates.

LANSING.—Improvements to cost $20,000 are to be made to the city lighting system and plant, and the following contracts have been awarded for machinery: To the Buckeye Engine Company for a 600-h.p. engine, the Bullock Electric Manufacturing Company for a 425-kw. generator, and the George F. Blake Manufacturing Company for a condenser.

MANISTIQUE.—The Manistique Light & Power Company has in preparation plans for extensive improvements. These include a new building for its plant, which is to be materially enlarged in order to meet the demand for power of new industries now locating in this city. It is estimated that about $50,000 will be spent for the purpose. The energy utilized is obtained from the river, which is harnessed near the point at which it empties into Lake Michigan.

LYONS.—Mr. H. R. Wager is at work rebuilding the plant which was ruined by the flood last winter at Wagar's dam, the channel of the river being changed so that there is no water within

25 feet of the dam. The power house will be located on the south bank of the present river, about 200 feet south of the old one. The dam will be extended 150 feet, giving it a total length of 350 feet, and every precaution will be taken to make it flood-proof. The capacity of the plant will be materially increased, the cost of rebuilding it being estimated at $50,000.

NEGAUNEE.—The new electrical apparatus for the municipal lighting station has been installed and the efficiency of the plant has been increased. The two small generators have been displaced by a 200-kw. generator capable of supplying both the lighting and power circuits with current. Other machinery installed includes a 250-h.p. engine, a condenser, heater and duplex pump, besides several smaller pieces. Superintendent T. E. Gaffney has also made various improvements in the lighting circuits, including the installation of new enclosed arc lamps. Another improvement is embodied in the division of the city into two sections, which arrangement, together with separate transformers, gives independent service for each section of the city. A new switchboard has been put in, and No. 2 wire has been substituted for Nos. 6 and 8 in the secondary leads.

MINNESOTA.

VIRGINIA.—It is stated that the Virginia Light & Water Company has arranged to sell its plant to the city.

ROYALTON.—The citizens of Royalton have voted an issue of $10,000 bonds for the erection of a lighting plant.

CASS LAKE.—The new plant of the Cass Water, Light & Power Company has been completed and is in operation.

HIBBING.—Mr. O. P. Finnes has succeeded Mr. J. B. Leary as superintendent of the municipal light and water plant.

SPRING VALLEY.—Plans and specifications for a municipal lighting plant to cost about $10,000 have been adopted by the city authorities.

JORDAN.—The Jordan Electric Light & Heating Company contemplates installing a storage battery and a day circuit for power purposes.

LAKEFIELD.—Mr. Frank Burbank has resigned as superintendent of the Lakefield electric light plant, to accept a similar position at St. James, this state.

WINONA.—The Winona Railway & Light Company will issue bonds to the amount of $400,000 with which to refund its old indebtedness and improve and extend its present system.

MANKATO.—The Mankato Railway, Light & Power Company, recently organized, has been granted a franchise for the operation and maintenance of a light and power plant and an electric railway system.

MISSISSIPPI.

BILOXI.—The Biloxi Electric Railway & Power Company is making the neecssary changes in its plant to enable it to operate a day circuit.

NEW ALBANY.—The citizens have voted to issue $20,000 bonds for the establishment of an electric light plant and water works system.

MAGNOLIA.—The Magnolia Electric Light Company is planning to install a new 150-kw. alternator and engine in its plant. The officers of the company are as follows: President, J. H. Pine; vice-president, Samuel Abram; secretary and treasurer, E. D. Reid; manager and superintendent, Xavier A. Kramer; chief engineer, J. Wall; chief electrician, S. P. Curlette.

MISSOURI.

AURORA.—The Aurora Light, Ice & Storage Company is arranging to introduce series alternating street arc lighting.

JOPLIN.—The proposition to bond the town for $30,000 to increase the capacity of the municipal electric plant has been carried.

LA PLATA.—The La Plata Electric Light Company is arranging to install a new engine and generator which will enable it to increase its service from midnight to all night. The company also lights Moulton, La.

COLUMBIA.—The city has purchased the property of the Columbia Water & Light Company for $67,000. The property consists of water works and an electric light plant. It will be controlled by a Board of Public Works composed of four members, appointed by Mayor Niedermeyer, as

LEXINGTON.—The Lexington Gas & Electric Company has in contemplation improvements which mean practically the reconstruction of its entire system. The town is to be rewired throughout and new enclosed arc lights installed. At the power house the old equipment is to be replaced by new engines and dynamos, new transformers and new meters.

MONTANA.

GREAT FALLS.—The Swift Current Oil, Land & Power Company, of this city, expects soon to commence operations in Teton County. The company is capitalized at $2,000,000 and a large amount will be spent in extensions and improvements in the immediate future.

NEBRASKA.

OMAHA.—The Bennett Company has been organized here with a capital of $80,000 for the purpose of acquiring light, heat and power plants.

SHELBY.—Mr. G. P. Safstrom, proprietor of the electric light plant here, is preparing plans to extend his circuits and is considering a change in voltage, current now being generated at 130 volts.

VALENTINE.—The electric light plant of this place is run in conjunction with the Minnechadusa Mill and is owned by Mr. S. F. Gilman. Mr. C. S. Gould is manager of the plant and Mr. J. L. Hewitt, chief electrician. Current is supplied to 9 city arc lights, 18 commercial arc lights and 800 commercial incandescent lights, on an all-night schedule.

NEVADA.

RENO.—The Electric Light Company is reported incorporated, with a capital of $50,000, by G. H. Taylor, C. E. Horton and others. The principal place of business will be in Reno.

NEW HAMPSHIRE.

MILFORD.—In rebuilding the dam of the Milford Electric Light Company, which was damaged by the spring floods, the "crib" style was used, it being claimed that it would better withstand the ravages of the ice. The timber is green white pine, the open space in the dam being filled with stones and boarded over at the top.

NEW JERSEY.

WASHINGTON.—The Washington Electric Light Company is considering adding a day circuit to its service,.

NEWARK.—The Inter Gas & Power Company has been incorporated with a capital stock of $1,000,000. F. W. Hatch and G. D. Russell are among the directors.

JERSEY CITY.—The Burke Electric Company has filed articles of incorporation, showing a capital stock of $50,000. James Burke, Francis E. Drake and Paul Wilcox are the incorporators.

CAMDEN.—The Monterey Electric Street Railway, Light & Power Company has filed articles of incorporation stating its capital stock to be $225,000. T. H. Beckett and E. F. Walker, with others, form the board of directors.

METUCHEN.—The Metuchen plant of the Public Service Corporation is being enlarged and two 500-kw. G. E. generators direct-connected to Curtis turbines have been contracted for. The installation is expected to be in running operation by the first of October. The lighting and power plant of the company at Plainfield will then be discontinued and converted into a sub-station.

NUTLEY.—A contract has been made by the Council with the Public Service Corporation, whereby the company is to provide 238 25-c.p. incandescent street lights at $16 per lamp. The contract is for one year, with the privilege of renewal for five years. The town has heretofore paid $14 per 32-c.p. light, with free lamps in council rooms, schools, fire houses and in front of each church. In addition to raising the price per lamp and reducing the candle-power, all free lights have been abolished by the Public Service Corporation.

NEW MEXICO.

CARLSBAD.—The Public Utilities Company has been organized here with a capital stock of $100,000 for the purpose of acquiring, installing, owning and operating telephones, telegraph lines, etc., and to acquire, construct and maintain a dam for the production of water-power which shall be used to generate electrical energy for electric light systems. The incorporators of the company are William A. Finley, Matthew S. Grooves, William J. Barber, J. O. Cameron and Dr. Fred F. Doepp.

NEW YORK.

DUNKIRK.—Mr. James Larson is now chief engineer of the Dunkirk Power & Heating Company.

WATKINS.—Bonds to the amount of $20,000 have been sold for the construction of the municipal electric plant.

CANAJOHARIE.—The plant of the Montgomery County Electric Light & Power Company has been destroyed by fire.

CORNING.—A new 250-kw. alternating-current generator is being installed in the plant of the Corning Gas & Electric Company.

FULTON.—The Fulton Light, Heat & Power Company is making arrangements for improvements to its water power system.

WARWICK.—Mr. Emil Geppet has succeeded Mr. J. Vanderhoff as chief engineer of the Warwick Valley Light & Power Company.

DUNDEE.—Mr. Edward L. Bailey, proprietor of the electric light plant of this place, is perfecting plans for pumping his water supply.

DESPATCH.—Messrs. A. H. Bown, W. W. Bown and W. P. Thistlewaite are named as directors of the Despatch Heat, Light & Power Company in the articles of incorporation recently filed by that company. The capital stock is fixed at $500,000.

PLATTSBURG.—Articles of incorporation have been filed for the Lozier Light & Power Company by E. R. Lozier, H. A. Lozier, Jr., and Samuel Regan.

FULTON.—It is stated that the Fulton Light, Heat & Power Company has accepted a contract offered by the board of public works to furnish the city with lights at $75 each.

BROOKLYN.—Commissioner Oakley, of the Department of Water Supply, Gas and Electricity, has been directed to have the overhead feed wires in numerous streets in the borough placed underground.

LOCKPORT.—The American District Steam Company has petitioned the Council for a franchise to install a system for supplying electricity for light, heat, power and refrigerating purposes in this city.

NEW YORK CITY.—The Knickerbocker Light & Heat Company of New York has filed articles of incorporation, placing the capital at $550,000 and naming the following directors: F. P. Billmeyer, H. R. Brayton and H. S. Fairchild.

KEYPORT.—The Middlesex & Monmouth Electric Light, Heat & Power Company and Jersey Central Traction Company have elected the following officers: President, Julius Christensen; treasurer, J. H. Morris; manager, F. D. Low; superintendent, Samuel Haigh.

MECHANICSVILLE.—The stockholders of the Halfmoon Light, Heat & Power Company recently elected the following directors: John C. Duncan, H. O. Bailey, William L. Howland, E. H. Strong, S. Nelson Lee, Stephen Lee, A. J. Harvey, Fred H. Ferris, Thomas Slavin, Dr. George Hudson and W. R. Palmer.

BUFFALO.—The Russell Power & Manufacturing Company, which has the same directors as the Central Power & Manufacturing Company, organized to furnish electricity in Albany and other eastern New York counties, has been incorporated with a capital of $20,000 and will extend its operations to several western counties of the State.

MOHAWK.—The high-tension wires of the Herkimer County Light & Power Company, which are to furnish light for this village, are to run along the tow-path from Little Falls to the village. The work has been commenced and ex-Canal Superintendent Wallace has been appointed state inspector of the work.

CATTARAUGUS.—The following are the present officers of the Cattaraugus Electric Light & Power Company: S. F. Binger, president; O. J. Setter, vice-president; H. B. Easton, secretary,

treasurer and purchasing agent; F. Crawford, manager and superintendent; George W. Barton, chief engineer and electrician.

ROSLYN.—The Nassau Light & Power Company, which is a consolidation of the Roslyn Light & Power Company, Franklin Electric Ice Company, North Hempstead Light & Power Company and the municipal plant of the village of Hempstead, has in course of construction a new sub-station on the tide water at Glenwood, Long Island.

COHOES.—The annual meeting of the stockholders of the Mechanicsville Electric Light Company was held recently, when the following directors were elected: James Greenaway, M. F. Farron and Edwin Farron. The directors elected these officers: President and treasurer, Edwin Farron; vice-president, James Greenaway; secretary, M. F. Farron.

GENEVA.—Plans are under way for the consolidation of the electric light plants of Auburn, Waterloo, Seneca Falls and this city. The electric power and lighting plants in this city, Waterloo and Seneca Falls are already under the management of one company, the Geneva Power & Light Company, and it is said the plans also contemplate the acquiring of the Auburn plant.

NIAGARA FALLS.—The control of the Niagara Falls Gas & Electric Light Company is said to have passed into the hands of Canadian capitalists. The company has been reorganized and the following officers elected: President, F. A. Dudley, Niagara Falls; vice-president and treasurer, Frederic Nicholls, Toronto; temporary secretary, Harry Highland, Niagara Falls.

TAUGHANNOCK.—The new power plant being built by the Ulysses Electric Light & Power Company at Taughannock Falls, under the direction of Mr. Gardner S. Williams, is rapidly approaching completion and the work is being pushed with the utmost vigor. With this new source of power it is expected to furnish electric service to the towns of Trumansburg, Jacksonville, Taughannock, Interlaken and all intervening points.

NIAGARA FALLS.—The Niagara Falls Power Company is building a new 24-duct conduit from the New York end of the upper steel arch bridge in Niagara Falls up Niagara Street to Fourteenth Street and thence to its power stations. In this conduit will be placed the cables that will connect the plant of the Canadian Niagara Power Company with the generating stations of the Niagara Falls Power Company, thus ensuring a continuous-current service to the patrons of both companies.

LOCKPORT.—The directors of the Niagara, Lockport & Ontario Power Company are stated to have voted to authorize the issue of a mortgage of $24,000,000 upon the company's corporate property to secure a like issue of bonds. This is preliminary to the construction of the Lockport power canal. Rights of way and options on property have been secured, and the company proposes to establish its plant, for the purpose of supplying electric power over as wide a radius as possible. The company will now transmit electricity as far east as Utica and as far south as Pennsylvania.

ALBANY.—The Gentral Power & Manufacturing Company, of this city, has filed a certificate of incorporation. The company proposes to manufacture electricity for light, heat and power purposes. The capital stock is $10,000, and the directors are Charles R. Huntley, William R. Huntley and D. T. Nash, all of Buffalo. The company will operate in the counties of Schenectady, Saratoga, Albany and Rensselaer, the cities of Schenectady, Cohoes, Watervliet, Troy and Albany and the towns of Glenville, Rotterdam and Niskyuna, Schenectady county; Clifton Park, Half Moon, and Waterford, Saratoga County; North Greenbush, Rensselaer County.

LOCKPORT.—The Niagara County Irrigation & Water Supply Company is stated to have filed in the County Clerk's office at Lockport a map of a canal, the route of which is from La Salle, where it takes in the water of Niagara River, directly and also through Cayuga Creek, in a northwesterly direction, nearly parallel with the Military Road to Pletcher's Corners at the northeast corner of the city of Niagara Falls, along Bloody Run, to the bank of Niagara River, just above Devil's Hole, where there is a sheer drop of 300 ft. It is proposed to erect a power house and plant at the Devil's Hole, capable of generating 150,000 horse-power. The canal will be 120 feet wide and carry 18 feet of water from the intake to Pletcher's Corners, and from there to the Devil's Hole it will be 60 feet wide and 18 feet deep. The contract for the construction work of the canal has been awarded to the Frontier Construction Company of New York. The enterprise is said to involve an expenditure of $10,000,000.

NORTH CAROLINA.

RALEIGH.—The Raleigh Electric Company is considering some much needed extensions in the city.

KINSTON.—Mr. J. A. Harvey is superintendent of the municipal electric lighting plant of this city.

LUMBERTON.—The town now operates its own electric light plant, which is in charge of Mr. E. G. Couch, superintendent.

ROPER.—The electric plant operated by the Blount Milling Company has been sold to Mr. George W. Roper, of Norfolk, Va.

SOUTHERN PINES.—The R. L. Chandler Electric Light Plant, which furnishes light to the towns of Troy and Biscoe and whose office is in this city, is considering installing a small auxiliary steam plant shortly. Orders have been placed for the boiler and engine.

RAEFORD.—A charter has been granted to the Raeford Power & Manufacturing Company, with a capital of $200,000. The stockholders are J. W. McLaughlin, T. B. Upchurch and John Blue. The company will develop water and electric power and operate textile plants.

ASHEVILLE.—The W. T. Weaver Power Company has ordered a three-phase, alternating-current generator of normal 1200 horse-power capacity to be delivered by October 15. This will double the capacity of the present plant. President Weaver considers that the French Broad River, on which the plant is located, is one of the best streams in the country for generating power on account of the uniformity of the flow.

GRAHAM.—The town authorities have decided to replace the present street lights and water tanks by an up-to-date system of electric lights and water works. They have contracted with the Southern Service Corporation, of Washington, D. C., to have put up 20 or more arc lights, aggregating 40,000 candle-power, and 30 fire hydrants for the town, at a cost of $2400 a year. Private parties will be supplied at proportionate rates.

NORTH DAKOTA.

LARIMORE.—Mr. E. L. Ross has resigned his position as superintendent of the Larimore electric light plant.

LAMOURE.—The city is considering the advisability of constructing an electric light plant to be operated by the town.

RUGBY.—Mr. L. W. Cornelius has resigned his position as superintendent of the lighting plant of this city, which has been sold to John Kain, of Devils Lake.

GRAND FORKS.—The Grand Forks Gas & Electric Company has recently made about $20,000 worth of improvements, having enlarged its plant which is now housed in a new building and installed an almost entire new equipment of machinery.

OHIO.

ST. PARIS.—Mr. M. N. Beymer is in charge of the municipal lighting plant as superintendent.

TOLEDO.—Mr. E. B. Yanyan is now superintendent of the Toledo Heating & Lighting Company.

SHELBY.—The voters of Shelby have defeated the proposition to raise $10,000 additional to rebuild the electric light plant.

STEUBENVILLE.—The Steubenville Iron Works contemplate installing a new 800-kw. engine-generator unit in its electric plant.

TOLEDO.—The contract for building an addition to the power house of the Toledo Railways & Light Company has been awarded Bentley & Sons at $30,000.

HILLSBORO.—The Hillsboro Light & Fuel Company has increased its capital stock from $40,000 to $52,000. Mr. I. McD. Smith is president of the company.

BUCYRUS.—Reports are to the effect that the Bucyrus Gas & Electric Light Company has passed into the possession of James Finley, of Pontiac, Mich., in consideration of $100,000.

BELLEVUE.—The proposition to bond the city for $40,000 for the construction of an electric light plant was defeated at a recent election of the citizens. It is probable that the contract with the Bellevue Light & Power Company will be renewed.

BELLEVUE.—Mr. G. Cathcart has succeeded Mr. C. M. Lewis as superintendent of the Bellevue Light & Power Company. The company reports a healthy increase of patrons on its residential and commercial lighting circuits and contemplates adding a day load.

VERSAILLES.—The municipal electric lighting plant is in the market for about 500 feet of insulated wire and one, possibly two, direct-connected generators for the power house; also a vacuum pump for the water works. Mr. A. E. Waymire is superintendent and chief engineer and electrician.

HARRISON.—J. P. Hornaday & Co., of Cincinnati, have purchased for Cincinnati and Cleveland (Ohio) capitalists the water works and electric light plant of this city. The Harrison Light & Water Company completely controls all the public utilities of Harrison, both on the Indiana and Ohio sides of the line.

SEBRING.—The City Light & Power Company proposes to increase the capacity of its plant shortly. The company's officers are as follows: President, George E. Sebring; vice-president, E. H. Sebring; secretary and treasurer, W. H. Sebring; manager, Fred Sebring; superintendent, W. M. Murphy; chief electrician, S. E. McKee.

NEWARK.—W. G. Taafel, general manager of the Citizens' Electric Light & Power Company of this city, recently committed suicide by throwing himself in the Licking River. He was receiver for the Newark Savings Bank and became despondent because of financial matters. He left a note saying he was innocent of any wrong-doing in connection with the bank. Mr. Taafel was at one time a machinist, but at the time of his death was one of the leading business men of the town.

OKLAHOMA TERRITORY.

TONKAWA.—It is reported that an electric lighting plant may be established at this place.

KINGFISHER.—Mr. J. L. Bowers is superintendent and chief engineer and electrician of the municipal lighting plant.

OKLAHOMA CITY.—A charter for twenty years has been issued to the Le Clair Electric Company, composed of L. A. Le Clair, B. F. Leggett and Charles Edward Johnson. The company's capital stock is $10,000 and its principal place of business will be in this city.

OREGON.

PHILOMATH.—Mr. A. Horning is making arrangements to construct an electric light plant here in the next few months.

ENTERPRISE.—The local electric light plant, owned by Mr. J. F. Johnson, has been completely destroyed by fire. The loss is estimated at $5000.

WESTON.—The City Council has granted a franchise for the establishment of an electric light and power system to the Preston-Par Milling Company.

SALEM.—The Citizens' Electric Light & Traction Company, of Portland, has purchased the local electric plant and expects soon to make extensions to its railway system.

MEDFORD.—The Medford Electric Light Plant, formerly owned by Mr. R. A. Proudfoot, is now operated by the town as a municipal plant, and Mr. F. F. Loder is superintendent.

PORTLAND.—The directors of the Lewis and Clark Fair have awarded the contract for light

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

and power during the Exposition period to the Portland General Electric Company for $82,000.

NEWBERG.—Mr. C. J. Edwards, proprietor of the local electric lighting plant, is preparing to increase the capacity of his lines and will install transformers to reduce the current to the proper voltage for use.

ASHLAND.—The Ashland Electric Power & Light Company expects to install soon a 200-kw. generator and a 300-h.p. water wheel. The company is controlled by the Siskiyou Electric Power Company, of Yreka, Cal., the plant here being in charge of Mr. J. W. Potter, superintendent.

MARSHFIELD.—Messrs E. C. Drews and E. Riggs are reported to be contemplating the establishment of an electric light and telephone system. Mr. Drews was formerly manager of the Sunset Telephone Company for Whitman County, which position he recently resigned to engage in the present enterprise.

PORTLAND.—Messrs. G. W. Waterbury, C. W. Miller and E. D. Whitney have incorporated a power, light and heat company here. They represent Chicago capital and propose to erect a large power plant about 25 miles from Portland near Mount Hood on the Sandy River. The company is capitalized at $100,000.

PENNSYLVANIA.

BOLIVAR.—The Electric Light, Heat & Power Company is building a new plant.

ALLEGHENY.—The council of this city has authorized the issuance of $40,000 electric light bonds.

OAKDALE.—The plant of the Oakdale Electric Light Company has been sold to Mr. W. J. Brown, of this city.

HYNDMAN.—The Hyndman Electric Light, Heat & Power Company is considering the installation of a new engine.

STRASBURG.—Mr. L. J. Blair, proprietor of the electric lighting plant here, is installing a small steam engine and boiler.

HONESDALE.—A new 300-h.p. water heater is being installed in the plant of the Honesdale Consolidated Light, Heat & Power Company.

BELLEVUE.—The Ohio Valley Electric Company, of this place, is now owned by the Allegheny County Light Company, of Pittsburg.

SOMERSET—The Town Council is stated to have granted James M. Coyer, James McKelvey and Fred Biesecker a franchise for an electric light plant.

AVOCA.—The Standard Electric Light, Heat & Power Company is enlarging its electrical and steam equipment and making extensions to its service lines.

SEWARD.—The Seward Heat, Light & Power Company has been incorporated with a capital of $5000. Messrs. D. B. Anderson, Alex. Kerr and Bert Wagner are the directors.

COATESVILLE.—The Consumers' Electric Light, Heat & Power Company has nearly completed the erection of its new plant and it is expected to be in operation very shortly.

McKEESPORT.—The ordinance recommended by the Finance Committee of the Council providing for an issue of $125,000 bonds to be used for the construction of a municipal electric light plant, has been passed.

NICHOLSON.—The following are the officers of the Nicholson Light, Heat & Power Company: President, F. E. Platt; secretary, James G. Sanderson; treasurer, manager and superintendent, Moses Shields, Jr.

SHICKSHINNY.—Mr. Briggs has resigned his position as superintendent of the electric light plant here to accept a similar position with the Irondale Electric Light, Heat & Power Company, of Bloomsburg, succeeding Mr. W. O. De Witt.

VANDERGRIFT.—The following officers have been elected by the Vandergrift Electric Light & Power Company: President, E. W. Pargey; vice-president, S. A. Davis; secretary, Joseph Murphy; treasurer, H. W. Pratt; purchasing agent, J. F. Horn; consulting engineer, A. Pinkerton.

WILLIAMSPORT.—The contract for lighting streets and engine houses for ten years has been awarded to the Lycoming Electric Company for 221 arc lights at $60 per light per year, $18 per light per year for incandescent lights, and for light in engine houses and city hall 10 cents per kilowatt-hour.

BLOOMSBURG.—Mr. W. O. De Witt, formerly superintendent of the Irondale Electric Light, Heat & Power Company, has accepted the superintendency of the new plant being erected for Mahanoy City and Shenandoah by the People's Electric Light, Heat & Power Company. He is succeeded at Bloomsburg by Mr. Briggs.

HATBORO.—The Hatboro Electric Light Company, formerly owned by Smith & Davis, has been incorporated with a capital stock of $25,000. The following are its officers. President, A. J. Smith; vice-president, H. L. Chandler; secretary and manager, W. W. Wilgus; treasurer, C. L. Leland; chief engineer and electrician, William Evans.

LORETTO.—The City Council has under consideration an offer of $1,000,000 from Mr. Charles M. Schwab, the amount to be expended in improvements in the town, where Mr. Schwab spent his boyhood. The improvements will include the paving the streets and the erection of an electric light plant and water works; a complete system of sewer and water pipes will also be laid.

HALLSTEAD.—The Union' Electric Company has been consolidated with the Susquehanna Electric Light & Power Company under the style of the Susquehanna County Electric Company. The latter company is capitalized at $100,000 and is officered as follows: O. S. Johnson, president; F. J. Platt, secretary, treasurer and manager; John K. Harris, superintendent and chief engineer and electrician. Besides lighting Hallstead, the company's generating plant furnishes lighting current to Great Bend, where it is distributed through a sub-station equipped with two 50-kw. 6000/1000-volt transformer and one constant-current transformer.

CHARLEROI.—The People's Electric & Manufacturing Company has been absorbed by the Monongahela Valley Electric Company, which has a capital stock of $100,000 and the following officers: President, Robert J. Linton; secretary, treasurer and manager, John L. Redinger; superintendent, G. P. Lysinger. Lighting current is furnished to California, Allenport, Fayette City, Bellvernon, North Bellvernon, Monasson and Speers. The company is considering increasing and improving its equipment; the new machinery will include 300-h.p. boilers, one arc machine, a direct-current power generator, 600-h.p. engines, and the necessary accompanying apparatus.

PITTSBURG.—Mr. Charles E. Warner, formerly general superintendent of the Allegheny County Light Company, of this city, has been appointed general manager of the San Juan Light & Transit Company, which operates an extensive electric lighting and traction system in the capital of Porto Rico. Mr. Warner is a western man, having been engaged at one time in practical work in railway and lighting construction in New Westminster, Vancouver, Nanaimo and Portland. He was also manager of the Northwestern agency of the Westinghouse Electric & Manufacturing Company in Tacoma, Wash., for five years from 1893 to 1898. During this time he also had charge of the surveys and development work on the White River power project, one of the largest hydraulic-electric power enterprises in the Northwest.

RHODE ISLAND.

BRISTOL.—The Bristol County Gas & Electric Company is now controlled by the Narragansett Electric Lighting Company, of Providence. Mr. Marsden J.' Perry, of Providence, is manager of the plant and Mr. W. I. Barnes is superintendent.

WESTERLY.—The arrangements of the Westerly Gas & Electric Light Company for putting in a power circuit to supply day power for motors, fan motors and day electric lights, have been completed and the circuit is now in operation. The company has also completed its work of stringing new wires for more electric lights at Watch Hill.

WESTERLY.—The People's Light, Heat & Power Company, of Westerly, which recently took over the Mystic Electric Light & Power Company, has completed arrangements for the absorption of other corporations. It has acquired the Pawcatuck Valley Street Railway Company, the South Shore Gas & Electric Company, and the Westerly & Hopkinton Railway Company. The Railway & Lighting Company now has a monopoly of the electric lighting business in the Rhode Island village of Westerly and the Connecticut villages of Pawtucket, Stonington, Mystic and Noank. The corporation already has 6 miles of street railway in operation and 7½ miles in the course of construction.

SOUTH CAROLINA.

FORT MILL.—The directors of the Catawba Power Company at a recent meeting decided to increase the capital stock of the company from $750,000 to $850,000.

GEORGETOWN.—The Georgetown Electric Company is installing an additional 60-kw. alternator, making in all three units of this kind now in operation in the plant.

ABBEVILLE.—The Abbeville Water, Light & Power Company has under consideration extensive improvements at its plant, which include a new power house and the installation of a storage battery, insulator, engine, boiler, etc.

NEWBERRY.—The commissioners of public works of Newberry have purchased the new electric lighting plant for the city. The purchase was made from the General Electric Company, Schenectady, N. Y. The new plant will be installed within the next few months. The purchase price of the new system was $5905.

BELTON.—The previously mentioned Belton Power Company has been granted a charter by the Secretary of State. The company's capital is $100,000, and arrangements have been completed for the establishment of a large electric power plant in this city. About 5000 horse-power will be developed from the flow of Saluda River and transmitted to Williamston for the operation of cotton mills. Electric lights and water will also be furnished to Belton.

SOUTH DAKOTA.

STURGIS.—The plant of the S. A. Oliver Electric Light Company, which furnishes light for this city and Fort Meade, has been enlarged by the addition of two 200-h.p. boilers.

TENNESSEE.

SPRINGFIELD.—Bids for the construction of a water works system and an electric light plant have been advertised for.

JEFFERSON CITY.—The Jefferson City Electric Company is considering changing over from water-power to steam as a means of operating its plant.

DYERSBURG.—Mr. H. F. Goostreet is superintendent of the city electric lighting plant. All current is sold by meter at 10 and 15 cents per kilowatt-hour.

MURFREESBORO.—Mr. J. H. Nelson, who owns the electric light plant of this place, expects to substitute next year arc lamps for the present street incandescent lights.

MORRISTOWN.—Mr. J. F. Mathes has been appointed superintendent of the city electric light plant, with Mr. John Stephens as chief engineer and Mr. W. H. Akers, assistant engineer.

SARDIS.—A charter has been issued to the Sardis Electric Company, recently organized, with a capital stock of $25,000. The incorporators are D. L. Rush, W. R. Roberts, W. H. Harvey, L. L. Pearson and Rhea P. Carey.

NASHVILLE.—The proposed water-power electric plant for this city is assured by the statement that Meikelham & Dunsmore, of New York City and C. H. Ackerman, of Binghamton, N. Y., have arranged for the placing of $100,000 of stock and the disposal of $4,000,000 of bonds of the Great Falls Power Company. This company is promoted by C. H. Fisk, of Detroit, Mich.

TEXAS.

DUBLIN.—The Dublin Light & Power Company announces that it is in the market for a new 100-h.p. boiler.

SULPHUR SPRINGS.—A new 120-kw. generator, direct-connected to a 150-h.p. engine, will be

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

installed in the electric light plant owned by B. T. Ashcroft & Sons.

LUFKIN.—The Lufkin Light & Power Company is composed of Hackney & Henderson. Mr. J. S. Henderson is manager of the plant, and Mr. F. M. Stephens is chief electrician.

GROESBECK.—J. C. Anglin & Company own and operate the electric light plant here. J. C. Anglin is manager and purchasing agent; John Berkeleyl, superintendent, and J. F. Brown, chief engineer and electrician.

BLOSSOM.—Blossom is to be lighted by electricity supplied by an electric light plant which is to be installed in the mill of the Blossom Oil & Cotton Company. The necessary machinery has been purchased and it is expected to have the plant in operation some time this month.

AUSTIN.—Mr. F. H. Brun has been appointed superintendent of the city water works and electric light and power plant; Mr. Walter F. Johnson is chief engineer, and Mr. George Fegel, Jr., chief electrician. The city also controls the Austin Water, Light & Power Company.

ARLINGTON.—The Arlington Light & Power Company has been organized and incorporated with a capital stock of $10,000, for the purpose of installing and operating an electric light and power plant. Messrs. A. W. Collins, William Dugan, W. L. Sweet, E. A. Hood and W. Weeks are named as the incorporators.

BAY CITY.—The Bay City Ice, Light & Power Company, which was organized not long ago with a capital stock of $50,000, now has its plant in operation. The following are the officers: President, I. Marks; vice-president, Henry Blethen; secretary, general manager and purchasing agent, J. H. Craig; treasurer, Henry Rugeley; chief engineer and electrician, William Fries.

SAN ANGELO.—The Concho Water Power Company has just completed a large wing dam on the South Concho River. The dam, which is built of stone and concrete, has cost in the vicinity of $2500. The total length of both wings is 500 feet. This gives a spillway of twice the width of the river. A mill race 700 feet long leads to three turbine wheels. These will supply power for lighting the city and for pumping the city's water supply.

UTAH.

RICHFIELD.—Several local capitalists propose building an electric light and power plant here in the near future.

SALT LAKE CITY.—The Utah Light & Railway Company has let the contract for building a transformer station near its plant on the Jordan River at a cost of $15,000.

SALT LAKE CITY.—Mr. W. S. McCornick, a wealthy banker of this city, is said to have purchased the plant and property of the Salt Lake City Water & Electrical Power Company located at the Jordan Narrows.

AMERICAN FORK.—The Utah County Light & Power Company, of this city, is considering a proposition to light Salt Lake City with power from American Fork Canyon. For this purpose it is intended to erect a plant of about 1000 horse-power capacity 1½ miles above the present plant.

VERMONT.

MONTPELIER.—A new 200-h.p. generator is being put in at the Pioneer steam plant of the Consolidated Lighting Company to run the Barre & Monteplier Street Railway direct from the power station.

BENNINGTON.—The Bennington Water Power & Light Company may change its street lighting system from direct-current series arc to alternating-current constant-potential. Tub transformers will be used.

BURLINGTON.—The council has advertised for bids for furnshing labor, material and the necessary equipment for installing a complete electric plant in this city, the plant to have a capacity of 250 kilowatts.

VIRGINIA.

HOLLAND.—A franchise has been granted to local parties for the construction and operation of an electric light plant.

MARION.—The Marion Light & Power Company is building a new dam in order to increase the capacity of its plant, and will soon place an order for a new three-phase 60-cycle dynamo.

NORFOLK.—The People's Light, Heat & Power Company is being organized here and will apply for a franchise to operate an electric light and power plant. The company will have a capital of $100,000.

RICHMOND.—An ordinance has been introduced in the council providing for a bond issue of $300,000, the money to be used in the construction of an electric light and power plant on the site of the old pump house.

LYNCHBURG.—The Lynchburg Traction & Light Company is building a new 4000-h.p. water power station for the transmission of electric power. It is expected to have the new line in operation by December 1, this year.

SUFFOLK.—The Suffolk Light & Ice Company has elected the following officers: President and manager, G. W. Fruitt; vice-president, G. C. Guvernator; secretary and treasurer, R. J. Brinkley; chief engineer and electrician, A. E. Harvell.

FRONT ROYAL.—Recorder W. J. Kendrick writes that the contract for the electric light machinery to be installed in the new municipal plant now in course of construction has been awarded to the Rumsey Electric Manufacturing Company for $5000.

NORFOLK.—The Williams interests, controlling the Norfolk Railway & Light Company, will, it is said, expend $500,000 in new heating and ice plants. The company has met with great success in disposing of electric power and is now working out plans for greatly extending its interests.

ALEXANDRIA.—The council has granted to Charles F. Thompson a franchise for an electric light and power plant, in consideration for which he proposes to pay the city a bonus of $10,000, to take over the present light plant at $3500, to furnish the city with 39 or more arc lights for the streets, etc., at $76 per annum each, and to give bond that the work shall be begun in six months and completed within a year.

WASHINGTON.

CASTLE ROCK.—Mr. John Leffler has been appointed manager and superintendent of the plant of the Castle Rock Electric Company.

CHEWELAH.—D. Van Slyke and D. F. Strobeck are reported to have secured a franchise for an electric light plant and water works.

HARRINGTON.—Mr. H. W. Fellows, an electrical engineer of Spokane, contemplates establishing an electric lighting plant in this city.

GREENWOOD.—The owners of the Providence Mine here are planning to install a complete electrical system at the mine, power for which will be furnished by the Cascade Power Company.

PROSSER FALLS.—The Prosser Falls Electric Company is contemplating installing electric light and power plants in Mabton and Sunnyside.

ELMA.—George A. Avery and Charles Anderson, of Olympia, have secured a 25-year franchise for the operation of an electric light plant.

SEATTLE.—The Moseley-Yates Lighting Company has been incorporated with a capital of $100,000 by Messrs. J. H. Yates, of Spokane; Hiram W. Moseley, Edward M. Cox, John H. Corcoran and H. M. Herrin.

SPOKANE.—The Spokane Water Power Company is developing 14,000 horse-power at the lower falls. With this it will light the city, run the street car system and transmit 1800 horse-power to the mines in the Couer d'Alenes district. The company is also preparing to build an electric line to Medical Lake over the old right of way of the Seattle, Lake Shore & Eastern Railroad which was recently acquired.

SEATTLE.—The great steel receiving tank, made in Pennsylvania for the Cedar River municipal light and power plant, is now at hand. This is the last piece of apparatus to be installed, and with this in place, all that remains to be done to complete the system is the completion of the pole line. The tank will receive the water from the dam 604 feet above, whence it will be sent to the water wheels. The engineer in charge of the work states that it is expected to have the plant in operation some time in October.

WEST VIRGINIA.

NEW CUMBERLAND.—Press reports state that the City Council has considered favorably the plans of Engineer W. J. Miller, of Wheeling, for water works and an electric light plant.

WISCONSIN.

SHEBOYGAN.—The Sheboygan Light, Power & Railway Company is preparing to spend about $37,000 in rewiring its system.

LADYSMITH.—The Ladysmith Light & Power Company is now engaged in the development of water power 4½ miles south of here on the Flambeau River.

SPRING VALLEY.—The Village Board has adopted plans and specifications for a municipal electric lighting plant to cost about $10,000 and to be completed this fall.

VIROQUA.—The Viroqua Electric Light Company expects to add a 75-h.p. Corliss engine and a 50-kw. alternating-current generator to its plant equipment before the year is out.

MILWAUKEE.—Local press reports are to the effect that the Finance Committee has formally approved the issue of $150,000 bonds with which to construct an electric light plant.

RICHLAND CENTER.—The plant of the Richland Center Light Company, which was owned by G. H. Strang, has been turned over to the city and will be operated in the future as a municipal plant.

MILWAUKEE.—The Milwaukee Electric Railway & Light Company has been granted a permit to erect a $100,000 addition to its Commerce Street plant. The addition will be four stories high and 83 x 144 feet.

CLINTONVILLE.—The Clintonville Electric Light Company is about to enlarge its power house and will install a duplicate set of equipment as soon as the extension is completed. Mr. H. H. Cole is superintendent.

RHINELANDER.—The Rhinelander Power Company has about ready its plans for the dam and power house to be constructed at Hat Rapids. The structure will probably be of concrete with steel bulkheads and steel beams.

NEW RICHMOND.—By the breaking of a piece of machinery recently in the municipal electric light plant in this city the plant was badly wrecked. One of the dynamos was completely destroyed and other machinery and apparatus about the plant was broken.

SPRING GREEN.—The electric light plant of this place, formerly owned by G. F. Post, has been operated as a municipal plant since June of this year. It is stated that meters, new transformers and No. 0000 wire, to the amount of $1200, will be installed shortly.

APPLETON.—The plants of the Fox River Valley Gas & Electric Company at Appleton, Neenah and Menasha are said to have been sold to the Wisconsin Traction, Heat, Light & Power Company for $600,000. The deal gives the Wisconsin company complete control of the lighting facilities of Appleton and the twin cities.

WAUSAU.—The city has recently accepted a proposition from the Wausau Electric Company to furnish the city with current for street lighting purposes at the rate of 2.3 cents a kilowatt-hour, or approximately $29.75 per lamp per annum on the basis of an all-night schedule. The city is to own and operate all pole lines and lamps, which, it is said, will bring the cost up to $45 per lamp per annum. This is probably about as good a figure as any municipality can boast of for its lighting service. The series-enclosed alternating system is to be used, a constant-current lamp operating an 6.6 amperes being chosen. The buying of current by the city by the watt-hour but still operating its own system of lamps is somewhat unusual, it being the general practice to either build a municipal plant or else pay a stated amount to an operating company, the latter owning the complete system.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

American Electrician.

Vol. XVI. New York, October, 1904. No. 10.

AN INTERESTING FRENCH STEAM-DRIVEN TURBINE PLANT.

THE POWER STATION AT NEUCHATEL.

Power plants which are designed for the supply of electric energy from turbo-generators (hydraulic) are often forced to add a reserve equipment in the shape of steam engines. For example, in the plant at Zurich with 600 hydraulic horse-power there is, in addition, a steam plant of 2800 horse-power. At Chaux-de-Fonde, with 1000 hydraulic horse-power there is 600 horse-power in gas engines, and at Lausanne, with about 1000 hydraulic horse-power there is 1200 horse-power in the steam plant. For several years it has been apparent at Neuchatel that the power furnished by the Areuse was not sufficient for the development and growth of the distribution system established by the town in 1895 and 1896. The power house near Boudry utilizes a fall of 56 meters (183.7 feet) and is equipped with six turbines of 300 horse-power each, requiring for the production of 1500 horse-power 2700 liters (95.3 cubic feet) of water per second, and the demand from the station constantly approaches this figure.

The Areuse furnishes at low water in the neighborhood of 1600 liters (56½ cubic feet) per second, and this is further reduced by the demands of successive power stations along its course, so that the actual flow may vary between 1000 and 2000 liters (35 and 70 cubic feet) per second in a very irregular manner in the course of a single day. The design of the new power house required considerable time on account of the difficulty in choosing a site. After much discussion, a strip of ground owned by the town upon the Quay de Champ Bougin was decided upon. The location is most excellent, easy of access, and the lake furnishes the necessary water; the value of the site being the cause of hesitation.

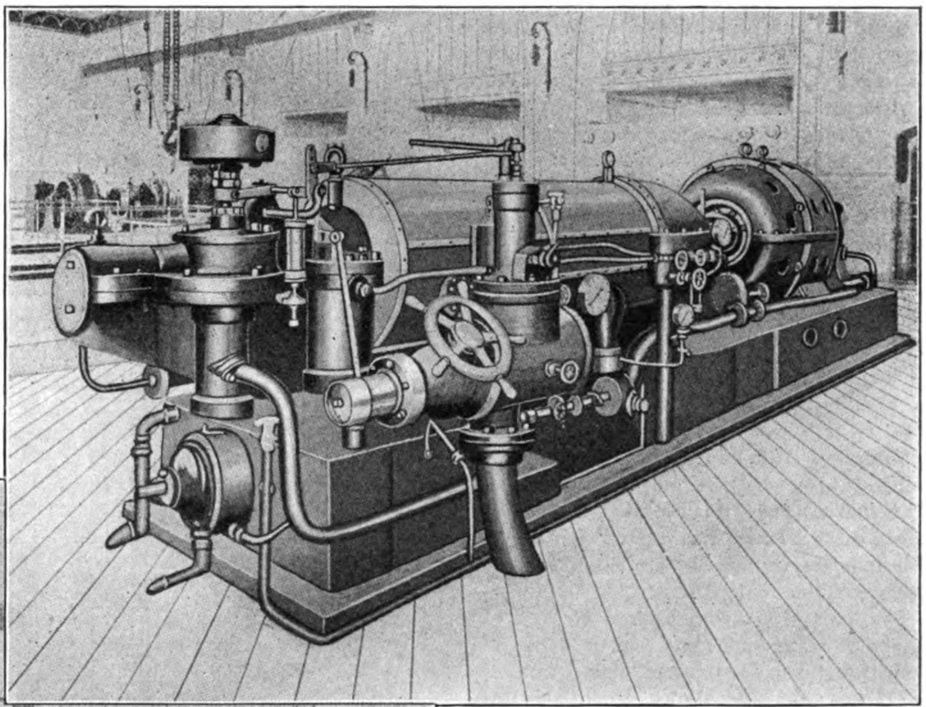


FIG. 2.—TURBO-GENERATOR AT NEUCHATEL.

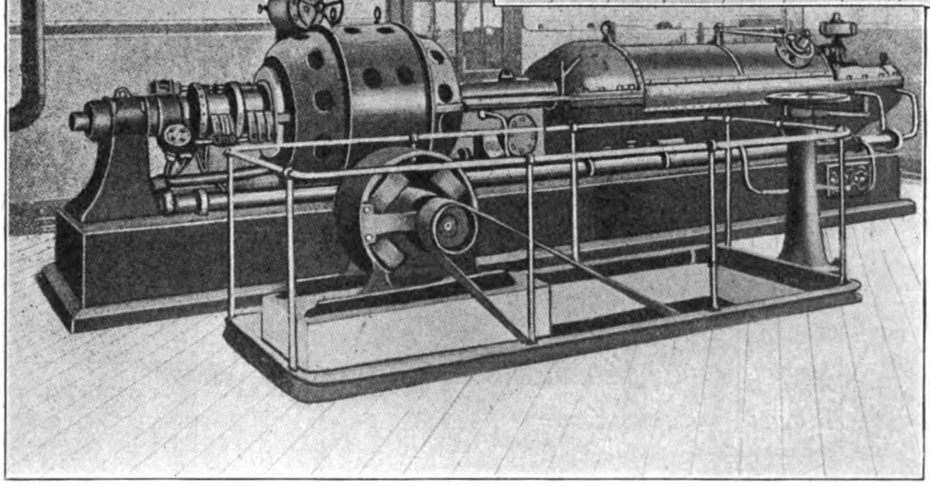

FIG. I.—TURBO-GENERATOR SHOWING MOTOR FOR OPERATING CONDENSER.

The two electric railways of the town were receiving their current from two transformer stations belonging to two companies. The fusion of these companies and the development of their system rendered an increase in the capacity of these stations necessary. The town has acquired one of these installations and has made arrangements with the company to deliver direct current, including in its charge the cost of transformation and generation. The choice of steam as the source of thermal energy has been dictated by the first cost and the facility with which it may be used. A short study was made of gas engines, which are in vogue at the present time on account of their economy in the use of combustible, and the results of this study differ in no way from those obtained in similar cases. The towns of Chaux-de-Fonde and Bale, which have installed gas engine plants, seem almost ready to abandon their use.

thus justifying the decision in the present case. The choice of steam turbines was, moreover, imposed by the first site decided upon, and this choice has since been confirmed by a careful comparison with reciprocating engines.

The building is designed for six boilers, each with 2475 square feet of heating surface; four steam turbines of 300 kilowatts each; three rotary converters of 300 kilowatts each, and three converters of 65 kilowatts each. The power house was built with great rapidity. The excavation for the foundation consisted of 3000 cubic yards, of which 2220 cubic yards were in rock. In spite of autumn rains, the building was covered three months after work was begun. The foundations rest entirely upon rock. The excavation was rendered difficult by the presence of a constant sheet of water, and owing to the slight difference in level between the foundations and the lake drainage was rendered troublesome.

Two plans of roof construction were considered, one of steel and brick costing $3700 and the other of armored concrete costing $3500, the latter being used. The preference was given to this latter construction principally on account of the fact that it allowed the greater part of the cost to be expended in the surrounding country, instead of giving out the work to contractors at a distance. The calculation and the working plans for the concrete work were made at Lausanne, according to the patents of Hennebique, and some serious mistakes were made. Portions of the ceiling had to be torn down and reconstructed and other portions reinforced by means of iron plates. The ceilings are covered with asphalt 2 centimeters (0.7874 inch) thick, upon which is placed a covering of slag 20 centimeters (7.8 inches) deep, this covering having the effect of protecting the interior from outside temperature and the asphalt from sudden variations of heat and cold.

The floor of the engine room consists of blocks of white sandstone laid on a bed of asphalt. It has been tested with a tension of 35,000 volts and shows remarkable insulating qualities. The cable ducts are covered with white marble. The lighting of the interior is perfectly assured by the lateral windows. The cost of the building was $24,600, to which must be added: Foundations and masonry for boilers, $2760; chimney, foundation and accessories, $4740; flue, $1035; foundations for machines, foundations in the basement, ducts, masonry and auxiliaries for carrying the cables, $1825; furniture, $80; shed, $315; making a total of $35,355.

The chimney is 55.4 meters (181 ft. 9 ins.) high, with an internal diameter of 3 meters (9 ft. 10 ins.) at the base and 2 meters (6 ft. 6¾ ins.) at the top. It has an ornamental brick top, which relieves the monotony of the structure and was built by the firm of Walzer, of Winterthur. The two boilers are of the water tube type, and have 2180 square feet of heating surface each and furnish steam at a pressure of 12 atmospheres (176 pounds). A superheater with 688 square feet of heating surface is placed under the steam drum in the path of the gases. The water tubes are 140 in number, 3¾ inches in diameter, and are fixed between two rectangular water chambers, one of which is connected with a drum 59 inches in diameter and 22 feet 9 inches long; the drum is normally half filled with water. Sheet iron divisions direct the circulation of the water, so that the two

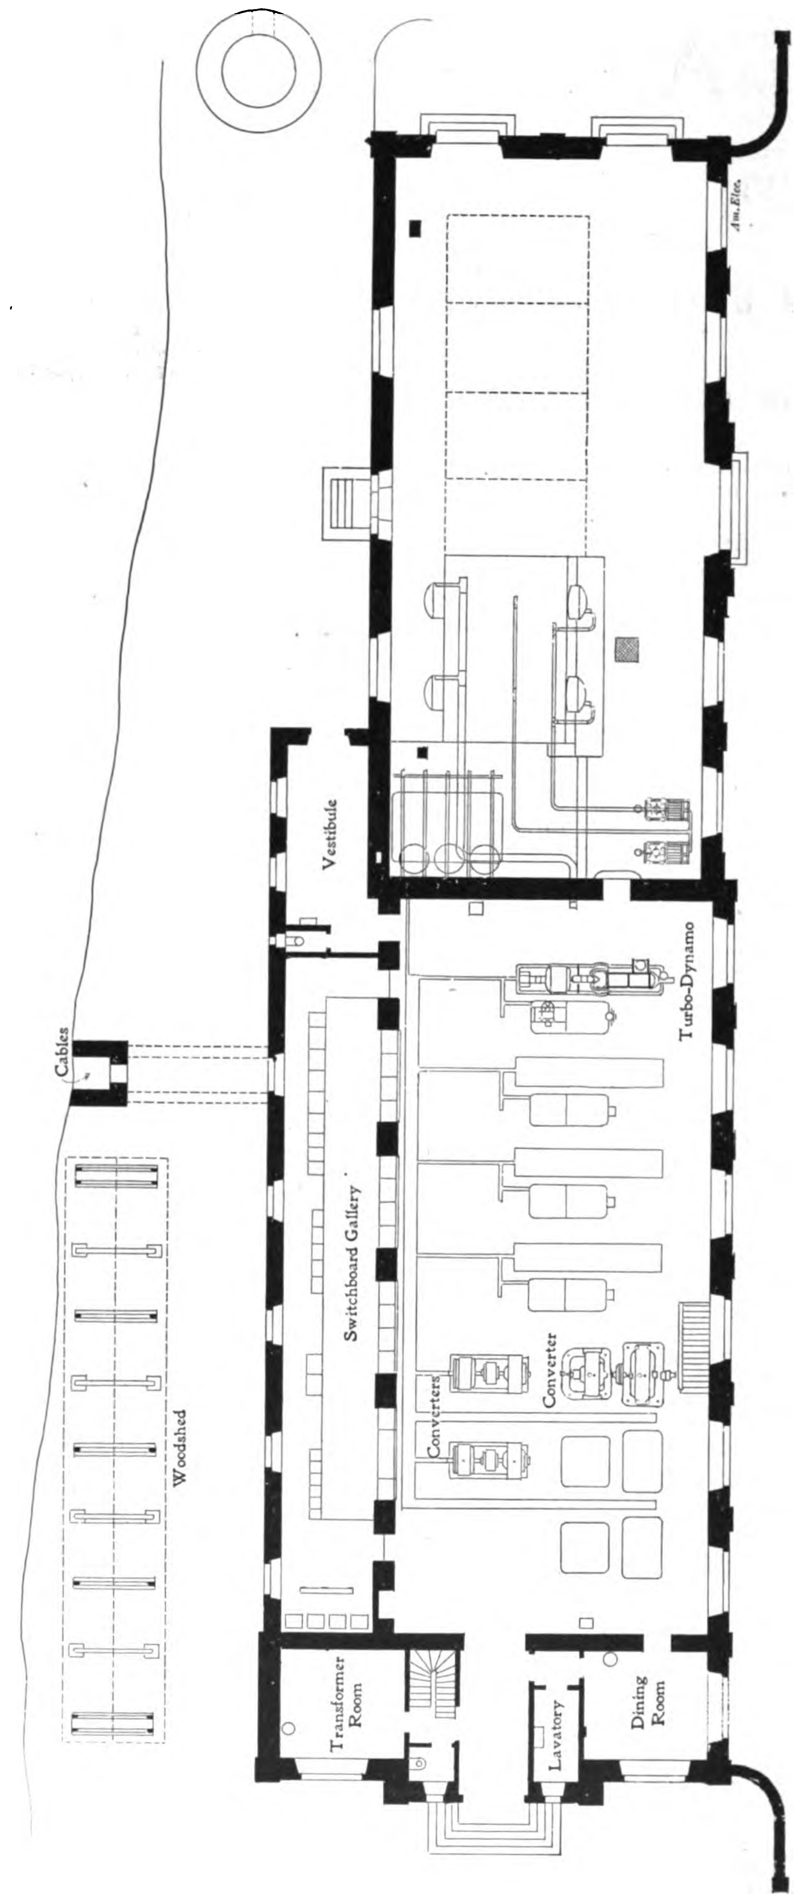

FIG. 3.—PLAN VIEW OF THE GROUND FLOOR.

upper rows of tubes have a descending current and the others an ascending current. The tubes are expanded into the headers, as is customary in this type of boiler, and the joints are removed from the direct path of the gases. The grates have a surface of 48.2 square feet and the normal steam production is 2.46 pounds per square foot of heating surface, with an evaporation of 8.1 pounds of water per pound of coal of 13,400 B.T.U. calorific value. The effect of the superheater is very pronounced at forced loads, 50° Centigrade of superheat being easily obtained; under light loads the superheater hardly does more than dry the steam.

The steam drum contains about 6 cubic meters of water, the total capacity of the boiler being 12½ cubic meters when the water level is up to the middle of the drum. This relatively large volume for a water-tube boiler renders its operation particularly simple. A longitudinal section of this boiler, showing the arrangement of the interior, the location and arrangement of the superheater and the flue, is shown in Fig. 4. The illustration also shows the arrangement for a steam jet which may be added at some future time. As the chimney is designed for six boilers, the draft is very intense for two, and, therefore, the construction of the masonry work necessary for artificial draft is a provision for future growth. Owing to the length of the grates (2 meters) it is very easy to render the fires smokeless if properly handled, but unfortunately there are few firemen who are familiar with the proper method of firing to produce this result.

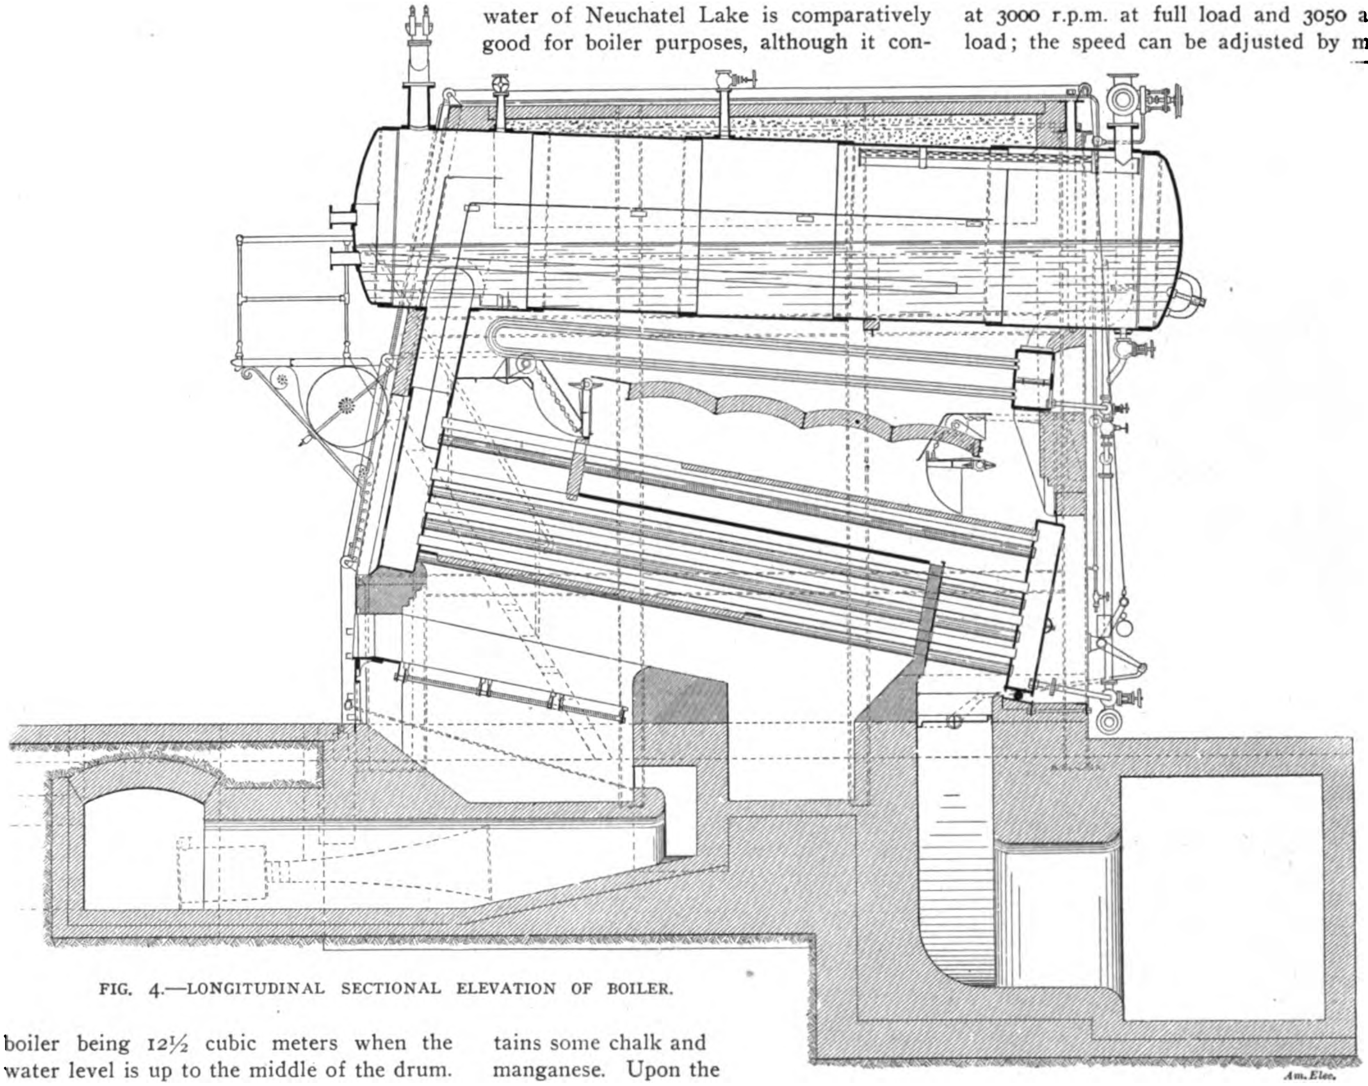

FIG. 4.—LONGITUDINAL SECTIONAL ELEVATION OF BOILER.

Am. Elec.

The boiler is provided with a damper by means of which the gases passing in contact with the superheater may be regulated or shut off entirely. With practice in preparing the fire and with the superheater shut off, the boiler may be brought up to pressure from a cold condition in twenty-five minutes without producing any bad effects, and in practice with an ordinary fire of wood or oil this can be accomplished in little more than an hour. The headers in which are terminated the 140 boiler tubes are made of cast steel without any rivets, and the interior of the tubes is accessible for cleaning purposes by the removal of the usual type of cover. The water of Neuchatel Lake is comparatively good for boiler purposes, although it contains some chalk and manganese. Upon the advice of experts who have examined the conditions, Rossel purifiers, furnished by the Mechanical Construction Society, of Bale, have been installed. These consist of a raised reservoir, with a capacity of 706 cubic feet, into which the water from the lake is pumped by means of a rotary pump operated by an electric motor. Below the reservoirs are the purifiers, consisting of three chambers of 88¼ cubic feet each, in which the water is allowed to stand from one-half to two hours and in which is placed 10.6 ounces of carbonate of soda. By a special pipe, water from the bottom of the boiler may be added in order that the small quantity of precipitated carbonate may be utilized. The purified water is then led into a small reservoir, divided into two parts separated by a filter. The feed pumps take the water from this after it has passed through the filter. Up to the present time no deposit has been found in the boiler tubes. The feed water enters the boiler at the bottom of the drum, as shown in the illustration. The mixture of water and steam which comes from the boiler tubes is projected horizontally upon a casting pierced with openings by which the water is separated. Steam leaves the drum at the top through a perforated longitudinal pipe, and thence enters the superheater.

The turbo-generator was built by Brown, Boveri & Cie., and has a capacity of 300 effective kilowatts with steam at 162 pounds pressure at the throttle. The turbine runs at 3000 r.p.m. at full load and 3050 at no load; the speed can be adjusted by means of the regulator through a range of 10 per cent. The steam turbine is of the Parsons type, as shown in Fig. 2. The lubrication is practically the same as that of English turbines. The oil is delivered under moderate pressure into a circular canal between the interior bearing and the axle. The oil pump is operated by a countershaft geared to the axle of the regulator, and draws its oil from a reservoir placed in the basement, through which a circulation of cold water is kept up. The temperature of the oil does not exceed 40° Centigrade.

The regulation of the amount of steam cannot be effected by reducing the section of the first chamber, so that it is necessary to arrange for throttling the entrance.

The difficulties of regulating under these conditions and the ingenious solutions proposed to accomplish the result are well known. Mr. Parsons has adopted an oscillating valve, the center of oscillation varying according to the position of the governor. The valve is oscillated by an eccentric mounted upon the shaft of the governor or upon the shaft of the oil pump. The number of oscillations varies with different types, it being 120 per minute at Neuchatel. At each oscillation, due to the play of the valve, the piston attached to the admission valve is raised a certain distance, the turbine thus receiving puffs of steam at the rate of 120 per minute, the volume being controlled by the governor. An additional regulator, operated by hand, is provided in case of failure of the automatic governor. Attempts have been made to control the speed by means of a solenoid in order to obtain a constant electric pressure with a variable speed. Up to the present time, however, this method has not been adopted by Brown, Boveri & Cie.

The dynamo is mounted on the turbine shaft, of course, and is compound wound, but the shunt and series fields are not superposed, but placed at right angles. The object of this is to avoid displacement of the axle of commutation and sparking at the brushes. The commutator is very long and is provided at the center and either end with a steel loop to resist centrifugal force. The brushes are of curved form. The operation is very satisfactory, without heating or sparking, and without rendering it necessary to move the brushes with variations of load. The only inconvenience of this system is that it requires compound or overcompounded dynamos in order that the voltage may vary with the load.

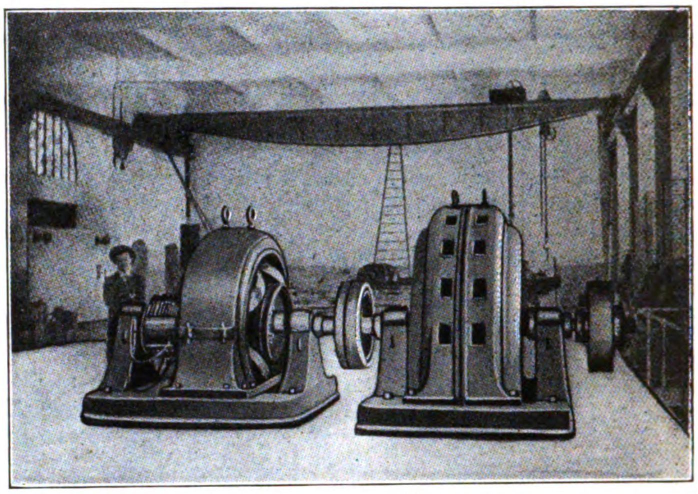

FIG. 5.—250-KW. MOTOR-GENERATOR.

The condenser pump is operated by an independent electric motor located near the turbine and belt-connected to the pump.

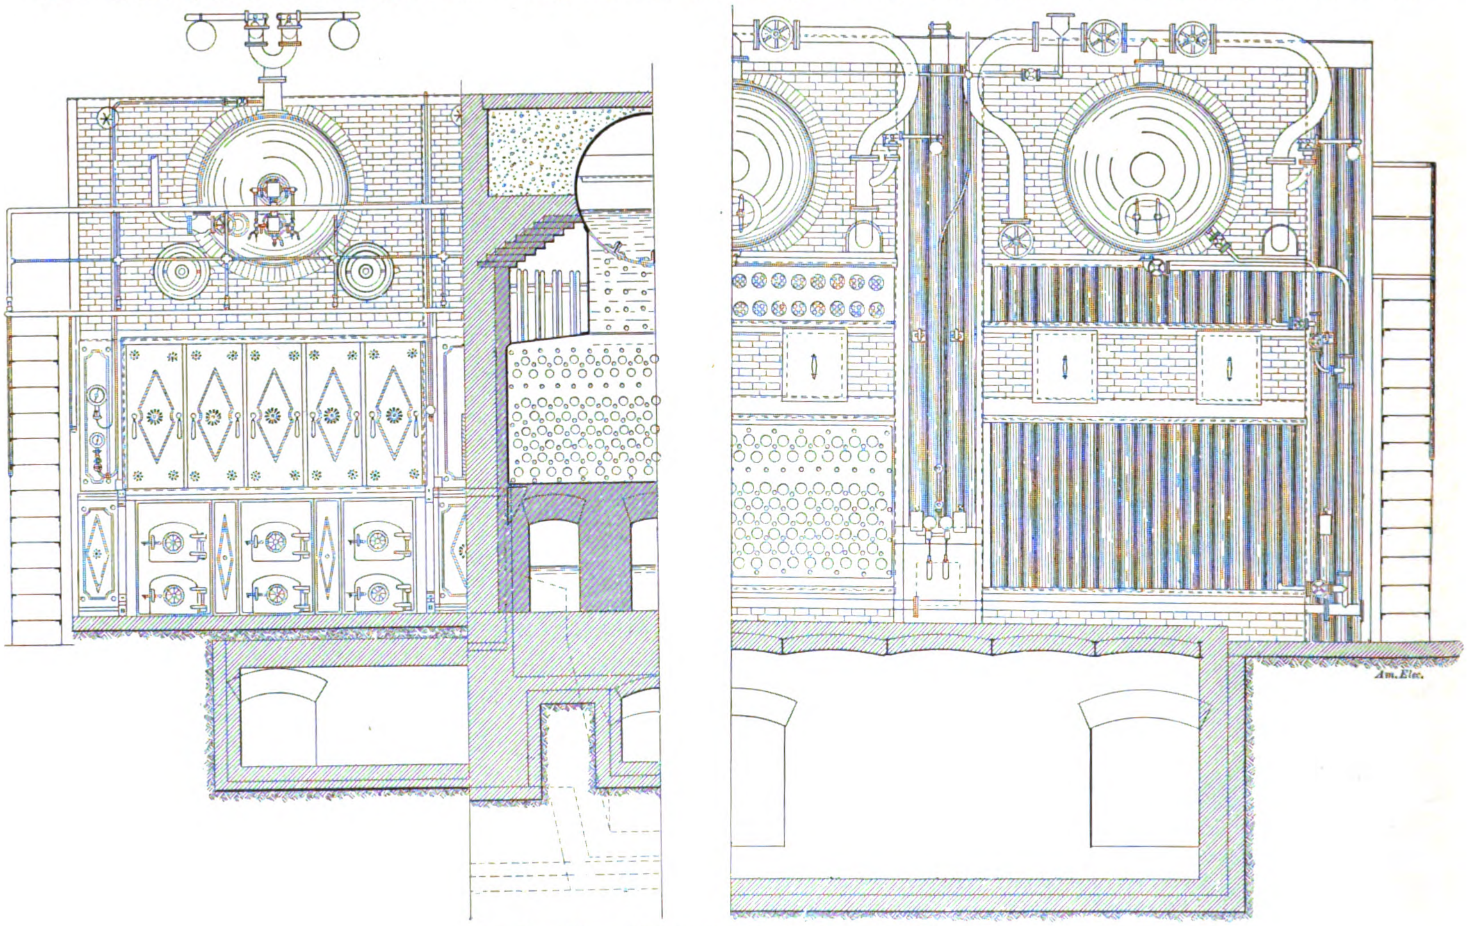

FIG. 6.—FRONT AND REAR ELEVATION OF BOILER.—FIG 7.

The constructors' guarantees are based on the use of dry saturated steam at 162 pounds pressure at the throttle and also on the consumption per effective kilowatt-hour. Under these conditions the guarantees are 24.86 of steam per kilowatt-hour at full load and 27¾ pounds at half load, the temperature of the water of condensation not to exceed 20° Centigrade. Results inferior to these are often found with turbines of the same power. At Coire, with a 200-kw. turbine, using steam at a pressure of 12½ atmospheres and superheated to 250° Centigrade, the tests showed a consumption of 24.14 pounds per effective kilowatt-hour; at Tschopeln a 400-kw. turbine, using saturated steam at 7½ atmospheres, showed a consumption of 23.15 pounds per kilowatt-hour, the guarantee being 26.45 pounds. Two series of tests were made on the machines for Neuchatel, the first at Baden and the second at the power house of Champ Bougin. The figures, reduced to effective kilowatts at full load, are given herein, deducting the energy required for the motor which operates the condenser pump. The test at Baden showed a steam consumption of 23.1 pounds per kw.-hour and at Neuchatel a figure somewhat higher. At Baden, however, more accurate measures were used, the condensed water being measured as it came out of the turbine, all leakage deducted, and a surface condenser used. On the contrary, at Neuchatel, it was necessary to measure the water as it entered the boilers, thus neglecting all the leakage, and the precision of measurement left considerable to be desired. However, this same test having served to verify the guarantees regarding the performance of the boilers, and as these with the employment of a poor quality of fuel have exceeded the guarantees, it is probable that a slight error was made favoring the boilers and to the detriment of the turbines. There was also a second cause for error, due to the fact that the electrical measuring instruments were not absolutely correct. The results of the Baden tests are given below:

290 kilowatts saturated steam, 23.1 pounds per kilowatt-hour.
311 kilowatts superheated steam, 38° C., 21.23 pounds per kilowatt-hour.
140 kilowatts saturated steam, 27.58 pounds per kilowatt-hour.
145 kilowatts superheated steam, 28° C., 25.198 pounds per kilowatt-hour.
No load, dynamo excited, 917.12 pounds per hour.
No load, dynamo not excited, 881.85 pounds per hour.

The last two figures are included in the result to account for the work of condensation, and should add in the neighborhood of 550 pounds per hour, or 10 kilowatts at 55 pounds. To establish these figures the work of condensation, which was not measured, was assumed as 10 kilowatts. At Neuchatel this work was measured and found to be somewhat less than the value assumed, thus serving to make the test at Baden show up even better.

The power furnished by the hydraulic power station at Pre-aux-Clees, near Boudry, is three-phase at 33 cycles per second and 3800 volts. The railroad company had at Neuchatel a small power station which was not used, where it had installed rotary converters. The inconveniences arising from their use, however, were such that in the power house at Champ Bougin motor-generator sets were installed. The power house contains two sets of 100 horse-power each, consisting of a three-phase induction motor operating at 3800 volts and a separately excited dynamo furnishing current at 500 to 720 volts and running at 650 r.p.m. Another set consists of a synchronous motor and generator, the combination having a capacity of 250 kilowatts output. The use of this motor was necessitated by the small size of the feeders entering the power house. All future sets are to be equipped with induction motors.

The plans of the power house show a lateral passage communicating by four large bays with the engine room. In this passage is the switchboard galley, as shown on the plan, containing the distribution switchboard for the three-phase and single-phase, high-tension current and for the direct current at 580 volts. The apparatus which requires manipulation, or the indicating appliances which are continually used, are located in the bays at the side of the room. The conductors which lead from the switchboard and the machines are in lead-covered cables placed in ducts, the floor of the room having been provided with deep trenches covered with white marble slabs. A subcellar is often preferred for the conductors, but the foundation of this power house being of hard rock and difficult to work, and the proximity of the lake rendering it damp, this disposition of the cables has been found more economical. The interior arrangement of the building is clearly shown in the plan.

DECORATIVE LIGHTING AT THE LOUISIANA PURCHASE EXPOSITION.

BY J. R. CRAVATH.

In the creation of a modern exposition two of the most important elements are the work of the architect and the work of the engineer who plans the decorative lighting. The expositions of the past fifteen years have been something more than aggregations of structures housing exhibits. The design and situation of buildings which produced the spectacular effects now so familiar have by public demand become inseparable from great expositions and probably attract as many, if not more, people than the exhibits themselves. After the architect, the sculptor and the landscape gardener have performed their work, a great task still remains for the lighting expert and electrical engineer. The work of the architect and landscape gardener makes the site attractive by day only, but an exposition is demanded that is attractive at night. Great and beautiful though the creations of the architect and sculptor may be, they are as nothing at night until the skill of the illuminating engineer transforms them into palaces of light. Disregarding the architecture which forms the foundation for the decorative lighting, there is no doubt but what the night illumination is directly responsible for more paid admissions to the grounds than any other single feature.

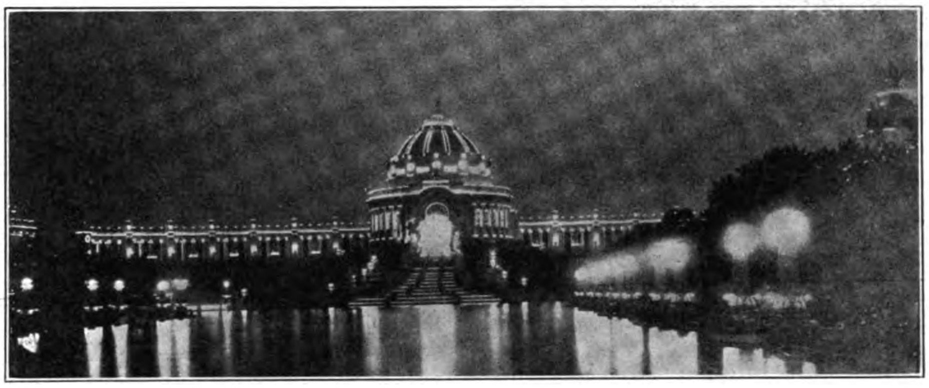

FIG. I.—FESTIVAL HALL AND THE CASCADES.

The decorative lighting of exposition buildings is somewhat of an evolution. Time was when these places were dark and dreary at night, for the reason that there were no means of lighting the building exteriors. Not until the incandescent lamp came into the field has decorative lighting become possible; and not until long after its adoption for commercial use was its value for exposition work sufficiently recognized. The present plan of lighting may be considered as the outcome of the towers of light, etc., seen inside the buildings at earlier expositions.

Although incandescent lamps were used to some extent to outline the buildings at the Columbian Exposition at Chicago in 1893 and at later expositions, it was not until the Trans-Mississippi Exposition at Omaha in 1898 that it was used in the main vistas to the exclusion of all other illuminants. The late Luther Stieringer, whose name was closely associated with the decorative lighting of almost every exposition in this country for twenty years up to and including the Pan-American Exposition at Buffalo in 1901, was for a long time previous to 1898 a firm believer in the exclusive use of the incandescent lamp for purely decorative illumination, but found difficulty in persuading exposition authorities to adopt his views. The incandescent lamp was used at Omaha, however, and ever after. At the Pan-American Exposition a night effect was produced the equal of which had never before been seen.

To Henry Rustin fell the responsibility for planning the decorative lighting at the Louisiana Purchase Exposition at St. Louis. He and his assistant, R. H. Moore, had before them a large undertaking. They had the expositions at Buffalo and at Omaha as guides, but the distances from which the illumination would be viewed were much greater at St. Louis, and the square feet of building surface to be covered much larger. Nevertheless, the results are extremely gratifying, and, notwithstanding the great difficulties, the nightly illumination is as popular and attractive a feature as at other previous expositions. One of these difficulties arises from the fact that the buildings are arranged in such a manner that, contrary to the precedents set by previous expositions, there is no one spot where the observer can get a comprehensive view of the greater part of the decorative lighting. Unlike Chicago, Omaha or Buffalo, the visitor must get impressions of the illumination at St. Louis somewhat "on the installment plan. A "Court of Honor," which will afford one comprehensive view surpassing all others, is not to be had at St. Louis. There are, however, innumerable places where various new and charming vistas will be opened up if one hunts for them.

The nearest approach to the Court of Honor of previous expositions is in the view obtained when approaching the Cascades and Festival Hall from the main entrance, crossing the Plaza of St. Louis; but even there foliage and great distances somewhat dwarf the effect until the grand basin in front of the Cascades and Terrace of States is reached. Here the view is as shown in Fig. 1.

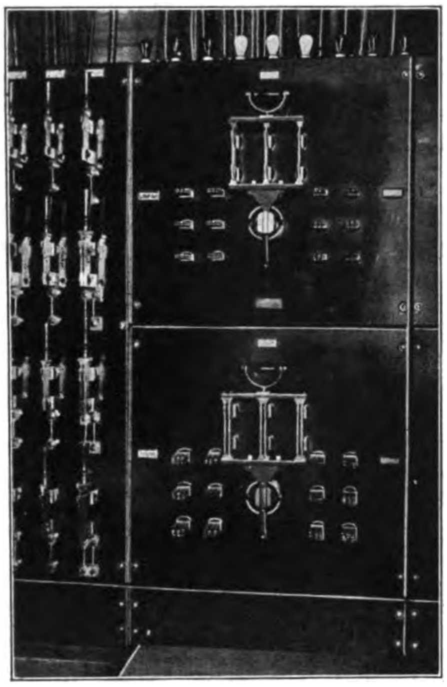

FIG. 2.—TRIPLE-THROW SWITCHES.

Festival Hall, the dome of which forms the central feature of this view, is the most intensely lighted of the exposition buildings, as it is the center and climax of all the lighting. Out of the front of Festival Hall comes the water of the Cascades, which flows in a constantly widening stream from terrace to terrace until the lagoon is reached. Green incandescent lights are placed beneath the water in rows under each terrace. When the exposition opened the lighting of the waterfall was decidedly poor and added little to the general effect. Since the opening, the addition of a searchlight on the Palace of Electricity, with its beams thrown on the water as it emerges at the top of the Cascades, has improved matters somewhat.

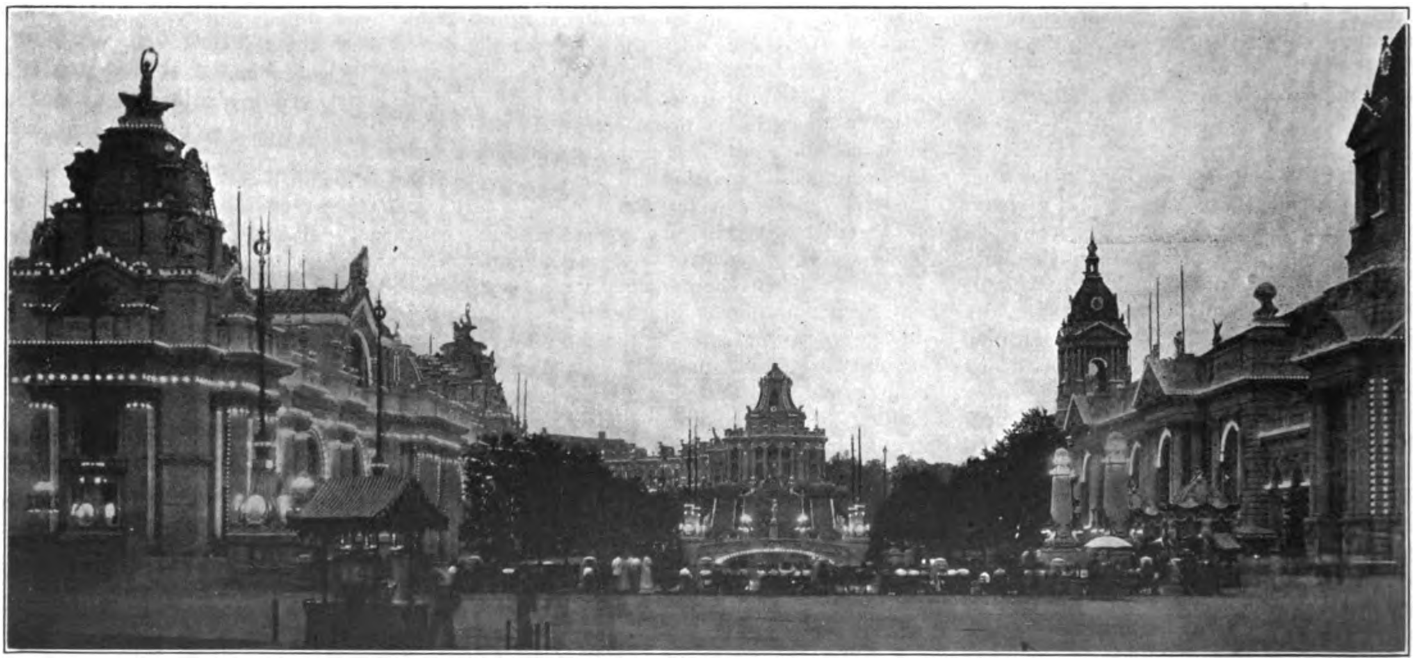

FIG. 4.—TWILIGHT VIEW FROM THE PLAZA OF ST. ANTHONY.

On either side of Festival Hall, Fig. 1, are the Colonnades, which are also plentifully supplied with light. Much of the lighting here is by concealed lamps placed so as to throw light on the columns from behind them and so illuminate the columns without revealing the source of light. The same principle is employed on some of the other buildings rather more effectively.

Festival Hall, the Colonnades and the two pavilions on each end are illuminated by three separate sets of incandescent lights. Each set is of a different color, emerald, ruby and clear bulbs being used. The effect produced by the sudden change in color of the great picture must be seen to be fully appreciated. In wiring the three sets of lamps to permit of their being operated independently, a four-wire system was used, one of the four wires being a common return for the three circuits.

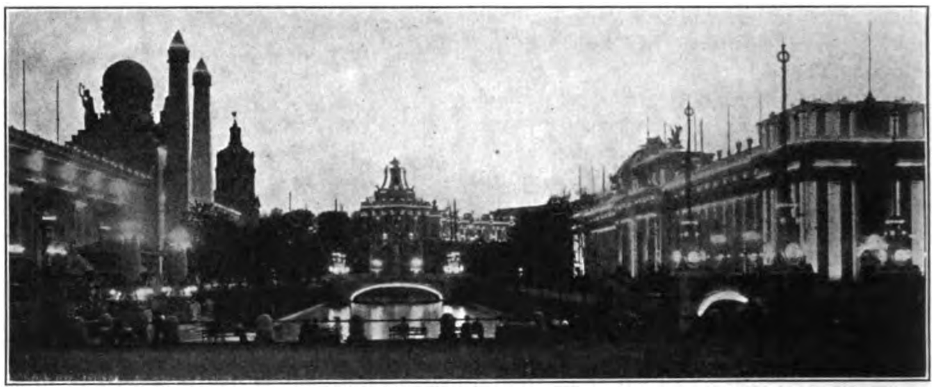

FIG. 5.—TWILIGHT VIEW FROM THE PLAZA OF ORLEANS.

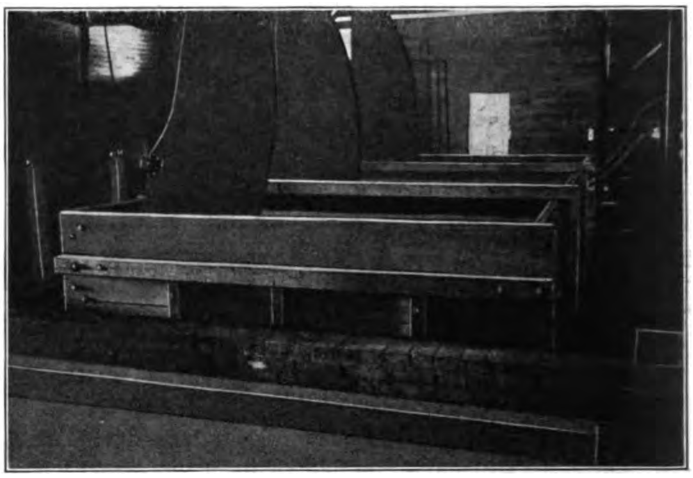

FIG. 3.—WATER RHEOSTAT.

Switchboards for operating the colored lamps are installed under the spillways of both the east and west Cascades, and in order that the two operators may work in harmony a set of signals is used between the two boards. Swivel switches, of the three-pole, three-throw type are employed. Each of the three required is rated at 400 to 500 amperes and 250 volts. Two of these are installed on the switchboard under the east spillway, Fig. 2. Each switch controls certain sections of the main picture.

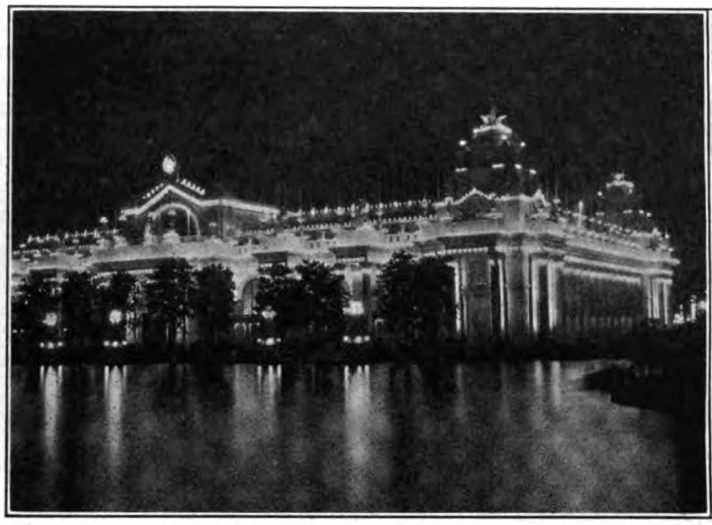

FIG. 6.—PALACE OF ELECTRICITY.

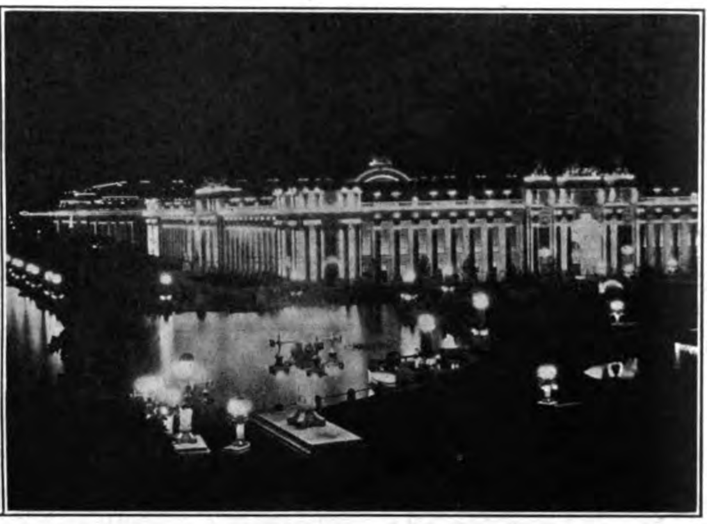

FIG. 7.—PALACE OF EDUCATION.

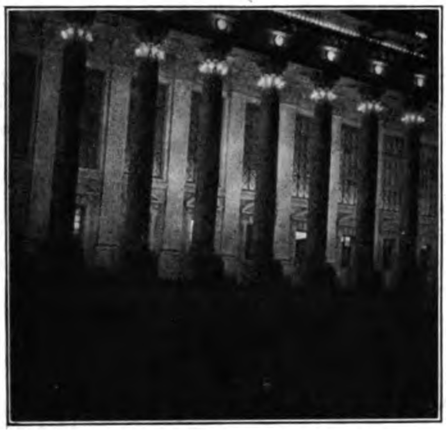

FIG. 8.

When the handles of the switches are thrown up, the clear lamps are lighted; when swung to the left, current is thrown on the emerald lamps; and when swung to the right, the ruby lamps are placed in circuit. At the present time it is customary to alternate the two colored systems with the clear bulbs, these latter being allowed to burn fifteen minues, and the colored lights being limited to five minutes.

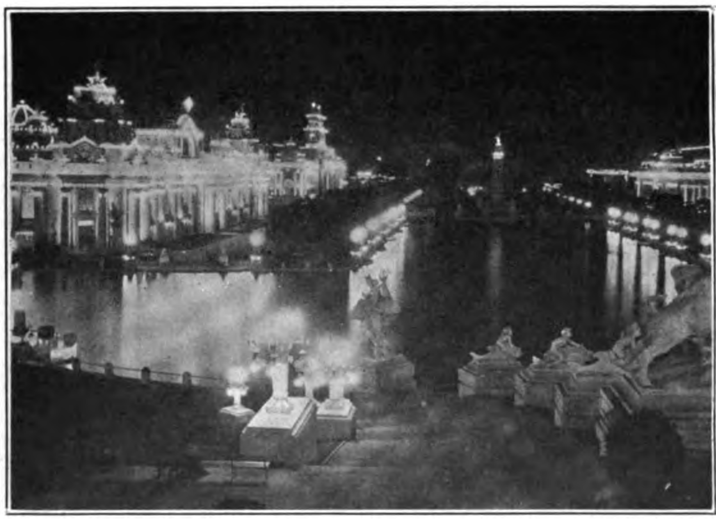

FIG. 10.—ELECTRICITY PALACE FROM THE CASCADES.

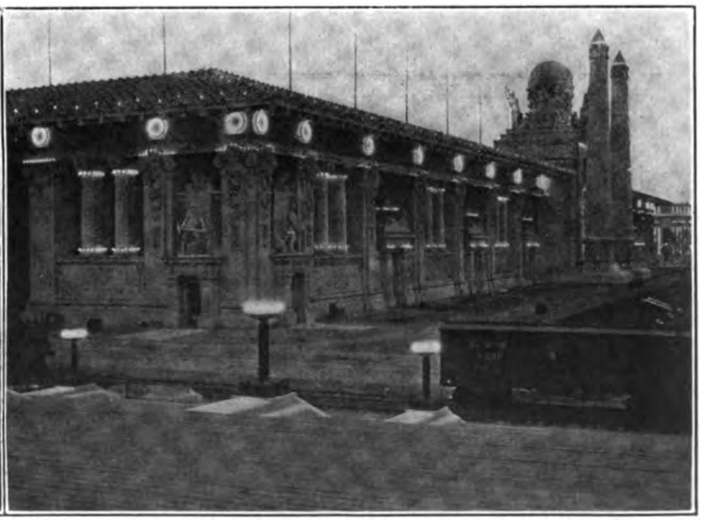

FIG. 11.—TWILIGHT VIEW OF PALACE OF MINES AND METALLURGY.

Resistances are placed in the circuit so that the separate systems of light may be gradually brought up to full candle-power. Water rheostats are placed under the west Cascade. These consist of large wooden tanks filled with water, as shown in Fig. 3, one of the electrodes being placed permanently in the liquid. The movable electrode consists of a flat piece of cast iron of peculiar shape and pivoted at one end; the other may be lowered into the water by means of a windlass, this windlass operating the three electrodes of the three tanks simultaneously, as in the case of the big water rheostat at the Pan-American Exposition.

At either end of the Colonnades are the Pavilions. A view looking from the Plaza of St. Anthony between the Palaces of Machinery and Electricity toward the west Pavilion is shown in Fig. 4. Fig. 5 is a view from the Plaza of Orleans, looking between the Palaces of Mines and Education toward the east Pavilion. These two latter views were taken at twilight, which is thought by many to be the most pleasing time to view the illumination, as at that time the details of the architecture are visible with their beauty enhanced by the decoration afforded by the incandescent lamps.

Of all the principal buildings the one most profusely decorated with lights is the Palace of Electricity, Fig. 6, on which sufficient lights have been placed to bring out more of the architectural details than on any other building in the exposition.

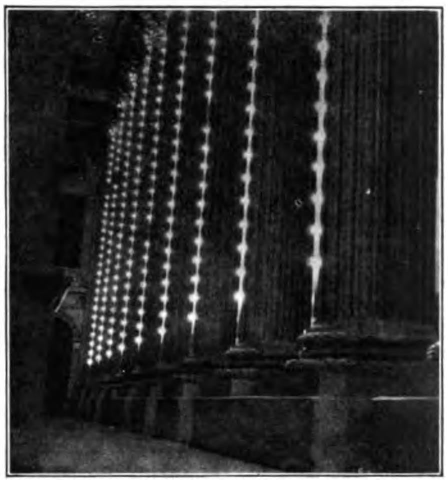

FIG. 9.

Another style of lighting is that shown in Fig. 7, which is a view of the Palace of

Education from the neighborhood of Festival Hall, looking down on the Grand Basin and showing some of the post lighting near the Cascades in the foreground. While it will be noticed that the number of exposed lights on this building is not large, the building is apparently all aglow.

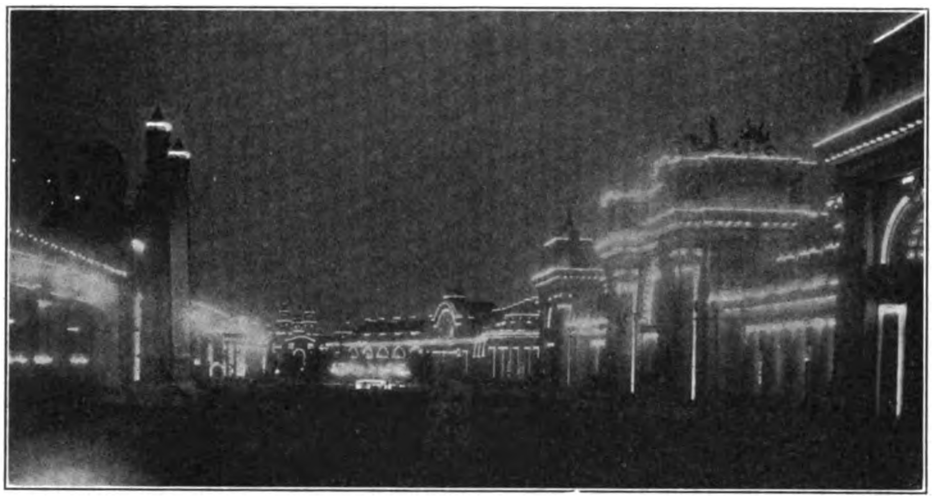

FIG. 12.—VIEW LOOKING WEST FROM GOVERNMENT BUILDING.

This effect is secured on this and a number of other buildings by the use of rows of lamps hidden behind the columns and casting their lights against the white sides of the building. A nearer view of the side of a building so lighted is shown in Fig. 8. How the effect is produced is shown in Fig. 9, which is a view taken behind the columns. Another grand view from the Cascades is that looking down on the Palace of Electricity, Fig. 10.

The Palace of Mines and Metallurgy has a style of architecture distinctly different from the other large exposition buildings. Being one of the less prominent, it was not wise or feasible to embellish it as lavishly as some of the other buildings, but the simple lighting decoration shown in the twilight view, illustrated in Fig. 11, is not without admirers. The Palace of Machinery, shown in Fig. 4, is also a building that has given pleasing effects with very simple treatment and a comparatively small number of lamps. In this case there is no attempt to bring out detail of architecture, but the building has been decorated with plain rows of lights. Fig. 12 is a view looking west from the Government Building, with the Palace of Liberal Arts on the right, the Palace of Mines and Metallurgy on the left, and the Palace of Manufactures in the background. This is a characteristic view, and a number of such are available along the long curved which are remarkably effective, and others court or avenue facing which all the larger exposition buildings are located.

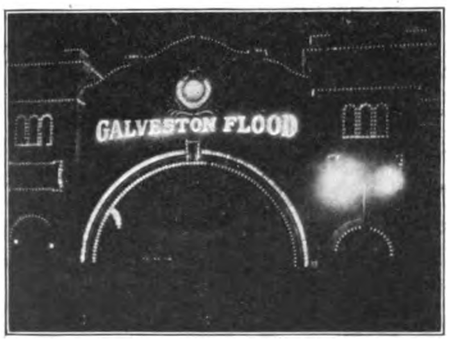

FIG. 13.—GALVESTON FLOOD.

The exposition offers an excellent opportunity for the electrical engineer to study the effects of different designs of electric signs. The "Pike" is lined with electric signs from one end to the other, some of are striking examples of "how not to do it." In general, it can be said that the electric signs which are most successful are those which are most easily read and which stand out clean-cut and distinct. One good example is that in front of the "Galveston Flood," Fig. 13; another is "Under and Over the Sea," Fg. 14. Both of these signs employ lamps of low candle-power and a form of lettering which does not blur one part of a letter into another when the letter is seen from a distance at night. In contrast to these signs are the ones employed at the Intramural stations, Fig. 15. Sixteen candle-power lamps are used in these signs and the letters are of such a design that a person standing some distance away, or not directly in front of the sign, cannot read the sign at all, but sees only a blur of light. Another form of electric sign is that at the terminal station of the Wabash Railroad at the Exposition Grounds, Fig. 16; this can be read at a great distance, although the intensity of the light from the sign is very low, the lamps themselves being hidden. The light comes through perforations in the face of the sign. Electric light is very effectively used for advertisement and decoration on the attraction called "New York to the North Pole," Fig. 17. This building is made to stand out at night by incandescent lamps scattered over its surface and also has a very effective electric sign. The attempt to outline the ship's rigging will hardly be called a success, however, until it is carried out further so as to outline more of the rigging.

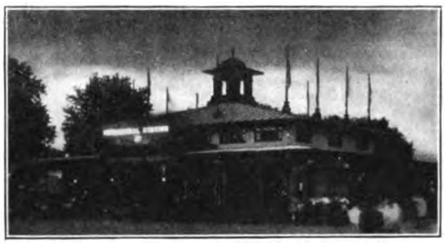

FIG. 15.—INTRAMURAL STATION.

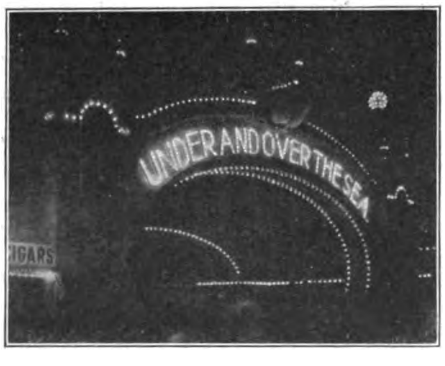

FIG. 14.—UNDER AND OVER THE SEA.

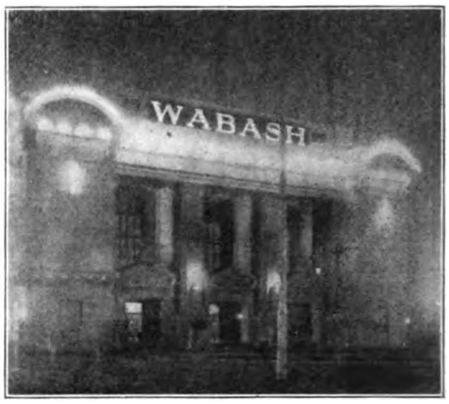

FIG. 16.—WABASH TERMINAL.

The decorative lights of the exposition are 8 candle-power, 110-volt lamps, run on a four-wire system of distribution. The circuits are supplied from transformers located at sub-stations in each of the principal buildings. These transformers are supplied with 6600-volt, three-phase, 60-cycle alternating current from the Exposition power plant in the Palace of Machinery. A separate feeder is run to each sub-station and the decorative lighting is kept independent of the other load at the switchboard. Ordinarily the lighting load is carried by the 3500-kw. Allis-Chalmers-Bullock unit. The lights are turned on at twilight, being brought up to brilliance slowly by gradually exciting the fields of the generator. The load takes about the full capacity of this generator. The bringing of the lights up to full brilliancy gradually is not only desirable from an engineering standpoint, because it avoids throwing a large load on the generator suddenly, but is very impressive from a spectacular standpoint, the turning on of the decorative lights being one of the great daily events of the exposition that is watched for by thousands.

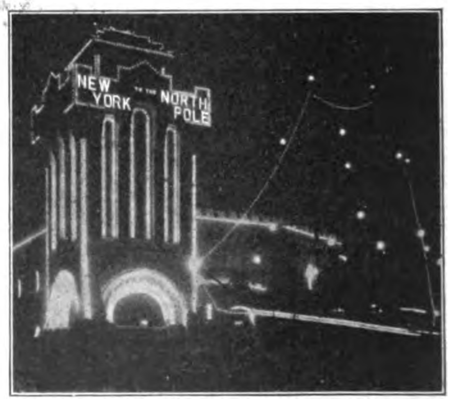

FIG. 17.—NEW YORK TO THE NORTH POLE.

LARGEST STEAM-DRIVEN POWER STATION IN THE WORLD

STEAM PLANT OF THE NEW YORK INTERBOROUGH RAPID TRANSIT COMPANY.

With an insert.

An epoch will be made in the development of the central power plant for the generation and distribution of electrical energy in the approaching completion of the Fifty-ninth Street power plant of the Interborough Rapid Transit Company in New York City, for operating the trains of the new Rapid Transit Subway. Some conception of the magnitude of this plant may be gained when it is considered that this will be the sole source of power supply for the operation of about 800 trains under close headway on 13 miles of three and four-track line. Added interest is aroused by the fact that steam turbines will be used in addition to large reciprocating engines and that these large engines of 8000 horse-power capacity each will be equipped with poppet valves for use with superheated steam.

The building has a frontage on Eleventh Avenue of 200 feet and will have a depth along Fifty-eight and Fifty-ninth Streets of about 700 feet, ending with a brick wall of a semi-temporary nature which will be removed in the event of the building being extended. It is of skeleton steel construction; the side walls, of brick, terra cotta and granite, are self-supporting and are built independent of the steel work.

In arrangement the building does not differ materially from that of the larger power plants, with which the reader is doubtless familiar and which have come to be accepted as the most approved design. It is separated transversely into practically two distinct buildings, the boiler house on the south side and the engine house on the north, by a heavy brick division wall which extends from the basement to the roof. The engine room is divided into three bays, the center or main bay being the operating room and contains the prime-movers; this bay is balanced by the steam pipe area on the south and galleries on the north. In the steam pipe area are placed all boiler feed pumps, dry vacuum pumps, circulating water pumps, main steam pipes with their manifolds, and the equalizing line; the exhaust pipe to the atmosphere also passes through this part of the building to the roof. Commencing at the floor on which the main steam pipes enter from the boiler house, this "area" is separated from the main operating room by a brick enclosure wall which will prevent steam entering the operating room in the event of a steam pipe failing. This wall extends to the second floor above the one on which it starts. The galleries on the north side of the engine house are devoted entirely to electrical equipment.

The engine house is covered by a roof with two pitches, that portion of the roof having the steeper pitch being covered with skylight, the other with slab construction.

The boiler house is laid out with an exceptional degree of economy of floor space, only one floor being devoted to boilers. These extend in two unbroken rows the entire length of the building, this being made possible by the novel scheme of supporting the chimney stacks from a platform located about on a level with the roof. Above the boiler floor is the economizer floor, which is devoted to smoke flues and economizers with a coal distributing conveyor system. The coal bunkers are so located that the hoppers open directly over this floor. The boiler house is covered with a main roof with a monitor. Longitudinally the building has been divided into sections or bays, and with the exception of the turbine bay, each is an exact duplicate of the other. Each will consist of a generating set, the necessary boilers to supply the steam, its boiler feed pumps, circulating water pumps and dry vacuum pumps; the only features making them at all interdependent are the chimney stacks and the discharge from the hot wells, one of each being provided for two sections or bays.

The interior of the operating room will be furnished around the side walls with a cream-colored enamel brick wainscotting, carried to a point about 7 feet above the floor, and will have a molded cap and base. Above this wainscott all the interior walls that are exposed to view will be finished with a face brick of a light buff color.

The steel work is of an extremely massive design, so much so that it may be classed in bridge work. The floors generally consist of I-beams and plate girders, the girders being as a rule placed 3 inches below the finished floor level and the connecting beams from 1½ to 2 inches below that, depending on the thickness of the girder flange, thus avoiding the necessity of coping. Where the floor beams connect to girders, they rest on a specially designed seat which is riveted to the web of the girder. The beams are riveted to this seat, and in addition have a side angle or "knee" riveted to the web, which rivets to the web of the girder. Where beams or girders connect to the faces of columns a similar seat is used, but instead of using a side angle a clip angle is provided, which rivets to the top flange of the beam or girder and to the face of the column. These seats were designed to carry a load greater than one-half the maximum carrying capacity of the beams for which they were intended, and sufficient rivets in single shear were provided to take care of that load.

The columns, with the exception of the wall columns and those carrying the stack, which are of plates and angles, are of plates and channels, the channels being 12 inches deep and the plates 18 inches wide. The channels and plates vary in section, depending on the load that the column carries. The wall columns up to the third tier are of the box type of plate and angle construction, and are 18 inches x 24 inches outside dimensions; above the third tier they are of 12-in. channels and 16-in. plates

As the main operating room in the engine house is 78 feet wide between the center lines of the columns, there is a stretch of wall of that distance across the ends, which must be protected against wind pressure. This has been done by using two plate girder columns 42 inches deep, with flanges 13 inches wide, anchored to foundations at the bottom and to a plate girder, with its web horizontal, at the roof line. At two points between, where floors occur, additional provision is made by means of latticed girders placed with the webs horizontal and connected to the floor system and these columns.

The method of supporting the crane girders deserves particular mention as it is simple and extremely effective. In order to provide the necessary clearances for the crane, and to avoid the excessive bending moment on the columns attendant thereto, the idea of using cantilevers to support the girders was developed very successfully. These cantilevers are of angles latticed, with a web plate and reinforcing plate extending from the supporting column to the crane girder. They are riveted directly onto the face of the columns, one on each side of each column, thereby bringing the load from the crane directly concentric on the column. The small uplift from the cantilever is provided against by their outer ends being connected to the columns in the next longitudinal row. The reinforcing plate was made necessary by the excessive shear that was brought on the cantilever where they connected to the supporting columns.

The roof trusses over the engine house are supported by the crane supporting columns, which are carried up to the proper height for that purpose, and the trusses span 78 feet from center line to center line of the columns. Lattice purlins span from truss to truss and support the I-beam, rafters, and the skylight bars.

The roof over the boiler house consists of a main roof with a monitor. The main roof trusses are supported upon columns which are independent of the building columns, and the monitor trusses come directly over the main roof trusses.

The coal bunkers are of heavy I-beam and plate-girder construction, the bottom being formed of three plate girders, one horizontal and two inclined at an angle of 45 degrees, the beams being riveted to the top flange. The end bulkheads are of 15-in. I-beams placed vertical, the bottoms being connected to the horizontal and inclined girders; the tops are riveted to heavy plate girders 42 inches deep which are placed with their webs in a horizontal position, thus providing against the thrust due to the immense body of coal in the bunkers; along each side of the bunkers and at such a level that the girders just described are riveted thereto is a girder of T section, the top consisting of a plate 24 inches wide with an angle at each edge, the web, or what would be considered the stem of the T, being formed of a plate 30 inches wide and four angles. The arrangement of these girders forms a rectangle in such a manner as to cause the pressure on the four sides to neutralize.

The steel work supporting the chimney stack is very massive and consists of a platform of 24-in. I-beams, directly on which rests the brickwork of the stack; these are supported by a system of plate girders 8 ft. deep. The columns supporting this great weight are of box section of plates and angles and are about 16 x 20 inches.

The foundations offered quite a serious problem, owing to the irregular formation of the bed rock. At the northeast corner of the site, 12 ft. of the rock had to be blasted away in order to get down to the level required, while at the west end rock was not found until 35 ft. below the surface. Cast-iron bases were used to distribute the weight carried by the columns over an area large enough to bring the unit pressure within the limit prescribed by the building laws, and where bed rock was found close up to the bottoms of the bases they were set with a pad of concrete 12 inches thick for leveling purposes.

Where piers were required they were built of concrete of such size as to be perfectly stable and were carried down to bed rock; they were capped with a granite base stone on which the cast-iron base was set. The wall footings are of concrete and are carried down to rock, waterproofing being provided on the external surface carried up to the level of the sidewalks.

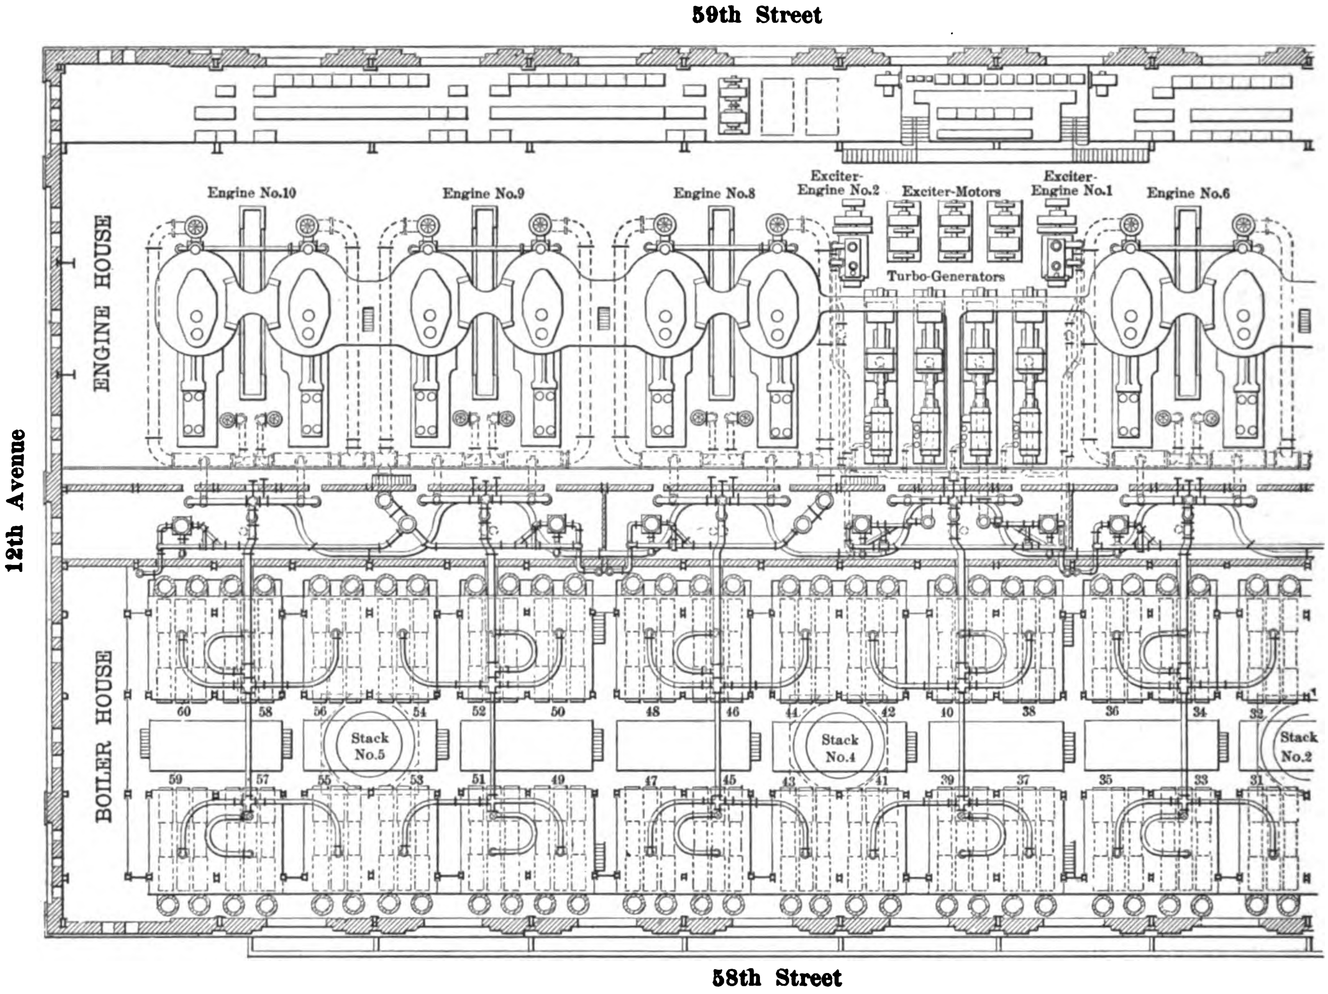

FIG. 1.—PLAN VIEW OF WEST HALF OF INTERBOROUGH RAPID TRANSIT POWER HOUSE.

In order to meet the extreme requirements, the floors were made very strong and are of concrete arches, reinforced with expanded metals, sprung between the floor beams from the bottom flanges, when the beams are of the same depth. When there is a difference in the depth of the beams, or an arch is turned from a beam to a girder, a shelf angle is riveted to the deeper member level with the bottom flange of the shallower one. The tops of these arches are about level with the tops of the beams and their intrados have a rise of about 1½ inches per foot of span; over this is a filling of cinder concrete to within about 2 inches of the finished floor. This 2-inch space is taken up with a granolithic finish which brings the floor up to the proper level. The floor construction is to stand test loads as follows: 200 pounds per square foot on all flat portions of the roof, 500 pounds per square foot in the engine house, and 300 pounds per square foot in the boiler house.

The main boiler house floor is of the masonry arch construction just described, and the uniform load was taken at 300 pounds per square foot. In front of the boilers, where the wear will be greatest, cast-iron checkered plates are located. These plates are three feet wide and extend the full width of a battery, or 30 feet. Directly behind each battery of the row on the north side are gratings of 2½ x ⅜-in. flat steel bars on edge and spaced 1¼ inches from center to center.

In the engine house the floor that corresponds to the level of the main boiler floor just described is on the north side and is devoted to electrical apparatus, as are all the floors on that side of the building. They are of the construction described as to masonry arch work, but have in addition a second floor about 15 inches above the true floor, of slate slabs resting on brick partitions, which form compartments or ducts in which cables are laid. In the south side or pipe area there is a series of platforms at a height convenient to operate the pumps.

About 8 feet above the main boiler house floor is located the main operating floor of the engine room. It is from this floor that all the main engines, exciter engines and turbines will be operated. This is of regular construction and is designed for a uniform load of 500 pounds per square foot. Around each alternator special flooring is provided, so arranged as to be easily removed should occasion arise.

In the boiler house the floor at this level consists of a system of platforms which extend in front and between all boilers and in the rear of the north row of boilers against the division wall. The platforms are perforated cast-iron plates ⅞ inch thick supported on steel I-beams. They are located so that easy access is had from the main operating floor of the engine house through doors in the division wall. These platforms are at such a height with relation to the boilers as to make it convenient to do any work that may be necessary about the boiler tubes, and are a decided advantage over the common method of building a makeshift scaffold when such work is to be done.

The railings around the openings in the various floors and around the galleries, with the exception of the main switchboard galleries and the openings in the main operating floor, are to be of wrought-iron pipe supported by cast-iron stanchions. These stanchions are to be bolted directly to the steelwork, and where cast-iron plates are used for the floor they are fitted around the bases of the stanchions. The railings around the openings in the main operating floor will be of brass tubing in polished steel stanchions, while about the main switchboard galleries the railings are to be of wrought-iron scroll in panels between wrought-iron balusters, with a hand rail of galvanized-iron pipe.

In most boiler installations the tops of the boilers are left about as they happen to be when the workmen finish the setting, no effort being made to provide a convenient platform about the steam pipe connections for the use of workmen who may have occasion to go there. In this plant ample provision for the convenience of working about the tops of the boilers has been made by means of a platform of steel plates reinforced with stiffening angles, which is laid directly on top of the beams supporting the boilers. These platforms are connected with each other by a walkway at the rear of the boilers, extending the entire length of the building. The plates are removable, with a few exceptions, and a perfectly smooth surface is presented, all rivets being countersunk on the exposed side. In the steam pipe area in the engine house, at this level, is located the main steam pipe floor, which is of the concrete construction already described; here are located the steam manifolds, the equalizing line, the feed-water heaters, etc. Communication is had from this floor to the platforms over the boilers by means of doorways which open on to the walkways connected with the platforms.

The economizer floor is located next and is devoted to the smoke flues, economizers and a coal-distributing conveyor. In this floor and over the valves in the main steam header are located gratings of 2-in. x ⅜-in. wrought steel on edge, which may be removed to facilitate working around these valves.

The handling of a quantity of coal of such magnitude as will be necessary for the operation of this plant becomes quite a problem and the solution that is adopted has great interest. The conveyors used throughout, with one exception, are the Robins belt type; the one exception is a scraper conveyor on the economizer floor. The entire handling equipment was furnished and installed by the Robins Conveying Belt Company.

The coal will be received at the Fifty-eighth Street pier in barges and will be unloaded by a tower unloader of a capacity of 125 tons per hour. This unloader is equipped with crushing rollers and weighing machines. After the coal passes through the rolls and weighing machines it is deposited on a belt conveyor operating on the surface of the dock; this in turn dumps the coal on the first of a series of conveyors traveling in a tunnel under the sidewalk of Fifty-eighth Street; this tunnel is sufficiently large to accommodate a second system of conveyors should it be considered necessary. The last conveyor in the tunnel deposits the coal on the first of the elevating conveyors, which will operate in the westerly end of the building. They are inclined at an angle of 22½ degrees from the horizontal and run at a speed of about 375 feet per minute; they are 110 feet from the center line of the tail pulley to the center line of the head pulley. There will be four of these inclined conveying units in tandem; the last one of the series will deliver the coal to either of two parallel conveyors operating longitudinally of the building; these are located directly on the horizontal top chord of the main roof truss at equal distances each side of the center line of the coal bunkers and are equipped with movable unloaders which can be located to unload coal at any point into the bunkers. Each conveyor runs about 10 feet a minute faster than the preceding one, in order to surely clear all coal away. The capacity of these conveyors will be about 200 tons per hour.

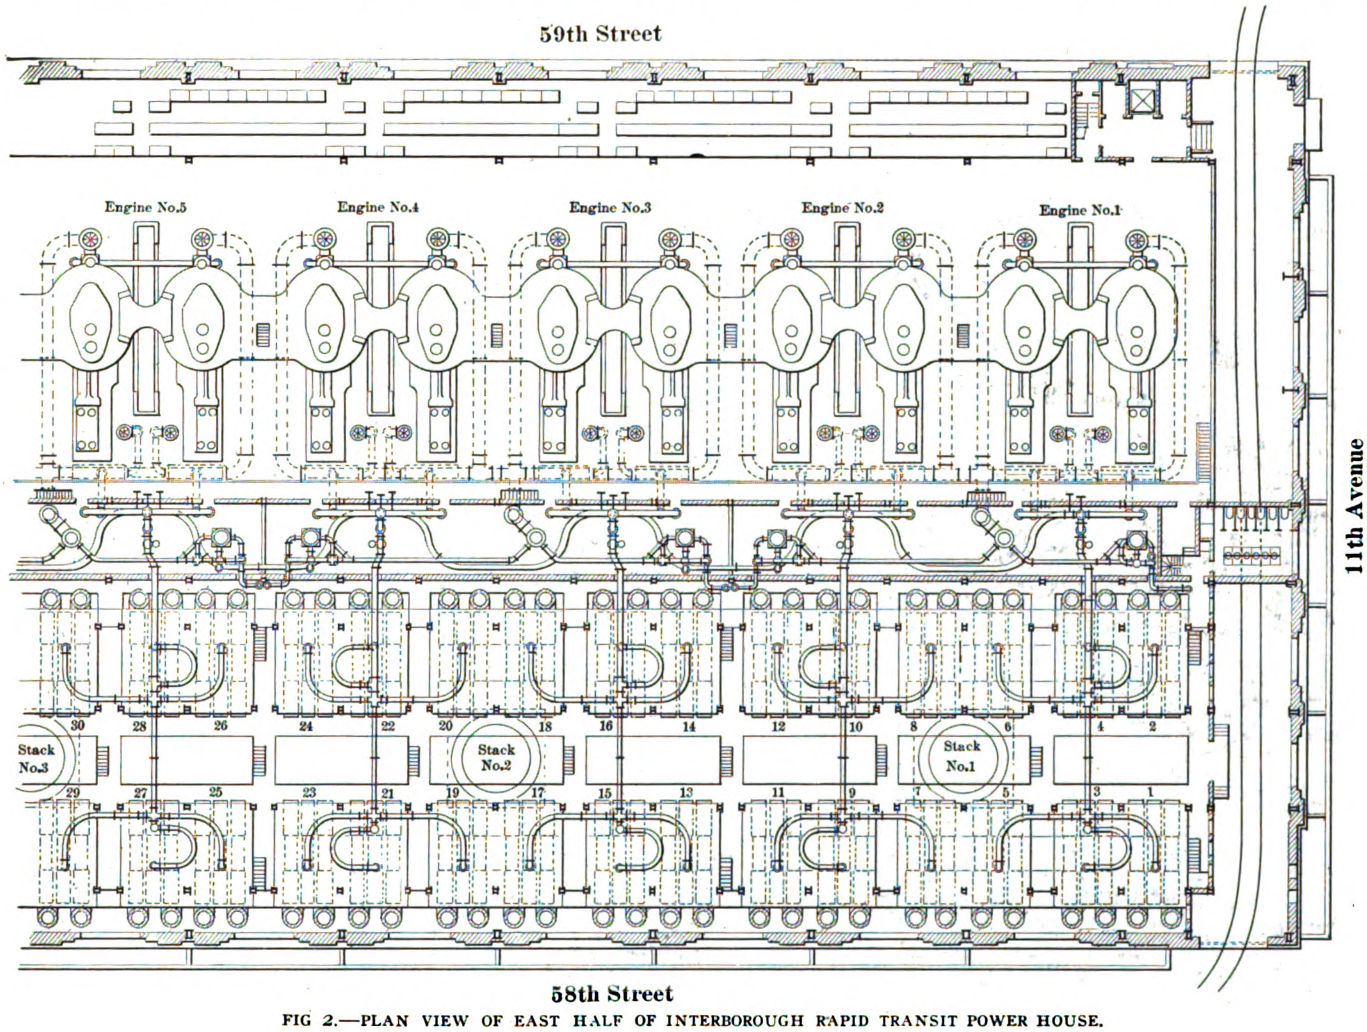

FIG 2.—PLAN VIEW OF EAST HALF OF INTERBOROUGH RAPID TRANSIT POWER HOUSE.

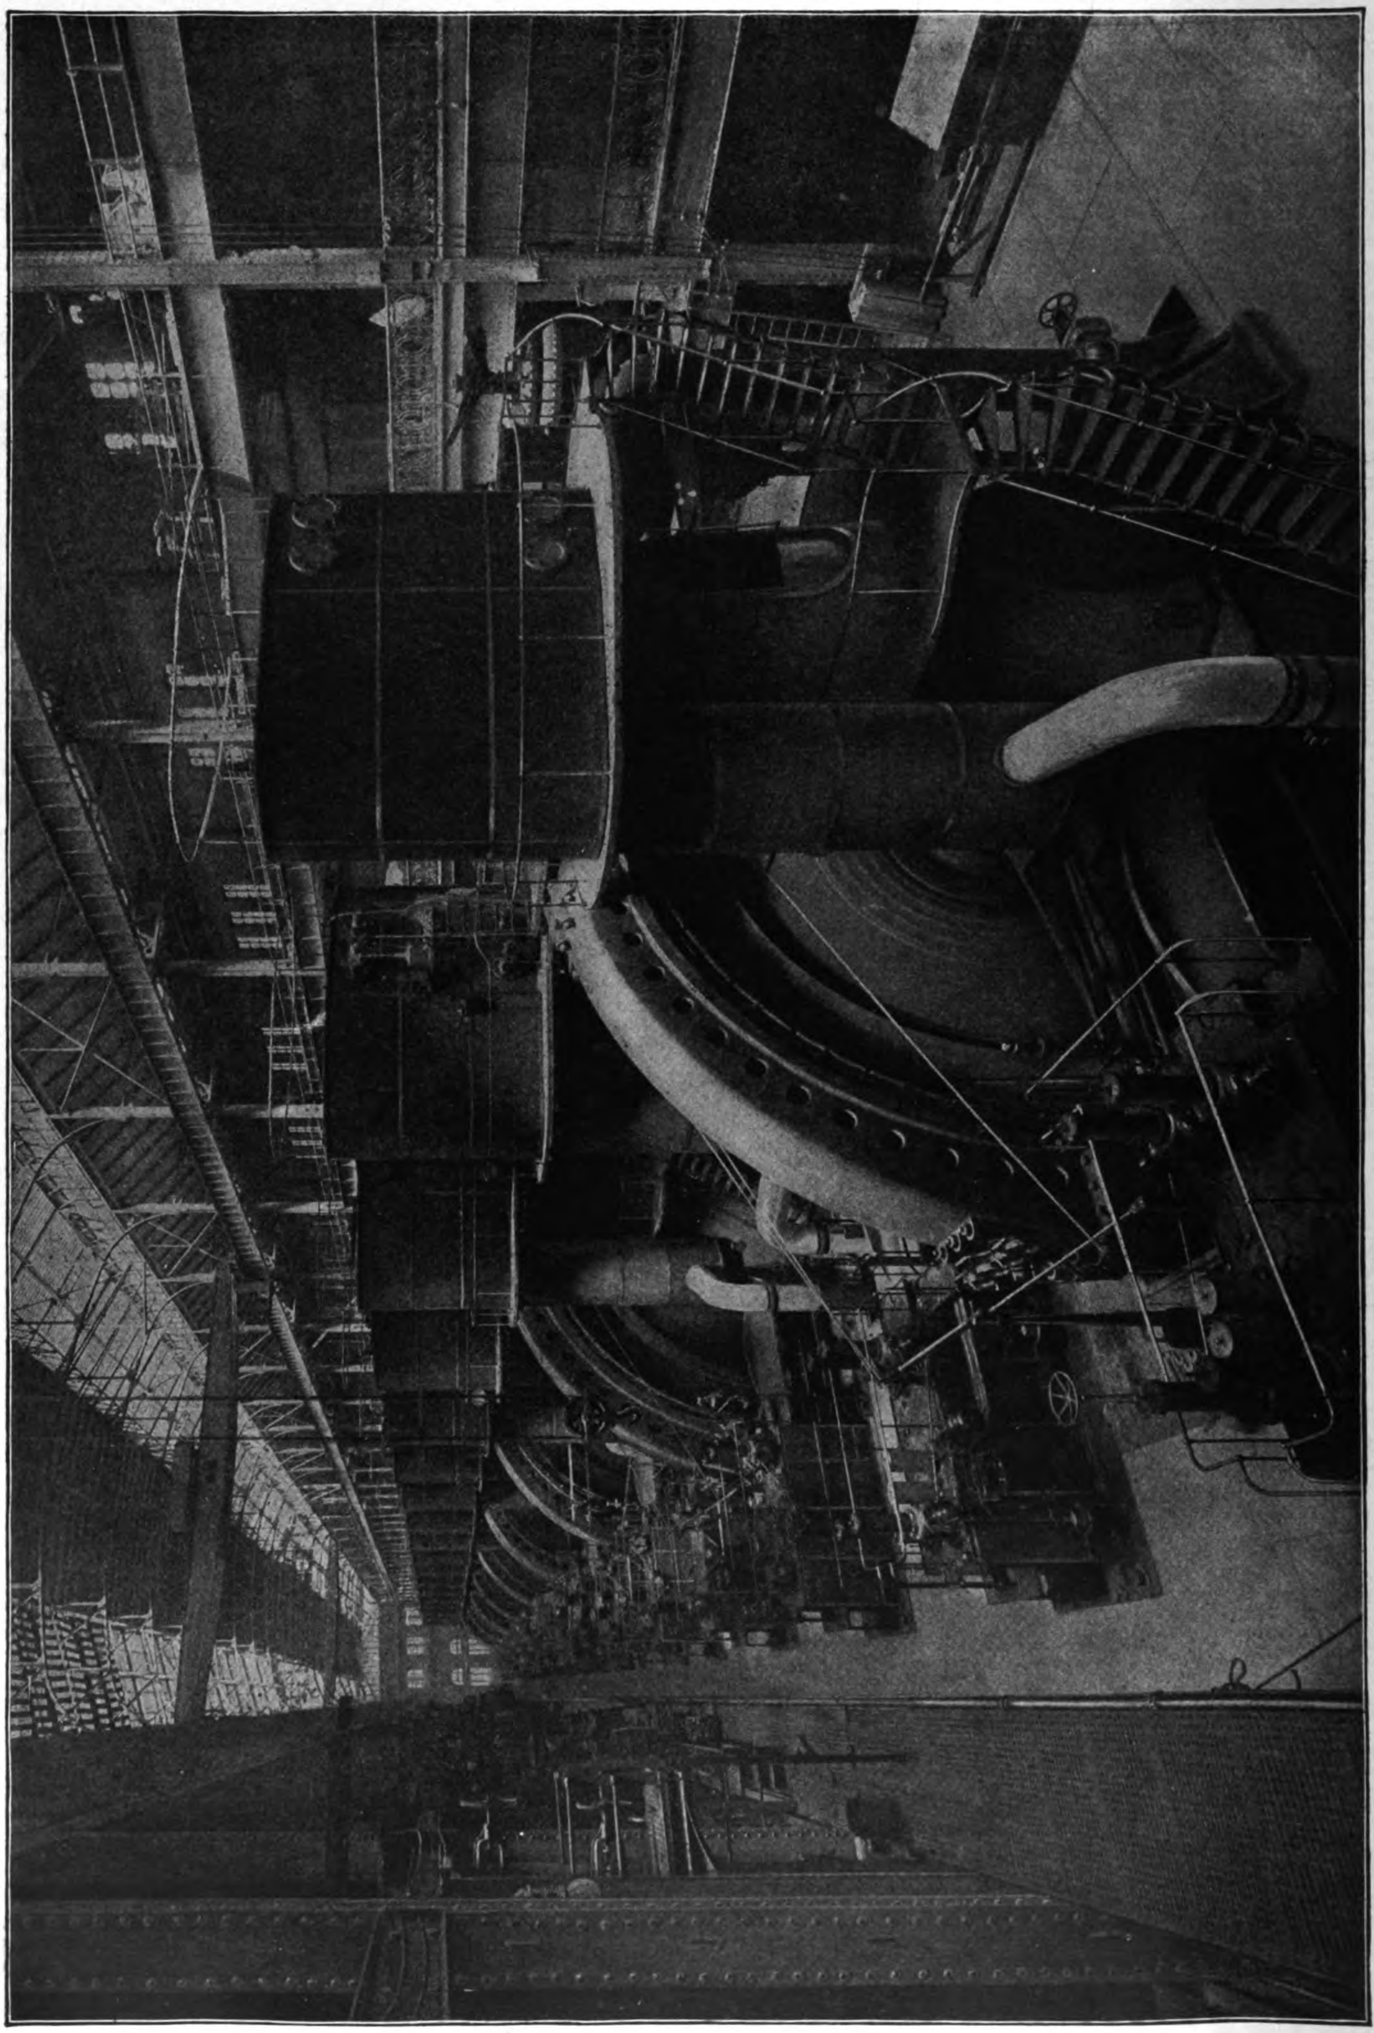

FIG. 3.—OPERATING ROOM OF NEW YORK INTERBOROUGH RAPID TRANSIT POWER HOUSE.

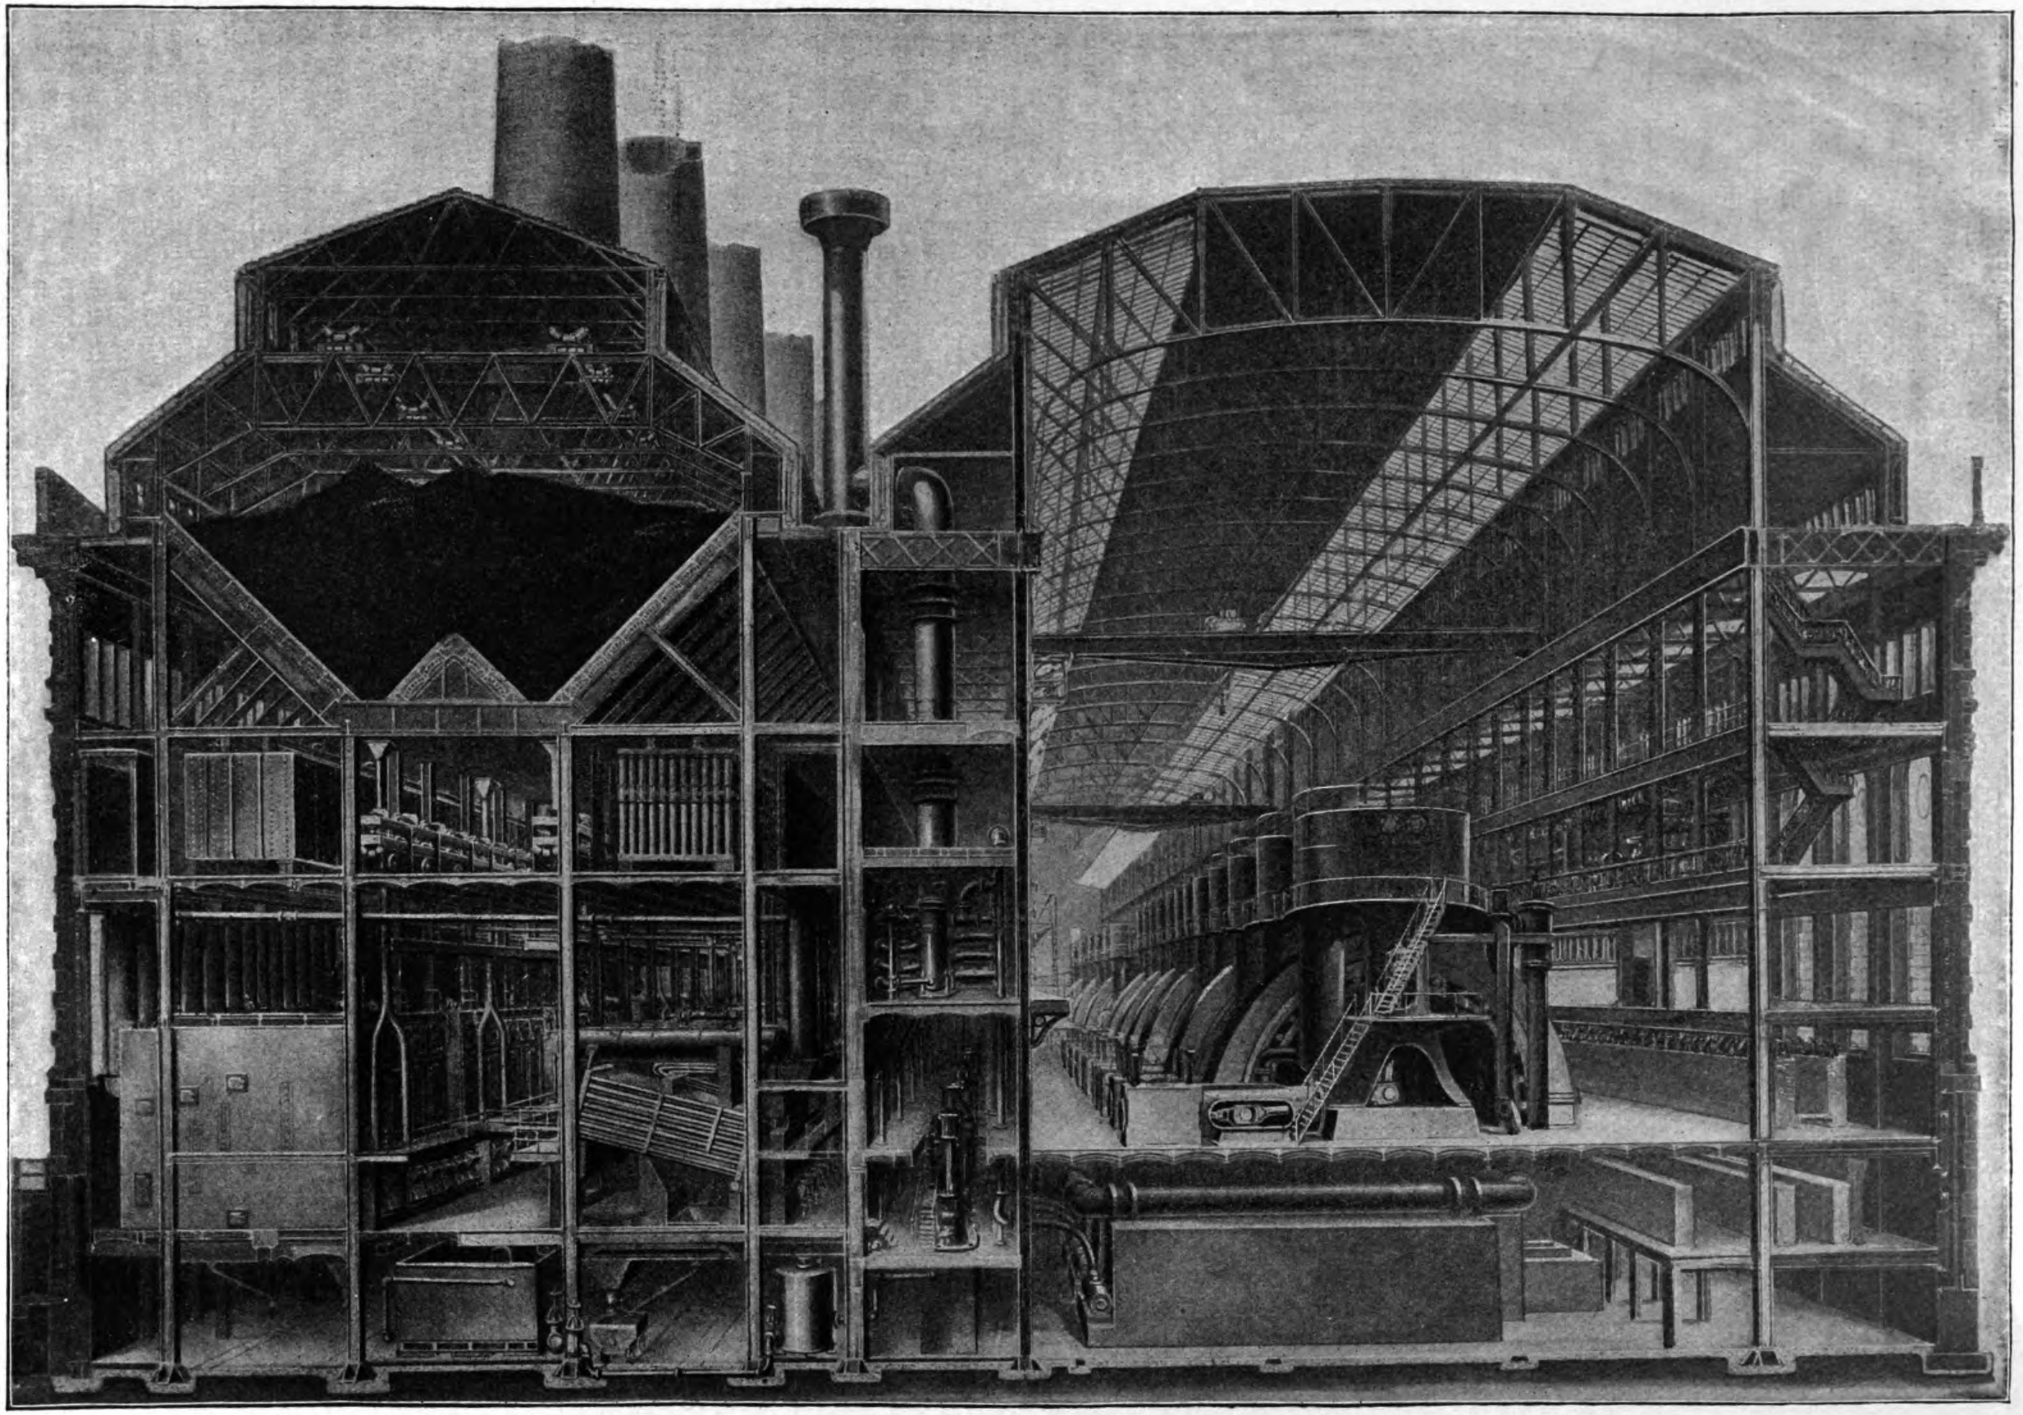

FIG. 4.—COMPLETE VIEW OF THE INTERIOR OF NEW YORK INTERBOROUGH RAPID TRANSIT POWER HOUSE.

The coal after leaving the conveyors is stored in bunkers about 61 feet wide and 80 feet long between the stacks. The sides of the bunkers are inclined at an angle of 45 degrees and bulkheads rise vertically 6 feet above the point where the inclined walls join the vertical ones. There are two rows of cast-iron hoppers in the bottoms of the bunkers located on the center lines about 17 feet apart symmetrical about the longitudinal center line of the bunkers, and 18 feet apart lengthwise of the building. The bottom of each bunker is hoppered at an angle of 45 degrees so as to completely clear itself of coal. The capacity of all the bunkers is estimated to be about 12,000 tons level full, or 16,000 tons if heaped. The bottom, sides and bulkheads are constructed of concrete arches reinforced with expanded metal. The whole surface that is exposed to contact with the coal is faced with a Portland cement body 3 inches thick and a granolithic finish 1 inch thick.

From the bunkers the coal will be delivered through the cast-iron hoppers located in the bottoms into cast-iron pipe chutes, each provided with a gate where it joins the hopper; these chutes deliver the coal into other hoppers located directly on the economizer floor, or into a scraper conveyor operating directly over the said hoppers, which is provided in order to be able to feed coal from any bunker in the building to any set of boilers. As it was necessary to be able to deliver the coal from the chutes into either the conveyor or the hopper, a very ingenious device was made use of; it consists of a bonnet-like affair of cast iron provided with two cut-offs, one opening into the hopper and the other on to the conveyor. From each of these hoppers, which rests on the floor, two more chutes branch off, each leading to the center of the battery of boilers on either side of each hopper, where it again separates into two more chutes which deliver the coal either into the hopper of the stokers or on the cast-iron plate in the boiler room floor directly in front of the firing doors. The entire installation is noticeable for the elimination of manual labor in handling the coal from the coal barges to the furnace.

The ashes after leaving the grate fall into hoppers which are of steel plate reinforced with stiffening angles; the outlets of these hoppers are controlled by gates opened by a lever, which will be operated by hand. Directly under the hoppers an industrial railway is laid for the operation of self-dumping ash cars of 2 tons capacity. These cars are drawn by enclosed electric locomotives. After leaving the basement the cars full of ashes are carried over a hopper and dumped. This hopper feeds to either one of two conveyors, one of which delivers the ashes direct to the loading tower that loads them on scows and the other delivers the ashes to a storage bunker of the Berquist suspension bunker type. This bunker is for storing ashes pending their removal, and has two spouts opening on a belt conveyor which delivers to the loading tower before mentioned. The bunker is to be enclosed with a steel and corrugated-iron

structure above the girders that support it, and is lined on the inside with concrete and expanded metal to protect the steel of which it is made from the ashes. It might be interesting to add that alternating-current motors will be used throughout the entire coal and ash-handling systems.

The steam generating system will consist of 72 boilers and accessories; there will be 144 circular uptakes leading to 24 horizontal flues which, in turn, lead to six chimney stacks. Four units of Green economizers will be installed at first. If it is concluded to equip the entire plant with economizers there will be 24 of these, one at each horizontal flue. There will be nine Worthington boiler feed pumps 12 in. and 17 in. x 8½ in. by 15 in., and ten closed feed-water heaters; six boiler blow-off tanks, and eight storage tanks. In addition to the natural draft from the stacks, provision has been made for forced draft by means of fans. This equipment consists of two engine-driven fans, 7 feet in diameter, for each section of six boilers, the air being delivered beneath the grates.

The boilers used are the Babcock & Wilcox water tube type, of 600 horsepower rating each, having 6,000 square feet of heating surface, 100 square feet of grate surface, and are arranged in batteries of two boilers each. Each boiler consists of three drums, 23 feet 3 inches long and 42 inches in diameter; 294 4-inch tubes, 18 feet long, and is built for 200 pounds pressure. One of the features of these boilers is that of making headers to take 14 layers of tubes, thus obtaining a larger heating surface without having to extend the boilers transversely, or lengthwise of the boiler house; by such careful attention to details the necessity of having two floors of boilers was obviated. The boilers are to have for the main part hand-fired grates, though the settings have been designed to accommodate, with minor changes, any one of four different makes of automatic stokers. Of the first installation of boilers, 36 will be fitted with hand-fired grates and 16 with stokers; 10 will be equipped with superheating coils, 6 to have the B. & W. superheater and 4 to have the Foster superheater. The Foster superheater consists chiefly of parallel rows of straight elements joined at their ends to return headers and manifolds. The straight elements are fitted with concentric cores which confine the steam to thin annular spaces with smooth surfaces through which the steam is passed at high velocity. The exterior of the elements is provided throughout with a series of projecting flanges or gills for increasing the surface in contact with the hot gases and for giving strength. Moreover a great mass of metal is provided which serves as a storage for heat and tends to secure a uniform temperature of steam despite any fluctuation in the heating gases. These boilers are piped up in batteries of six, each battery to supply one engine with steam; two such batteries will be connected to each chimney stack. The boilers equipped with superheaters will be principally used to supply the turbines and are located in the turbine bay.

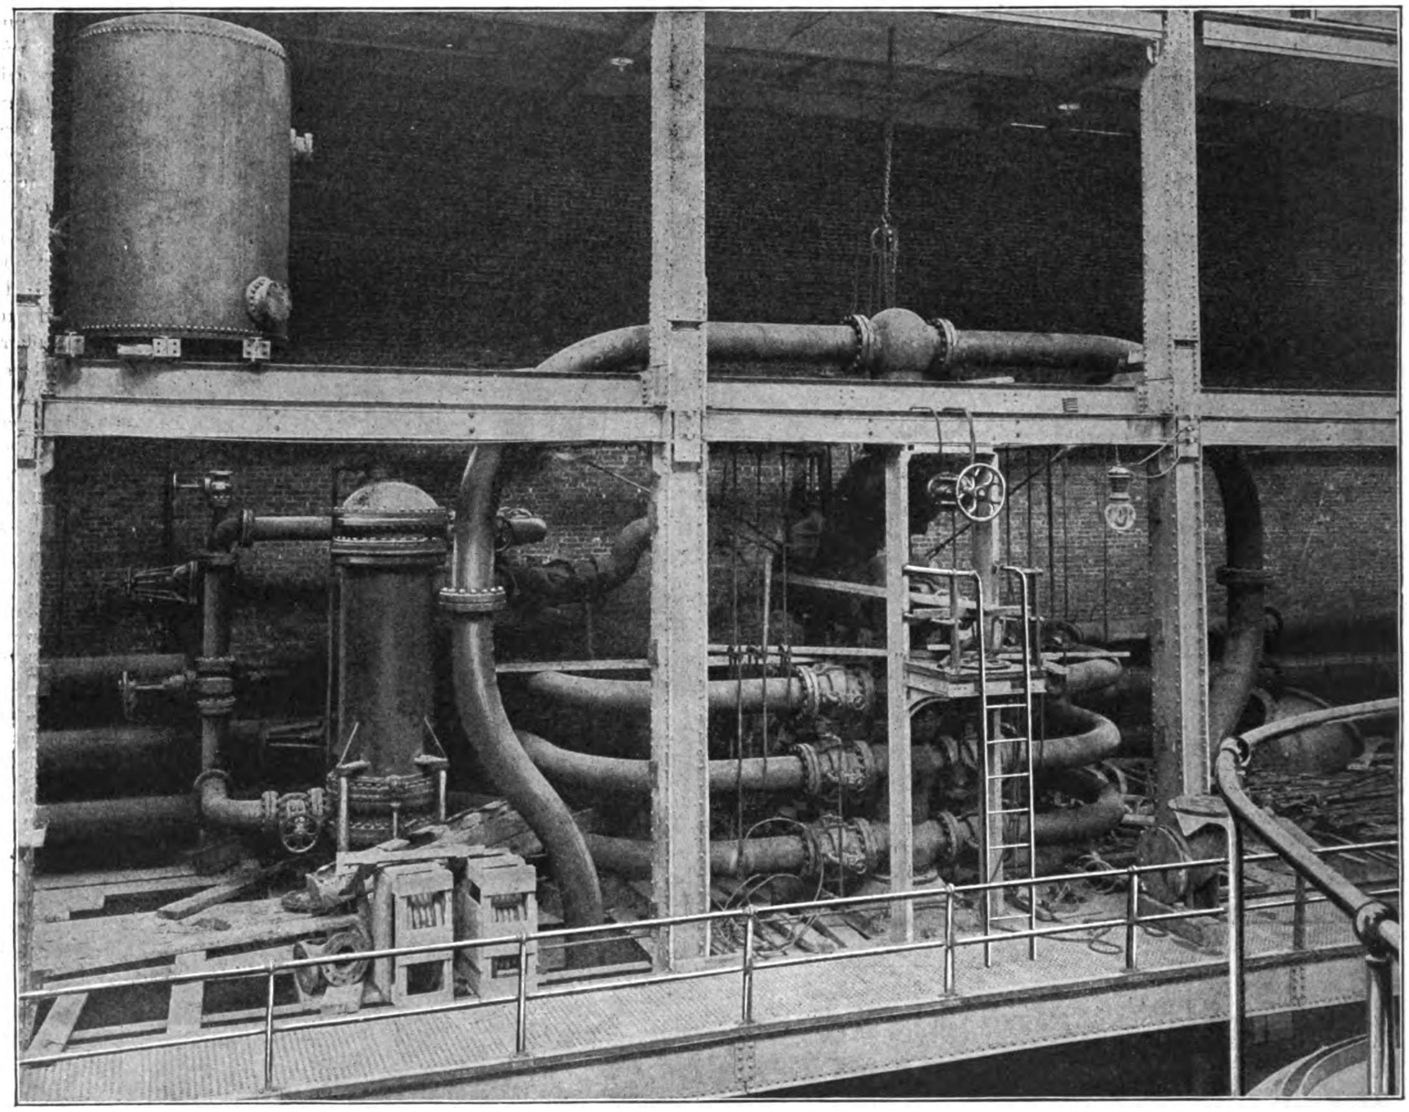

FIG. 7.—PORTION OF MAIN STEAM PIPING IN PIPE AREA.

The feed water is delivered into the boilers from 8-in. feed mains located directly under, and supported from, the main boiler room floor through 3-in. extra heavy seamless brass pipe, which supplies a 2½-in. branch pipe of the same material leading into the boiler drums. Each of these pipes is supplied with a 3-in. gate valve connected directly to the outlet of the main, a 3-in. special straightway disc valve, a 3-in. special check valve, and a 3-in. special angle valve.

The blow-off pipes, of which there are two to each boiler mud drum, are of 2½-in. brass extra strong pipe fitted with a 2½-in. extra strong blow-off valve and an asbestos packed plug cock. These blow-off pipes discharge into a 4-in. header that leads to the blow-off tanks, which are connected to the hot-well discharge trench, and have also an 8-in. vent pipe discharging into the 12-in. exhaust pipe from the pumps to the heaters.

At the rear of each boiler, two flues or uptakes 3½ feet in diameter connect the boiler to the horizontal flue or smoke duct 6 feet 4 inches x 13 feet 2 inches, located on the economizer floor; this smoke duct forms a header for the uptakes of three boilers. Four of these ducts connect to each chimney, two on a side, by means of a specially designed Y-section which combines the two flues and leads into the portal of the stack. These horizontal flues, while usually independent, may be made continuous from one chimney to the next, but cannot be made to pass by a chimney. The circular uptakes and the horizontal flues as far as the combining uptake are lined with a superior quality of red brick. The circular uptakes are provided with dampers at a convenient height to be reached from the platform over the boilers. In order to provide for the movement caused by the difference in temperature, a very ingenious expansion joint was devised; this consists of a cup formed at the top of the uptake by means of a Z casting bolted to the body of the uptake, the recess thus formed being filled with sand. The upper part of the uptake enters this sand-filled cup and an effectual joint is thereby made.

The six chimneys are of the Alphons-Custodis construction, and each will have an inside diameter of 15 feet and a height of 225 feet above the level of the grates. The walls are 24 inches thick at the base and reduce by 2-in. steps about 16 feet apart to 8⅝ inches thick at the top. A baffle wall 21 feet high is built to prevent the gases from one flue interfering with the gases from the one entering at the opposite side. These stacks are estimated to weigh 1160 tons.

The piping systems are the result of much study to determine the best solution of the problem presented. It has been the aim of the designers to arrange all valves, fittings, etc., in such a relation about the center line of each section that a person familiar with any one section will be able to go to any other section and find a given valve in the same relative position.

That part of the boiler feed water piping from the mains to the boiler feed pumps is low pressure; so is the drip piping from the traps to the drip and surge tanks. The boiler feed water piping from the pumps to the boilers, and the drip piping from the steam mains and cylinders to the traps, is high pressure.

In designing the steam piping system, the ordinary routine has been radically departed from and a distinctly new and interesting scheme has been worked out. In the system adopted the steam header idea has been to a certain extent embodied, but in such a way as to lose itself and a peculiarly new arrangement resulted. It would appear that the work was carried out with the idea to construct, as nearly as would be advisable or logical, a succession of individual plants each complete in itself and connected, as one would say, by electric batteries, in multiple with its neighbor by means of what is called the equalizing line, which can serve the purpose to a certain limited degree of a steam header. The plant can be operated, however, without steam being admitted into this equalizing line at any time unless it becomes necessary to operate an engine unit by steam from any battery of boilers other than its own.

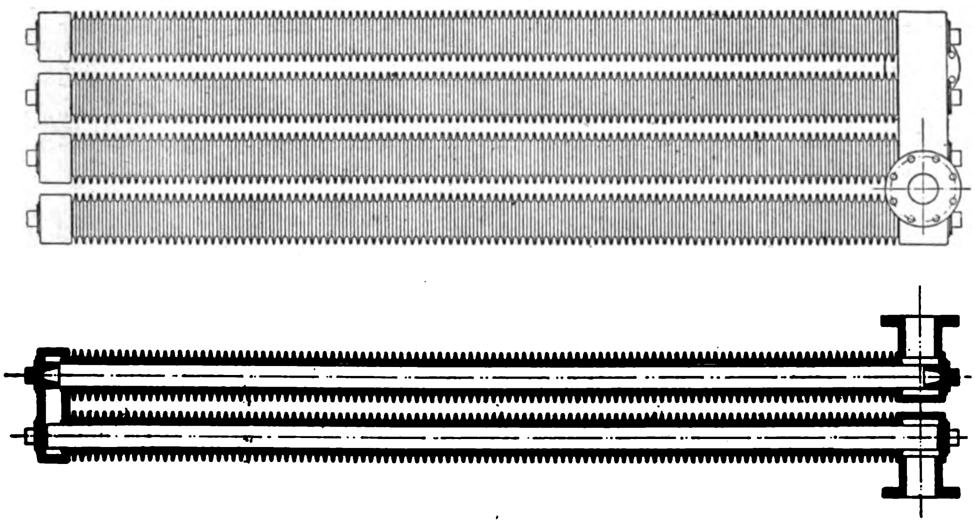

FIG. 8.—SECTION OF FOSTER SUPERHEATER.

It will be noted by reference to the illustrations that equalizing lines of pipe connect the various batteries of boilers; the pipe lines from the individual batteries, which are referred to as main steam headers, terminate at manifolds and these manifolds are connected by the equalizing pipe lines just mentioned. In case it becomes necessary to cross-connect the boiler batteries and the generating units, instead of operating each engine from the battery of boilers corresponding to it, steam from the battery of boilers that is to be cross-connected is delivered through its main steam header into the manifold and there diverted, by means of suitable valves, up or down the building to the point where it is led off to the generating unit. By means of the manifolds alluded to it is possible that the steam from a battery of boilers may be used in the engine unit belonging to this particular battery while steam being used under the conditions just stated is passing through the manifold of the battery in question. The main steam header extends in a perfectly straight line directly over the middle drums of the center boiler of each battery; it starts from a 9-in. x 14-in. x 9-in. cross located over the boilers in the row on the south side of the boiler house, and passes over the north row, where it is increased to a 17-in. pipe. It enters the pipe area through the division wall and is offset 1 foot 2½ inches to bring the manifold in alignment with the center line of the generator. The boilers are connected to the header through 9-in. pipe bends curved to a generous radius between the boiler nozzle and the header and lying in a horizontal plane. Directly over this nozzle the first valve is located; this is an angle valve and opens into a 9-in x 9-in. x 9-in. tee; the straightway of this tee lies in a horizontal position with the branch vertical, and where no superheaters are now used the end away from the valve is covered by a blank flange. Where superheaters are used, the blank flange is removed from the tee and they are connected thereto through a 9-in. angle valve. Fixed in the riser over this tee is a quick-closing 9-in. valve provided with the necessary appliances so that it can be closed from the platform between the boilers. Above this valve is an elbow to which the curved pipe is connected; where this 9-in. curved pipe connects to the header there is another 9-in. valve provided, and by means of elbows these connecting pipes all connect to the headers through the 9-in. x 14-in. x 9-in. cross, thus entering the headers at the side. The 9-in. valves next to the header are all operated from the platform over the boilers by an operating spindle. This description is of the conditions at the row on the south side of the building. At the row on the north side the connections are made to the 17-in. header through a 9-in. x 14-in. x 17-in. cross and a 17-in. x 9-in. tee; with this exception there is no other difference.

Connected to the offset in the header, just after it passes into the pipe area, is a 17-in. gate valve; next a 17-in. x 17-in. tee with the branch looking up. This tee connects to the manifold through a 17-in. special quick-closing balanced angle valve. A 17-in. elbow is connected to the branch of the 17-in. x 17-in. tee, which connects in turn with another special valve and then into a 17-in. x 14-in. x 14-in. cross, located above the special quick-closing angle valve. From each side of this cross there is provided a 14-in. bend of generous radius, in a vertical plane, for the steam supply to each high-pressure cylinder; below this bend is a 14-in. downtake resting on a special elbow, which is provided with a proper support. There is another bend, also in a vertical plane, to each receiver and separator, which it enters at the top. The receivers rest in a horizontal position on the engine foundation; they are well provided with traps. From each receiver to the throttle there is another 14-in. bend, also in a vertical plane, leaving the receiver from the end and connecting to a butterfly valve fitted with a safety stop device.

The main steam piping is of the best quality of wrought-iron or steel lap-welded pipe, provided with a welded flange with a loose wrought flange back of it. For 14-in. and 17-in. pipe and for all pipes between 7 inches and 14 inches, the Van Stone flange is used; on pipes under 7 inches, screwed flanges are used. On pipes over 5 inches in diameter, the flanges have raised seats with ground joints; this means that the joints must be absolutely steam tight.

The boiler feed-water supply may be taken directly from the supply mains or from the storage tanks through an 8-in. branch suction pipe. The water is forced by the pumps through an 8-in. delivery pipe to the feed-water heaters; directly after leaving the pumps, the delivery pipe is furnished with a water relief valve. The piping to the heaters is so equipped with valves that the heaters may be by-passed. From the heaters the piping is carried down into the basement by means of vertical risers, where the system becomes a complete loop lying between the rows of boilers and supported from the boiler floor system. This loop is provided with bends of large radius. There are located at the proper points tees to connect with the brass pipes that feed the boilers and were described with the boilers.

Drip Piping.—All drip pipes from the valves and fittings of the main steam pipes and steam pipes to the auxiliaries are led to the storage tanks, which are located in the feed-water system and help to heat the feed water. From the lower water boxes of feed-water heaters, the steam chamber and the relief valves situated in the atmospheric exhaust and the exhaust from the auxiliaries, drip pipes are carried to an exhaust drain tank, of which there will be provided one for each main engine and one for the turbo-generator set. These exhaust drain tanks connect to suitable pumps which force the water of condensation, which is full of oil, to settling tanks located on the flat roof between the boiler house and engine house. The settling tanks are circular, 48 inches in diameter by about 94 feet long. Here the oil is expected to separate from the water and rise to the surface, whence it is to be removed; the water is to be used for various purposes, such as wetting down ashes, etc.

The water supply system or service piping will make connections with a 12-in. city main at Eleventh Avenue and to a 6-in. main on Fifty-eighth Street and another on Fifty-ninth Street. There will be five 6-in. water meters at the easterly end, connecting with the 12-in. main, and two 6-in. meters at the westerly end; also 3-in. branch meters connecting the plumbing fixtures in the building at eight points along the 12-in. main, between the two groups of 6-in. meters. Connections will be made with eight main storage tanks, each having a capacity of 38,640 cubic feet. Each tank has a 4-in. overflow pipe discharging into the hotwell discharge trench. In case it becomes necessary to use river water, ample provision to do so has been made by means of a salt water pump with a 12-in. suction from a suction well which will be always flooded.

The exhaust piping from the main engines starts from the condensers with a 30-in. relief valve; from this valve the pipe, which is 30 inches in diameter, drops straight down through the main operating floor into the basement, where the exhausts from two units unite into one 48-in. riser which is carried to the roof and terminates in an exhaust head 8 feet in diameter and about 3 feet high. The exhaust pipe is of riveted steel, and is provided with corrugated copper expansion joints. This exhaust pipe has no connection with any feed-water heater. The exhausts from the main steam auxiliaries are combined in 12-in. mains in which the feed-water heaters are inserted; the heaters are by-passed. After leaving the feed-water heater, these exhaust mains connect with the 48-in. main exhaust risers. The exhaust pipe from the turbines extends from the surface condensers with which the turbines are equipped through the basement and thence directly to the roof.

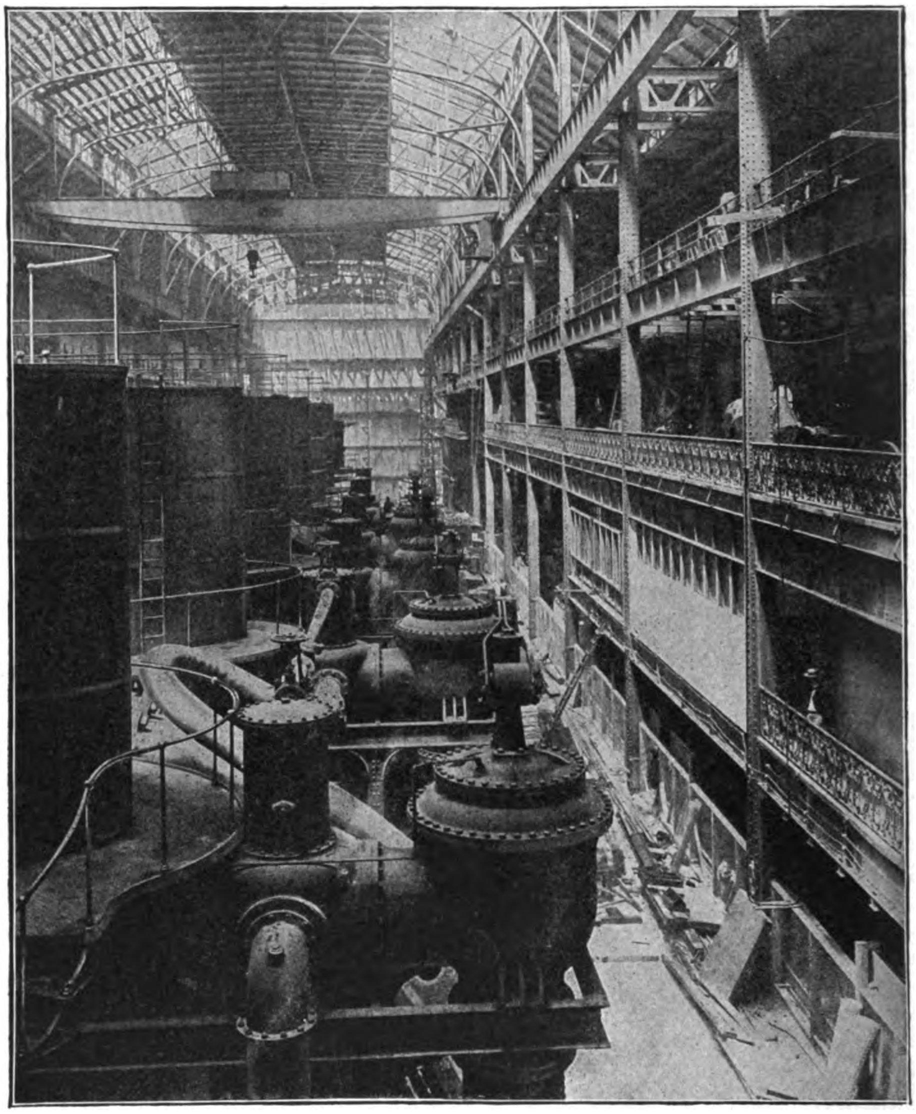

FIG. 9.—OPERATING ROOM IN POWER HOUSE, SHOWING CONDENSERS.

Condensing System.—The condensing system for each engine-generator unit will consist of two Alberger jet condensers with barometric column discharge, two hotwells of concrete and expanded metal into which the barometric columns discharge, one dry vacuum pump, and one cross-compound circulating-water pump. Each condenser is supported on specially designed steel work in front of the engine, and is connected directly to the exhaust outlet of the low-pressure cylinder by means of a single elbow on one side and to the relief valve of the atmospheric exhaust on the other. The condenser head or chamber is 50 inches in diameter and terminates at the bottom in a cone-shaped connection to the tail pipe, while the top is provided with a chamber in which the entrained air and vapor collect and to which is connected the air pipe to the dry vacuum pump. On the side 90 degrees from the steam pipe and the exhaust relief valve the circulating water enters, while directly opposite in the vapor chamber is the air pump connection. The water for use in the condensers will be taken from the North River through a tunnel located under Fifty-eighth Street into suction wells just outside the building. From these suction wells the water is delivered to the condensers by the circulating pumps; which are of the crank and fly-wheel double-acting Corliss type cross-compound, with cylinders of 10 and 20 inches in diameter and 30-in. stroke. The pumps are equipped with two externally packed double-acting plungers 20 inches in diameter, with 30-in. stroke. The normal speed is forty revolutions per minute, but the pumps are under the control of governors which may be set to allow the pump to run at any speed up to 50 revolutions per minute. These pumps have a normal capacity of about 7,000,000 gallons in twenty-four hours and are able to deliver 10,000,000 gallons in the same time if it is necessary. The water enters the pumps from the suction wells through cast-iron suction pipes 24 inches in diameter. These pipes pass under the boiler house basement through concrete-lined trenches, which are covered with cast-iron plates. The delivery pipes from the pumps are 18 inches in diameter, ending in two 14-in. pipes which go around the foundation to the condensers. The circulating pumps of each section are cross-connected in such a manner that either pump can supply either set of condensers in that section. After leaving the condensers, the water passes down through the tail pipe into the hotwells, through the discharge trenches in the basement floor into the discharge tunnel (also under Fifty-eighth Street), and thence back into the river.

The intake tunnel is of concrete. It is 10 feet wide in the clear and 8 ft. 6 ins. high.; the roof and bottom are arched to a radius of 10 feet, with 16-in. fillets in the corners. The side walls are 2 ft. 4 ins. thick and the floor is 3 feet, while the roof is 2 feet thick.

The suction wells are circular, 7 feet inside diameter, and are of concrete to the top of the intake tunnel, 13 ft. 6 ins. above the foundation; above this they are of brick and have a cover of brick arches turned between I-beams. These suction wells are connected with the tunnel by means of openings 7 feet wide and 5 feet high. The bottom of the intake tunnel and the wells is 19 feet below the city datum line or 10 feet below the lowest tide on record. The mouth of the intake tunnel at the river wall is protected by specially designed grids and screens.

The tunnel through which the water from the hotwells is discharged back into the river is located directly over the intake tunnel until within about 100 feet of the river wall, where it branches into two divisions and connects with two timber conduits built into the construction of the pier and carried out 100 feet from the face of the river wall where the mouth of the intake tunnel is located, thus obviating the possibility of the discharge water mixing with the intake water.

The generating units in this power house consist of nine engines and alternators, four turbine-alternators, and five exciter units. The main reciprocating engines are of the type used in the Manhattan Railway power house, which are familiar from having been so often described. However, it may be recalled that they are of the double cross-compound type, with the high-pressure cylinders horizontal and the low-pressure cylinders vertical. The dimensions of the cylinders are 42 ins. and 86 ins. in diameter by 60 ins. stroke, and the speed is 75 revolutions per minute. Both pistons of each engine are connected to one crank-pin. Steam enters the high-pressure cylinder at from 175 to 200 pounds pressure, through a 14-in. pipe, and from there passes into a receiver through a 16-in. pipe, from which it passes to the low-pressure cylinder. This receiver is not steam-jacketed. The normal rating of each engine is 8,000 horse-power, with a 50 per cent. over-load capacity. In one feature these engines will differ from those in the Manhattan power house; they are to have poppet-valves on all the high-pressure cylinders to provide for the use of superheated steam. The usual Corliss valve-gear is used on the low-pressure cylinders. The generators are of the Westinghouse revolving-field fly-wheel type, the field being mounted directly on the engine shaft. They have a capacity of 5000 kilowatts each and furnish 25-cycle three-phase alternating current at 11,000 volts. The machines have forty poles and revolve at 75 revolutions per minute.

In the turbine section provision has been made for four steam turbines, three of which have been erected. These turbines are of the Westinghouse-Parsons type and are direct-connected to 11,000-volt 1250-kw 60-cycle generators, which will supply the current for lighting the stations and subway.

In the same section the five exciting sets have been erected, two of which are steam driven and consist of 400-h.p. vertical cross-compound engines direct-connected to 250-kw. 250-volt direct-current generators. The engines are designed for a steam pressure of 175 pounds and will run at a speed of 150 revolutions per minute. The cylinders are 17 and 27 inches in diameter and the stroke is 24 inches. The other exciter units consist of three 250-kw. 250-volt direct-current generators, motor driven.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION.

The National Electrical Contractors' Association held its fourth annual convention in St. Louis, on September 14, 15 and 16, in the Century Building. All of the meetings with the exception of the morning session of September 16 were held behind closed doors.

At 10 a. m. on September 14 the meeting of the national board of directors was held. This adjourned for the opening meeting of the convention at 2 o'clock in the afternoon. In the absence of Hon. Rolla Wells, Mayor of St. Louis, who was to have given an address of welcome, Mr. E. C. Van Nort, president of the local organization, addressed the assemblage. He stated that the St. Louis organization recognized the fact that members of the convention were in the city first for business and secondly to visit the Exposition. He assured them that members of the St. Louis branch would do everything in their power to make their visit a pleasant as well as a profitable one. After complimenting the officers of the Association on the efficient manner in which affairs had been conducted, he closed by presenting to the convention Mr. E. McCleary, president of the national organization, who responded to the address of welcome.

A business session behind closed doors was held on September 15. The morning of September 16 was taken up by a meeting to which manufacturers and the Western Supply Dealers' Association had been invited. Questions of mutual interest to the three bodies present were freely discussed. Probably the most important discussion was on the subject of state licensing for electrical contractors. Messrs. Eidlitz, Gray, Galloway and Kneider presented the advantages of such a procedure and the question was carefully analyzed in its several aspects. It is a matter of interest to know that the State of Minnesota, as well as the cities of Washington, D. C., and Denver, Colo., have such a system.

Mr. G. W. Sanborn, Indianapolis, chairman of the Underwriters' Committee, was called upon and discussed developments bearing on the Underwriters' rulings.

Mr. W. S. Sisson, of the D. & W. Fuse Company, Providence, was asked to make clear several points as to fuse construction and to speak on the matter of the adoption of the new type knife blade fuse. In response to this invitation, Mr. Sisson said his company preferred to hold to the improved type "A" fuse, but that his company would furnish the new type at the request of the Underwriters.

Mr. W. W. Low, of Chicago, president of the Electrical Supply Dealers' Association, spoke as to the sympathy and interest which should exist between the supply dealers and contractors.

Mr. C. E. Flack, of the American Conduit Manufacturing Company, Pittsburg, was asked to explain the method of construction in its armored conduits.

C. E. Lee, of the Electric Gas Light Company, Boston, made a brief explanation as to the methods of his company in protecting electrical contractors in making sales. At the close of Mr. Lee's remarks his company was heartily commended by the association for its attitude and the individual members of the association were asked to favor this company in their patronage.

Mr. H. B. Coho, of the Keystone Electric Company, Erie, Pa., addressed the association on the advantages of contractors following more universally the practice of making their own installations of electrical machinery.

After the meeting the Electrical Contractors' Association had its last session, which was held in private. Boston was selected as the meeting place of the national convention to be held in 1905.

With the exception of W. I. Gray, former vice-president, who was unable to serve another term, all the old officers were elected for the coming year.

Quite an elaborate programme had been prepared by the Ladies' Auxiliary, of which Mrs. E. C. Van Nort is president, for the entertainment of the ladies accompanying members. On Wednesday morning at 10:30 the ladies met at the Jefferson Hotel for an automobile ride through the residential portion of the city and through the World's Fair grounds. Luncheon was served at the eastern pavilion on Art Hill. At 6 o'clock, the ladies were joined at the Missouri Building by the members of the Association. On Friday afternoon the ladies assembled at the General Electric headquarters in the Electricity Building for a boat ride on the lagoon. At 6 o'clock they again met at the General Electric booth where members of the Association were in waiting to escort them to a 7 o'clock dinner at Blanke's Café on the Pike. During the evening addresses were made by Mr. Charles Eidlitz, past president and organizer of the Association, and by Mr. Lowe, president of the Western Supply Dealers' Association. The event of the occasion, however, was the presentation of a loving cup by the Association, to Mr. Eidlitz. Thus cup, appropriately inscribed, was given as a token of appreciation for past and present services.

NORTHWESTERN ELECTRICAL ASSOCIATION.

The Northwestern Electrical Association held a short business session at the Forest Park University Hotel, St. Louis, on September 12. After the business had been disposed of, the Association adjourned to attend the meetings of the International Electrical Congress, in many of the papers of which the members were interested; several of the members were also members of the Congress.

THE FIFTH INTERNATIONAL ELECTRICAL CONGRESS.

ST. LOUIS, SEPTEMBER 12 TO 17.

The fifth International Electrical Congress, which met in the Coliseum Music Hall, St. Louis, opened in general session on Monday morning, September 12, with President Elihu Thomson in the chair. President Francis, of the Louisiana Purchase Exposition, delivered an address of welcome, and after appropriate addresses by the presidents of the British Institution of Electrical Engineers, the Italian Electrotechnical Association, and the American Institute of Electrical Engineers, the Congress divided into sections for the reading and discussion of papers. Section "A" was devoted to General Theory; Section "B" to General Applications; Section "C" to Electrochemistry; Section "D" to Electric Power Transmission; Section "E" to Electric Light and Distribution; Section "F" to Electric Transportation; Section "G" to Electric Communications; Section "H" to Electrotherapeutics. As the papers read in Section E related more closely to central station practice than those of any other sections, the proceedings of that section are given rather more fully than the others in the following report.

SECTION A.

The sessions of Section A were opened on Monday, September 12, by the reading of a paper on "The Mechanical Equivalent of Heat Measured by Electrical Means," by Dr. H. J. Barnes. The paper gives a critical comparison of this constant as determined by mechanical and electrical methods, and presents the results obtained by the author by the use of the latter method. The next paper on the programme, "Spectra Gases at High Temperatures," by Prof. John Trowbridge, contains statements of various phenomena observed on discharging a condenser of high e.m.f. through Geissler tubes. Next followed a paper entitled "The Alternating-Current Theory of Transmission Speed Over Submarine Telegraph Cables," by Dr. A. E. Kennelly, who attacks the problem mathematically. The conclusion reached is that the inductance of the receiver should equal the condensance of the sending circuit, and that these values should also equal the ohmic resistance of the circuit. The results depend upon the assumption that the signals consist of a succession of dots sent at regular intervals, but the author expresses the opinion that the effect of dashes would probably be of secondary importance. The concluding paper of Monday's session was that by Prof. Townsend, entitled "The Theory of Ionization by Collision," which was read by title.

The first paper of Tuesday was "Systems of Electric Units," by Professor M. Ascoli. The paper advocates the adoption of a rational system of units as proposed by Professor Giorgi, of Rome. The next paper, "The Absolute Value of the Electromotive-Force of the Clark Cell," by Professors H. S. Carhart and G. W. Patterson, Jr., was in two parts. The first, by Professor Carhart, contains a description of the electrodynamometer used by the authors in their work; the second, by Professor Patterson, contains the mathematical derivation of the expression of the torque of the dynamometer.

In a paper entitled "The So-Called International Electrical Units," Dr. F. A. Wolff discussed the differences in the units as legalized by the principal European and American nations, and the apparent multiplicity of the same units in several individual governments. The author recommends some action that will bring about closer unification.

The reading of these three papers was followed by a joint discussion participated in by members of the American Institute of Electrical Engineers and the British Institution of Electrical Engineers. The speakers were Dr. R. T. Glazebrook, Professor A. G. Webster, Professor H. S. Carhart, Mr. H. E. Harrison, Dr. A. E. Kennelly, Professor John Perry, Dr. F. A. Wolff, Mr. C. H. Sharp, Professor Patterson and Mr. Duddell.

The discussion developed a decided tendency toward conservative handling of the question of changing existing units and standards. Broadly speaking, the discussions were confined to two principal topics: First, the matter of fixing upon a concrete standard of e.m.f. as exemplified by the Clark and Weston normal cells, or of displacing both in favor of the silver voltameter standard; and secondly, the question of rationalizing units in general.

The American speakers were in favor of retaining only the standard cell as the basis of comparison, because of the ease with which it can be handled, and because of recently discovered methods for obtaining pure ingredients; the foreign delegates, on the other hand, seemed disposed to hold to the silver voltameter. With regard to the general system of units, it seemed to be the consensus of opinion that it is too late for any radical change, and that it is best to "let well enough alone."

It was generally agreed that the time is not ripe for recommending legal changes in the accepted value of the e.m.f. of the Clark cell; nor for any action tending toward the replacement of this cell by the Weston cadmium (normal) cell.

At the session of Thursday, September 15, Professor S. Arrhenius presided. The first paper presented was on "The Electric Arc," by Professor C. D. Child. The paper presents an explanation of the phenomena of the arc based on the electron theory. The paper was discussed by Dr. H. T. Barnes and Mr. P. H. Thomas.

"The Absolute Measurement of Inductance," by Dr. E. B. Rosa and Mr. F. W. Grover, was the next paper. These measurements, made at the National Bureau of Standards, were undertaken to determine whether inductance could be measured with sufficient accuracy to establish a basis for determining the ohm in absolute measure. The paper was discussed by Mr. Dryesdale.

Professor E. Rutherford then read a paper entitled "The Corpuscular Theory," by Professor J. J. Thomson. The paper describes experiments made to determine whether there is the same relation between mass and weight in radium as exists in the case of ordinary substances. It has been thought that the peculiar internal conditions of radium might cause a difference in this ratio.

The final paper of the session, "Coherer Action," by Dr. K. E. Guthe, was read in abstract by Mr. A. S. McAllister.

The first paper of the final session on Friday, September 16, was entitled "The State of Our Knowledge Regarding the Earth's Magnetism and Most Recent Remarkable Magnetic Storms," the author being Dr. L. A. Bauer.

In the discussion which followed, Messrs. Glazebrook, Steinmetz and Bauer participated. The discussion turned mainly to the question of protecting magnetic observatories from disturbances by leakage currents from power circuits.

Dr. Svante Arrhenius then presented his paper "On the Relation Between the Sun's Rays and Electromagnetic Disturbances on the Earth."

The discussion was participated in by Messrs. Rutherford, Steinmetz and Arrhenius. The discussion was followed by a paper on "Radioactive Change," by Professor E. Rutherford, which had the form of a report of further work on transition stages of radium.

Professor A. G. Webster followed with a paper entitled "Report on Recent Developments in Electrical Theory." This is a long mathematical paper, not capable of being abstracted, and dealing with Lorentz's electron theory.

SECTION B.

The sessions of Section B were opened on Monday by the presentation of a paper by W. M. Mordey, on "Eddies and Hysteresis in Iron," which was read by Professor Samuel Sheldon in the absence of the author. The author has found, experimentally, that even with the sheet steel of small thicknesses the eddy current losses are quite large in comparison with the total iron loss, and are by no means negligible, as is frequently assumed. The eddy losses do not vary as the square of the thickness of the sheets nor as the square of the frequency. In fact, the eddy losses are found to vary according to the 1.6 power of the frequency, as is true of hysteresis and as the first power of the thickness of sheets. This is due to the inductive effect of the electric circuit through which the eddy currents must flow. Thus, in the increase of either the frequency or the thickness of the sheets, the skin effect becomes more pronounced, the net result being that the eddy current loss follows a law more or less the same as applies to hysteresis, depending on the relative values of the hysteretic constant of the iron and the electrical conductivity of the material. It is suggested that the proper method for testing for iron loss is with a wattmeter, using sheets of commercial size.

In his paper on "Magnetic Viscosity," which was read by Mr. W. I. Slichter, Mr. M. R. Jouraust described experiments to show the presence of an appreciable time lag in the building up of magnetism after the application of the magnetomotive force. This effect is found to be more prominent if the magnetism is taken from a certain small positive value to a similar negative one than when decreased, through the same range, from a large positive to a small positive value. It is attributable to the sluggish movement of the molecular magnets at the period of instability. It is found also that there is generated by the change in flux a local current which tends to retard the change. With large masses of steel the viscosity effect is quite noticeable, but with commercial laminations it is inappreciable. The effect has been noted with other magnetic materials, as ferro manganese, and especially in cast metals.

In discussing this paper, Professor Steinmetz stated that it had been frequently assumed that the loss per cycle due to hysteresis depended not only on the maximum density, but also on the rapidity of reversal. Investigations have shown that for commercial frequencies hysteresis is represented by so much energy per cycle and is practically independent of the frequency. A fact which has a bearing on engineering work is that the flux produced by a certain magnetomotive force is less for alternating than for direct current. This fact is of importance with alternating current railway motors and various types of meters. Professor H. J. Ryan called attention to the necessity of observing the shape of the curves in alternating current work, and stated that results obtained with wattmeter tests of losses and Duddell oscillograph records of shape of waves would furnish valuable information for investigators of these complex phenomena. Mr. Ford reported the results of tests made at Columbia University to determine the effect of eddy currents upon the hysteresis loop. Experiments had shown that the sharp points of the loop were not rounded, due to any increase of frequency, but that any rounding observed could be attributed to eddy currents in the iron. In commenting on Mr. Mordey's paper, Dr. Sharp said that true test results could best be obtained with iron sheets built up to convenient commercial size, a wattmeter being used for finding the iron loss. For minimum loss there should be used iron having high specific resistance and low hysteretic constant. Professor C. A. Adams drew attention to the fact that the shape of the curve showing the relation of iron loss and frequency would depend upon the constants assumed for the hysteresis and for the eddy loss. He stated that the results of tests which had been made upon commercial iron sheets when subjected to various densities at different frequencies were quite consistent for frequencies between 25 and 300 cycles per second, when the assumption was made that the eddy loss varied as the square and the hysteresis as the 1.6 power of the density, proper values for the constants being thus determined. With reference to the determination of the hysteresis loop of transformers, Mr. Duddell outlined a most interesting method involving the use of an oscillograph for showing the loop directly.

Dr. C. H. Sharp read his paper on "The Equipment of a Commercial Testing Laboratory," which dealt with laboratories intended not for purposes of instruction, but as commercial enterprises. Thus the prime requisites are dispatch, accuracy and economy. This paper was not discussed.

Dr. C. P. Steinmetz abstracted the paper of Mr. Albert Nowon on "Electrolytic Rectifiers—An Experimental Research." It is impossible to obtain a unidirectional electromotive force by magnetic induction with stationary apparatus, due to the fact that a changing flux which produces an e.m.f. of one sign when increasing in value, must give an e.m.f. of reversed sign when its value is on the decrease. Therefore, electromagnetic apparatus for producing unidirectional e.m.f. must be of the open magnet circuit type, and one part must slide or rotate with reference to the other, and in general a commutating device must be employed. With the electrolytic rectifier or the so-called electrolytic valves, the current is allowed to flow more freely in one direction than in the other, the effective resistance being small for current in one direction and large for current in the other direction. When the valve effect is perfect the effective resistance is low for current of one sign and is infinite for current of the other. A certain hysteresis effect is produced at the surface of the electrode, the process occurring at this place not being entirely reversible and resulting in an energy loss. This loss is constant and forms the no-load loss of the rectifier. The efficiency is determined by the value of this loss and an additional loss which varies with the square of the local current, due to the resistance of the circuit through which the current must pass. A single rectifier gives an interrupted pulsating current. By the combination of several rectifiers whose currents are superposed or which are used with energy storing devices, a truly unidirectional and constant e.m.f. or current may be obtained. The proper arrangements to be used are described by the author.

The paper of Mr. B. A. Behrend on **The Testing of Alternating-Current Generators** was read by Mr. W. I. Slichter. The paper describes an improved method for testing alternating-current generators and synchronous motors under full-load conditions, without actually having to place the machines under full load. Instead of having to divide the armature into two sections, as suggested first by Mr. Mordey, Mr. Behrend splits the fields into two sections and connects these sections in such a manner that the e.m.fs. induced in the armature are in opposition. Test curves given in the paper show that the method produces results closely equivalent to loading the machines.

Professor H. J. Ryan, on account of the great convenience and efficiency of the method proposed by Mr. Behrend, suggested that a systematic comparison of results obtained by actually loading various machines and by calculations based upon the method proposed would be most interesting and instructive as furnishing constants of design of different types of machines. Mr. W. L. Waters expressed his doubt as to the accuracy of the results to be obtained from machines of widely different types by the Behrend method. He has found that very good results may be gotten from passing direct current through the divided armature circuits and that the vibration of the machine, while of appreciable magnitude, does no harm. On account of the field coil circuit being cut by the magnetism, due to the direct current in the armature, a short-circuit current is produced in the field coils, and the effect of this action must be taken into account. The method of loading the machine with inductive coils for a short time serves to heat up the machine, while the power-factor being low the energy consumed is small and the results are quite satisfactory. Mr. D. B. Rushmore stated that an asymmetrical connection of the armature conductors so as to give unbalanced e.m.f. in the locally closed armature circuit had been found to give good results. In fact, commercial accuracy was obtained by determining the regulation from the short-circuit and open-circuit tests, using either the magnetomotive force or the electromotive force methods. Mr. Steinmetz laid emphasis on the fact that the best method of testing an alternator for efficiency, temperature rises and regulations is by actually loading the machine. Such procedure is practically impossible with large generators and methods of calculation must be used. Experience has shown that the calculated results were even more accurate than the observed results due to the difficulties in controlling the condition of a test under load. An excellent plan is to operate the machine on short circuit for a certain time and on open circuit with excess excitation for a certain time, in order to get the full temperature rise. The length of time for each condition of test depends upon the type of machine, and experience shows the values to be assigned to each. Professor C. A. Adams stated that whether the electromotive force method or the magnetomotive force method should be used depended upon the type of machine being tested. The electromotive force or reactance method had been found good for all types of machines.

On Tuesday, September 13, Sections B and F met in joint session. The first paper of the day, by B. J. Arnold, on "Some Early Work in Polyphase and Single-Phase Electric Traction," referred to the history of the work done by the author since 1896 in the solution of traction problems.

Professor C. P. Steinmetz then presented his paper on "Alternating Current Motors," which is an elaborate general mathematical treatment of the subject. The paper on "Single-Phase Motors," by Max Deri, was read by Mr. Slichter, this also treating the subject from the mathematical standpoint. Marius Latour presented his paper on "Single-Phase Motors," which discussed in particular the compensated repulsion motor upon which he has been working for several years. In regard to the commutation, he showed that the e.m.f. in the coil short circuited by the brush has two components, one due to transformer action and the other due to speed. The former is practically constant, while the latter varies with the speed. At synchronism the two components are equal in value and, being opposite in phase, the resultant is zero, so that the commutation at this speed is perfect. The paper disclosed a method for improving the commutation at all speeds by use of coils connected electrically in shunt across the power circuit and placed mechanically so as to generate a proper counter e.m.f. in the coil under the brush, thus eliminating the sparking troubles. Dr. O. S. Bradstad's paper on "Theory and Operation of Repulsion Motor" was abstracted by Professor C. P. Steinmetz. The paper is mathematical in character, a general equation for the repulsion motor being derived, and the conditions which must be fulfilled to give maximum power, maximum torque or maximum power-factor are discussed. A method of determining the characteristics of the machine from open circuit and short circuit tests is given. This method corresponds closely to the one which is applicable to induction motors and transformers and to the one which is used in the synchronous motors and generators. The author uses the method of complex quantities and gives diagrams to represent his equations. Professor Steinmetz abstracted briefly the paper by Ernst Danielson on "The Theory of the Compensated Repulsion Motor." The author determines the distribution of the magnetomotive force and the flux, and in this way derives a general equation for the machine. He treats of the compensation and of the conditions for obtaining good commutation and reports the results of tests on certain motors. The paper is largely mathematical and cannot be readily abstracted. Mr. P. M. Lincoln presented a paper on

Transmission and Distribution Problems Peculiar to Single-Phase Railways.

An apparent handicap for the single-phase in comparison with the three-phase transmission system is the fact that the copper required is in the ratio of 4 to 3. This ratio holds true on the basis of equal potential between wires, but if equal normal potential to ground be considered the basis then the single-phase and the three-phase are on an equality. A polyphase generator is cheaper by 30 per cent than a single-phase machine of the same capacity, hence it is advantageous to use polyphase generators for supply, dividing the load as equally among the phases as possible. A disadvantage is found in thus operating from a polyphase circuit, since if one of the three wires be taken away, the sum of the static potentials no longer remains at zero, and static induction will take place on neighboring (telephone) circuits without the possibility of correction by any method of transposition. After discussing the application of Kelvin's law for the determination of maximum commercial economy of conducting material and the relation of the voltage drop to the spacing of transformer stations, the author concludes that there is no golden rule for the determination of the spacing and capacity of transformer stations or of the size of the conductor. It is a matter of compromise between various elements, some of which point in one direction and some in the other, and is a matter which must be determined by engineering judgment rather than by any inflexible law.

The paper by Dr. F. Niethammer on "Alternating vs. Direct-Current Traction" was presented to the members in printed form and was not read, owing to its great length.

In discussing the relative advantages of three-phase and single-phase motors as to the torque exerted by each, Mr. E. K. Scott compared the machines to three-crank and single-crank engines. The polyphase and the direct-current motors give constant torque, but the torque of the single-phase series motor is pulsating. In order that the wheels of an electric locomotive should not slip when equipped with alternating current series motors, it must be sufficiently heavy to adhere to the track for maximum torque, and, therefore, the locomotive must be larger than when direct-current motors are used. In a three-phase, delta-connected system, if one transformer is damaged the other two will carry the load, but in a single-phase system the loss of one transformer shuts down the circuits. Mr. B. G. Lamme explained why the air-gap of a single-phase series motor could be made so much larger than that of induction motors without detrimental effect upon the power factor at operating speeds. A fact which seems little appreciated is that with the single-phase motor both wattless and energy current produce torque, while with the induction motor only the power component of the current represents torque. Thus a low power factor at starting does not indicate poor torque. On the contrary, the lower the power factor the better the motor, since all power current indicates internal losses. The Westinghouse Company uses the directly compensated motor with exact compensation. The method of determining the degree of compensation is to short circuit the compensating coil while current flows in the armature. If the compensation is excessive current will flow in the local circuit in one direction; if too weak, the current will flow in the other.

In discussing the relative advantages of single-phase and polyphase induction motors, Professor C. P. Steinmetz stated that the operating range of the single-phase motor is much more limited than that of the polyphase. The polyphase motor could be used for railway work, but the single-phase is unsuited except by some such scheme as that used by Arnold. The commutator motors are not limited as to speed range, the torque varying inversely with change of speed as with the direct-current machine, and closely as the square of the current. A polyphase motor gives a torque varying as the first power of the current; the single-phase commutator motor shows the best torque efficiency. In reply to the criticism of Mr. E. K. Scott, Professor Steinmetz stated that single-crank tandem compound engines were found to be as good as two-crank engines, the pulsating torque not being objectionable. He directed attention to the fact that there is no dead-center with a series motor, the torque pulsating at a rate depending upon the frequency and quite independent of the speed. As to the type of generator to select, a polyphase generator is somewhat smaller than a single-phase machine and polyphase motors are preferable for stationary duties. It seems best to generate polyphase and distribute single-phase. The ideal system is single-phase for both generation and distribution. Mr. A. H. Armstrong stated that railways being installed must conform as nearly as possible to existing systems.

Mr. H. W. Leonard stated that he had early been an advocate of the single-phase system for railway work, and described the electric locomotive known by his name.

Commenting on the Bragstadt paper, Mr. W. L. Waters remarked that, while the best method of representing the performance of motors is by means of graphical diagrams, the computation connected with single-phase motors required analytical equations, and it is best to use both the graphical and analytical methods. In regard to the transmission circuits, it is evident that, compared upon the proper basis of e.m.f. to neutral point, the single-phase system is equally as good as the three-phase.

Mr. P. M. Lincoln stated that the Westinghouse Company had at first advocated a low trolley voltage which would permit of the use of insulation when available for street railway work. Thus, standard insulators were adequate for 1,000 volts, but were too weak for 2200 and 3300 volts. At present, however, trolley insulators conforming to standard practice are available which will withstand the latter pressures.

At the opening of Section B, on Thursday, Professor S. P. Thompson not being present, Professor C. P. Steinmetz abstracted his paper on "Plunger Electromagnets," which dealt with the problem of the proper design of plunger magnets so as to give a force which varied but little throughout a large range of stroke. The author shows how to calculate the reluctance of the magnetic path and to determine the m.m.f. necessary to produce a given flux. The problem, which is quite easy for closed magnetic circuits, becomes quite complex when open circuits are used, due to the so-called demagnetizing effect of the end poles. He explains the method of ascertaining the surfaces to be given to the coil which must dissipate a certain amount of heat when the magnet is used either for constant service, temporary service or intermittent service. The method of magnetic images is employed. It is shown that the equivalent effect of a long magnet may be obtained by means of plates at the pole ends.

The paper by Professor E. B. Rosa, Dr. M. G. Lloyd and Mr. C. E. Reid, on "Wave Shape and Meter Indications," represented the results of tests made at the Bureau of Standards to determine the effect of variation of wave form of e.m.f. upon the indications of the meter.

Professor H. J. Ryan presented his paper on

The Design of Insulators.

In the design of insulators to withstand high electric pressures the following methods and data are useful: (1) A convenient system of fixing quantitatively the flux electric force produced by an e.m.f. in a dielectric, causing the electric strain therein. (2) The permeability of an insulation to flux the electric force produced by an e.m.f. (3) The density of flux of electric force which the ultimate electric strength of an insulation is called upon to withstand and at which rupture occurs. (4) Expedients that localize the application of the electric strain within those portions of an insulating system that are most powerful and capable of standing the total strain. (5) Experimental methods for testing the dielectric materials to ascertain the proper construction so as to secure their breaking strains, that is, the densities of electric force flux at which their ultimate rupturing strength is developed, and for testing completed insulations or insulators to determine the manner in which they will satisfy the requirements and to determine the design factors. (6) Factors of safety as determined by trained judgment. After discussing each of these topics in detail the author calls attention to the fact that a far less proportionate use of mathematics can be made in determining necessary dimensions in the design of insulation than is the case correspondingly for either of the other two components of electrical machinery and apparatus, viz., the circuits accommodating electric current and magnetism.

In commenting on the paper Mr. D. B. Rushmore expressed his appreciation of the valuable work done by Professor Ryan in placing the insulation of electrical machinery on a scientific basis in so simple a manner. He referred to the fact that while formerly cotton covering was depended upon for insulation in transformers, the tendency to-day is to use some separator for the conductors and depend entirely upon oil for insulation. In reply to Mr. Rushmore's question as to the existence of dielectric hysteresis, Professor Ryan related his experiences with the heating of dielectrics, which seemed to show that, while such hysteresis might be present, the heating could in every case be attributed to local weakening of the dielectric under excess stress which rendered it conducting, after which it heated rapidly and finally gave way.

Electric Motors in Machine Shop Service was the subject of a paper presented by C. Day. The author considers the subject from the standpoint of the engineer. The motor-driven tool of the future should be not a combination but a unit suited for certain specific ends. When a machine is purchased, the customer should have the assurance that the drive has been given the same care in design and construction as any other part of the machine. Apparatus should be primarily designed to be satisfactory in the hands of average workers. When equipping machines of old design with motor drive each one should be considered separately with regard to the special line of work it handles. Systems now on the market for obtaining adjustable speed are field weakening alone, double commutator motor combined with field weakening, Edison three-wire, unbalanced three-wire and four-wire multiple voltage systems, each combined with field weakening. The conditions which must be met by the machine builders necessitating the selection of a type that does not require for its operation special auxiliary apparatus are pointed out. While motors operating on two wires and giving a range as high as 4 to 1 by means of field weakening do not at present give as good all around results as those operating on the multiple-voltage and three-wire systems, their adoption by manufacturers is certainly justified in many instances. After the reading of this paper, Sections B and E combined to discuss Col. R. E. B. Crompton's paper on "Standardization of Dynamo Electric Machinery," which had been read the day previous.

Mr. J. W. Lieb, Jr. called attention to the frequency of 50 cycles which the English committee had suggested to fill the duty performed by the American 60 cycles and thought that the two countries should combine on a common value. Professor C. P. Steinmetz remarked that the difficulty in specifying standard frequencies is due to the fact that there are three supreme courts for discussion, the electrical engineer, the customer and the builder. Fifty cycles had been tried in this country in '92-'93, but practice crystallized toward 60 cycles, which value has been the accepted one here for the past six years. It does not seem possible that America could adopt 50 cycles, though perhaps a common frequency for both England and America could be found in 60 cycles. Colonel Crompton related the reasons for the suggestion of 25 and 50 cycles as standard frequencies. Fifty cycles can better be used for rotary converters than 60 cycles, while a lower frequency, such as 40, while better for converters, is not suited for general illumination. The ratio of 50 to 25, the best frequency for general power purposes, is just 2 to 1, and furthermore, Germany has adopted 50 cycles.

Mr. C. F. Scott stated that from personal observations he had found a great need for standardization in England, where the number of frequencies in use is simply appalling. In America, the conditions differ from those in England, since a few large companies control the manufacture of machinery and the engineers have early recognized the advantage of standardization. A danger which may follow standardization is a checking of progress of development. The suggestions should be given as a guide, not as a law. Dr. R. T. Glazebrook wished to correct the impression that in England the suggestions made would become law, since in reality there could be no rigid rules laid down and no supreme council to see that they were followed. The suggestions would be availed of in just so far as they proved proper for the conditions existing.

Professor F. B. Crocker related his early experience in standardizing apparatus. President R. K. Gray, of the (British) Institution of Electrical Engineers, agreed with Mr. Scott as to the suggestion for guidance and not law in connection with the standardization, which should be made in conformity to the wishes of all concerned and not involve the necessity of compulsion in its adoption.

Professor Moise Ascoli expressed his appreciation of the work being done, and stated that though no standardization had as yet been attempted in Italy, the engineers of that country would profit by the suggestions now being made when they undertook a similar task. Col. Crompton, in closing the discussion, thanked the Congress for the attention paid the subject and expressed his pleasure at the general accord of opinion of the American and English engineers as to standardization, the only difference noticed being in regard to the frequency. He stated that the Board of Trade, which had relatively considerable power in England, had in the past issued rules which were valuable for the protection of lives from electrical dangers. No compulsion had been used and no obstruction to progress had been offered. Recently the upper limit to low-tension voltage had been raised to conform to improved conditions of insulation.

At the opening of the final meeting on Friday, the paper presented by Mr. F. J. Eichberg on "Single-Phase Electric Railways" was presented in abstract by Professor C. P. Steinmetz. The paper described the type of single-phase commutator motor known as the Winter-Eichberg machine, which gives the series motor characteristics. The motor possesses two sets of brushes, mutually at right angles to each other. One set receives the energy current by transformer action and the other exciting current by direct series connection in the circuit. It was shown by Professor Steinmetz that the general type of commutator motor contains four circuits, two on the stator and two on the rotor; of these, only two are necessary for operation, one for energy and the other for excitation current. With the type of motor described three circuits are used, two of which are on the motor. The motor is quite similar in operation to a repulsion motor. Mr. W. I. Slichter abstracted the paper by M. Andre Blondel on "Calculations and Tests of Alternators," whch treated of the various methods of determining the performance of an alternator either by calculation or by test. Where two similar alternators are to be tested a convenient method is to connect them together mechanically and shift the relative phase of the two so as to cause a current to circulate locally through the armatures. A third machine which drives the set supplies the losses of the machine, while the motor machine of the set feeds back energy to the generator through the coupling shaft. He mentioned also the method of dividing the pole windings of a single machine into two groups and varying the current of the groups. This gives a motor-generator effect to the armature which is equivalent to loading the machine, where a large number of poles is used, but leads to error with machines having but a few poles. Mr. Slichter abstracted also the second paper by M. Andre Blondel on a somewhat similar subject, "Reaction in Alternators." The method followed by the author involves the determination of the magnetomotive force of the armature ampere turns and dividing the leakage flux due thereto into two components, the demagnetizing and the distorting. Account is taken of the effect of saturation of the armature and field cores. For single-phase machines the alternating magnetomotive force is resolved into two components, each of half value, revolving uniformly in opposite directions on the armature core, one, therefore, being stationary in space and the other traveling at double speed. Thus the reaction is pulsating in each machine. The author treats of the effect of the variation of the number of slots for single-phase and polyphase machines and shows methods for reducing the distortion. Mr. V. Karapetoff called attention to the fact that an exact treatment of the regulation of alternators must take into account the armature resistance, armature reactance, demagnetizing and cross magnetizing effects of the armature current. The reactance of the armature windings consists of the self-inductance of the section in the slots and of the section in air and the mutual inductance of the coils. It is not possible to combine all of these in one effect.

Mr. W. I. Slichter abstracted the paper by M. Paul Boucherot on "Kinetic Variation of E.M.F. in Dynamo Electric Generators and Its Influence on Their Operation in Parallel," which dealt with both direct and alternating-current generators, the dynamic action of a pendulum being the basis for the treatment with alternators. This paper was not discussed.

Professor C. A. Adams presented his paper on "Leakage Reactance of Induction Motors," which was a report on an experimental investigation of the effect on the leakage reactance of shifting the relative positions of the rotor and stator cores. Mr. D. B. Rushmore stated that the facts brought out were applicable to all classes of machinery. It is only in recent years that the designers of direct-current machinery have been considering the effect of the self-inductance of the armature coils. While the results sought are different in the several cases, the facts involved are the same in each. In reply to a question by Mr. Karapetoff, as to the effect upon the current taken by the induction motor on shifting the rotor and as to methods of separating the primary from the secondary leakage reactance, Professor Adams stated that the variation of current with a cage-wound rotor would be very slight indeed, due to the prime relation between the primary and secondary number of slots, but that with certain coil-wound secondaries the variation was as much as 30 per cent. As to the calculations of the reactances, they had been found to check within 5 per cent of the test values.

Mr. D. B. Rushmore presented his paper on "The Regulation of Alternators," which gives by description, inference and reference a summary of work done and of the methods commonly used for determining regulation and the results of very careful tests on widely different types of machines. The paper forms a contribution of real value concerning actual operation under many different conditions. The results of the tests are given in 27 curve sheets, which are accompanied by complete design data in order that the many possible valuable deductions may be made therefrom. The paper is especially valuable on account of the test data, in obtaining which the greatest care was taken with methods and instruments and on account of the fact that only those observations which could be repeated have been recorded. Mr. C. V. Dryesdale described a method of determining the regulation by use of the short circuit and open circuit characteristics. In this method there is plotted a third curve which represents the square of the magnetic reluctance of the machine, found as the ratio of field current to armature e.m.f. at full speed. By locating certain points on this curve by use of the short circuit characteristic at a given load current, the terminal e.m.f. of the generator is found on the excitation characteristic. The method takes into account the change in reluctance of the magnetic path and is, therefore, preferable to a method which neglects such change.

Recent Development in Compound Alternators with Alternating Current Self-Excitation.

This paper by A. Heyland was read in abstract by Mr. A. S. McAllister.

The main point of the system devised by the author is that single-phase or polyphase alternating current generated by the machine is led directly to the field windings for excitation and for compounding by means of a peculiar commutator. By the interposition and suitable inter-connection of transformers, or by certain circuit arrangements in a single transformer, the exciting current of the machine is taken off in shunt to the main winding and the compounding current in series, and so conducted to the commutator that the exciting current entering the field winding remains approximately constant for all loads, while the compounding current increases and decreases with the wattless component of the main current. The armature reaction can be annulled and the drop in voltage compensated for or the machine may be over compounded. In the latest constructions the field winding is divided into groups which are connected to the commutator in parallel to one another. By placing cross connections at the end of the conductors, the current is not interrupted, as was the case in the earlier arrangement, which has been abandoned for practical and constructive reasons. In a recent compounding connection, the polyphase exciting current is generated in three auxiliary coils which are located on the stator. In the same slot in which the auxiliary winding lies, there is placed a part of the main winding, the respective coils being, however, connected in opposite directions to the remaining part of the main winding. With a suitable choice of the number of turns of the compounding coils of the main winding, there can be obtained in this manner a complete compounding without a compounding transformer.

Mr. V. Karapetoff remarked that Mr. Heyland had devised numerous new types of machines in recent years, all of which involved the use of a special commutator. He explained that the most valuable feature of recent developments resided in the means for increasing the excitation of the generator directly with the wattless component of the armature current, while the power component had no effect upon the excitation. He pointed to the fact that periodically new and improved schemes were proposed by Mr. Heyland, a recent one involving the use of a separate exciter for the main field current while retaining the special commutator for counteracting the effect of the wattless component of the load current. A recent scheme consisted in causing the wattless component of the load current of generator to increase the field strength of a separate exciting generator. Professor Adams stated that the self-exciting features introduced by Mr. Heyland might prove advantageous for small plants, but they necessitate undue complications for large plants and central stations, where the use of separate generators for excitation is preferable. Mr. C. V. Dryesdale remarked that the Heyland generators operated very satisfactorily under test, and he thought that the auxiliary excitation of the exciting generator suggested many inviting possibilities. Mr. Rushmore said that schemes for compounding which are carried out on the generator itself are in general expensive and complicated. Methods are now in satisfactory use for performing this work external to the armature circuits of the generator and these seem to be preferable.

The paper by H. M. Hobart on "A

Method of Designing Induction Motors" was given by Professor H. J. Ryan.

Mr. D. B. Rushmore remarked that the author, being a designer of machines, was most liberal with his information, being a frequent contributor to the technical press. He felt that the electrical engineers owed a debt of gratitude to Mr. Hobart for the paper at hand, which so admirably presented the requirements of a good design for induction motors based upon actual experience with the machines. The papers now being read before conventions of engineers represent, he said, a change of attitude of the members of the profession. Much good is being accomplished through the free interchange of ideas which were previously held as trade secrets. Engineers have ceased to withhold information, and advantages have thereby been gained on all sides.

SECTION C.

Immediately after the inaugural general meeting of the Congress, Section C was organized with the following officers: Prof. Henry S. Carhart, chairman, and Mr. Carl Hering, secretary. The only paper presented at Monday's session was that of Prof. Theodore William Richards (Harvard University) on the relation of the hypothesis of compressible atoms of electrochemistry. In the absence of the author it was read by Dr. G. W. Patterson, and discussed very briefly by Prof. Carhart and Prof. Patterson with respect to the application of Richards' hypothesis to the Gibbs-Helmholtz equation.

In the absence of the president and secretary of the section during Tuesday's session, Dr. W. D. Bancroft acted as chairman and Mr. S. S. Sadtler as secretary. The first paper was presented by Mr. J. Sigfrid Edstrom on "Electric Extraction of Nitrogen From the Air." The paper dealt with the methods of Prof. C. Birkeland and Mr. S. Eyde, of Christiania.

A paper was then presented by Dr. Wilder D. Bancroft (Cornell University) on the "Chemistry of Electroplating." This discussion was opened by Dr. E. F. Kern, who read a long communication by Mr. A. G. Betts, criticising several of Dr. Bancroft's generalizations. Dr. Louis Kahlenberg emphasized that the chemical make-up of the solution is the vital factor. Prof. C. F. Burgess said whether one calls a deposit good or bad depends much upon the standpoint whether one is a refiner or an electroplater. In his reply, Dr. Bancroft said that the object of his paper was to give some distinct generalizations which can be tested by experiment and which can be proven to be either right or wrong.

Prof. F. Haber's and Dr. L. Bruner's paper on "The Carbon Cell" was then read, in absence of the authors, by Prof. C. F. Burgess. The discussion was opened by the reading of a communication by Mr. C. J. Reed, who thought that the authors had not given sufficient proof for their theory that the Jacques cell is essentially an oxygen-hydrogen gas cell. He believes that Ostwald's explanation of the chemical action in the cell is the correct one. Some brief remarks were made by Prof. Bancroft and Prof. Kahlenberg.

The next paper was presented by Dr. Louis Kahlenberg (University of Wisconsin) on "The Electrochemical Series of the Metals." In the discussion of the paper Prof. W. D. Bancroft and Dr. H. E. Patten took part.

Mr. A. G. Betts' and Dr. E. F. Kern's paper on the "Lead Voltameter" was then read by Dr. Kern. There was no discussion.

The last paper of the session was Mr. James Swinburne's (London) paper on "Chlorine in Metallurgy." In the brief discussion which followed Dr. W. D. Bancroft referred to the trouble which electrolytic alkali manufacturers have with the chlorine generated since there is an overproduction of bleaching powder. Mr. S. S. Sadtler said that Mr. Swinburne's scheme of treating complex sulphide ores is of great simplicity on paper, but on a large scale there should be many complications.

At a special meeting of Section C, held in the Library Hall of the Administration Building in the World's Fair, Dr. Hans Goldschmidt lectured on aluminothermics. There was no meeting of Section C on Wednesday.

The first paper of Thursday's session was presented by Dr. K. E. Guthe (National Bureau of Standards, Washington) on the "Silver Voltameter." At the conclusion of his paper Dr. Guthe emphasized that as far as accuracy and possibility of reproducing the instrument are concerned, the silver voltameter is as good as a standard cell; yet the latter may win out in the end for practical reasons. In the discussion Dr. Glazebrook gave an outline of the work which has been done in the British National Laboratory. Prof. W. D. Bancroft suggested to try a cathode inside a porous cup and the use of a rotating cathode. Mr. S. S. Sadtler suggested the use of silver nitrate as electrolyte. Prof. Carhart spoke of his early experiments in connection with this subject.

A paper, entitled "A Study of the Materials Used in Standard Cells and Their Preparation," of which Prof. H. S. Carhart and Prof. Geo. A. Hulett (University of Michigan) are joint authors, was then presented by Prof. Carhart.

Dr. Paul L. T. Héroult (La Praz, France) then presented a paper on "The Use of the Electric Furnace in the Metallurgy of Iron and Steel." He first gave a review of his work in making ferro-alloys and in reducing iron from ores, and discussed especially two methods of utilizing the electrical energy to the best advantage. He expressed the view that the electric furnace for the reduction of iron ores is applicable only under certain conditions and is not supposed to supersede the blast furnace except where electric energy is very cheap.

In the discussion which followed, Dr. J. W. Richards spoke in highly complimentary terms of Dr. Héroult's work and discussed the various special uses to which the electric furnace may be put in iron and steel metallurgy. Mr. W. McA. Johnson said that this is another example of the general rule that the electric current is most useful in metallurgy for the finishing touches.

Dr. A. E. Kennelly's and Mr. S. E. Whitney's (Harvard University) paper on the **Present Status of the Edison Storage Battery** was then read by Mr. Whitney.

This was an historical account of the development of the nickel-iron alkaline storage cells from the beginning of the work of Mr. Edison in 1898 to the present date. The first cell, named type C, was put into service in 1900; type D was first completed in May, 1903. A further modification in the cells resulted in type E, the latest type. Each type of cell is described and its performance and defects noted. The characteristics of type E are dwelt upon at some length, while its electrical theory is outlined. The results of numerous tests on the new cells are given. All of the tests show that the cells are remarkably immune from deleterious effects due to careless treatment. Cells have been allowed to dry out, have been permanently short-circuited, or even charged in the wrong direction. These cells have shown a full restoration of their capacity after a prolonged restoring normal charge. In its large output at heavy discharge rates, its low depreciation in capacity and its durability under severe adverse treatment, the cell approaches the capabilities of a piece of mechanical apparatus more nearly than is ordinarily credited to electrolytic structures. For this reason it is specially adapted to automobile service, where the treatment is abnormally arduous and severe.

In the discussion which followed, Prof. Burgess gave the results of some tests made by two of his students in his laboratory; he called attention to the fact that, in some cases, gas is liberated during the discharge. Dr. A. E. Kennelly pointed out that in this cell an approach has been made to the steel structure in dynamo construction, with respect to the number of watts per pound. The efficiency of the cell is low, but the cell is fool-proof and will stand the worst treatment.

Dr. J. W. Richards (Lehigh University) then presented his paper on "Electrolytic Conduction." In the discussion Messrs. Hering, Roeber, Patten, Bancroft and Kahlenberg participated and pointed out that the one experiment given by Dr. Richards as support of his theory would not be sufficient proof.

Prof. R. Lorenz's (Institute of Technology, Zurich, Switzerland) paper on the "Electrolysis of Fused Salts" was then read in abstract by Dr. E. E. Roeber.

The final paper of Thursday's session was Prof. W. Ostwald's (University of Leipzig, Germany) paper on "Electrolysis and Catalysis." In the absence of the author, it was read in abstract by Prof. W. D. Bancroft.

The Thursday session finished the work of Section C of the Congress, and the Friday session was, in fact, an independent meeting of the American Electrochemical Society, to which, however, the members of the German Bunsen Society and the British Faraday Society, as well as members of the

International Electrical Congress, had been invited.

At the opening of the session Dr. Hans Goldschmidt (Essen-Ruhr, Germany) presented the good wishes of the German Bunsen Society to the meeting, and Dr. J. W. Richards spoke for the British Faraday Society. The first paper of Friday's session was presented by Dr. H. E. Patten (University of Wisconsin) on "An Analytical Study of the Deposition of Aluminum from Ethyl Bromide Solutions." The paper was chiefly of chemical interest.

Prof. W. D. Bancroft (Cornell University) then read a paper on "The Aluminum Rectifier." He has used phosphoric acid as electrolyte. When the current is gradually increased, the current efficiency starts very low, about 50 per cent, and is later on pretty nearly constant, about 75 or 80 per cent. The power factor starts with 35 per cent and goes up to 90 per cent, with increasing current. The voltage efficiency is low, going down to 30 per cent.

In the discussion of this paper, Prof. Burgess referred to his investigation in which he attempted to give an analysis of the losses in the rectifier. Prof. Bancroft expressed the belief that Burgess' valve theory is not the correct explanation; he considers the valves as a source of inefficiency of the film, while Burgess believes that the whole current passes through these perforations.

Mr. W. McA. Johnson (La Harpe, Kansas) then presented a paper on "Some Aspects of Applied Electrochemistry," which was not discussed.

A paper by Mr. F. A. J. FitzGerald (Niagara Falls, N. Y.) on "The Use of Carbon for the Study of the Temperature in the Electric Furnace" was then presented. In the absence of the author it was read by Dr. J. W. Richards. The method is based on the fact that if a piece of amorphous carbon is subjected to different temperatures it changes its physical and chemical properties.

The last paper of the session was presented by Prof. W. D. Bancroft (Cornell University) on "Electrolytic Separation of Cobalt and Nickel." The method described is chiefly of chemical interest and is useful for the preparation of pure cobalt and nickel salts, although it requires considerable time.

Prof. Burgess then proposed a vote of thanks to the Organization Committee of International Electrical Congress and the meeting adjourned.

SECTION D.

The proceedings of Section D opened Monday morning with Chairman Charles F. Scott in the chair. A paper by Sig. E. Bignami on "Electrical Transmission Plants in Switzerland" was read in abstract by the secretary, Dr. Louis Bell. This paper was mainly of a statistical nature. It would appear that Swiss practice is not so uniform as in this country. The most usual frequency is 50 and there are a number of direct-current transmissions.

Chairman Scott, in opening the discussion, remarked on the large number of such installations in a comparatively small country. Dr. F. A. C. Perrine commented on the high-load factor in the Swiss plants, most of which had a load factor of over 50 per cent. This showed good management and attention to details.

Chairman C. F. Scott then announced that he had hoped to have prepared for this congress a history of long-distance power transmission in California. Since his arrangements for such a paper had failed he had himself prepared a short history of the first transmission work in this country, which he read.

The session on Tuesday was opened by the reading of a paper by Mr. J. S. Peck, on "The High-Tension Transformer in Long-Distance Power Transmission." He pointed out what an important element the transformer is in long-distance transmission and what great improvements there must have been in transformer construction in ten years when it is considered that in 1893 so little was known of insulating materials that a transformer wound for 10,000 volts involved great hazard. Now 60,000-volt transformers could be built with certainty that they would be a success. Transformers could be divided into three general classes: (1) Air blast. (2) Oil insulated, air cooled. (3) Oil insulated and water cooled. Another class sometimes used was cooled by circulating the insulating oil through cooling coils outside of the transformer. The fire risk with oil-insulated transformers had been much discussed lately. He did not consider there was much risk because the oil used was not combustible except at high temperatures. It was now common to put a very tight case on transformers to reduce the fire risk. He presented curves showing the increase in manufactured output of transformers from 1892 to 1903; also curves showing the increase in maximum and average capacity of transformers manufactured each year, and the increase in maximum and average voltages. The latter had increased from an average of 3000 volts and a maximum of 10,000 volts in 1893, to an average of 20,000 volts and a maximum of 60,000 volts in 1903. He also gave curves showing the principal characteristics of modern transformers.

Mr. F. O. Blackwell, in discussing the paper, did not agree with Mr. Peck about fire risks. He thought the storage of a large amount of oil in transformer cases was analogous to the storage of a lot of lubricating oil, for example, and as much care should be taken to isolate the oil-insulated transformers as the supply of lubricating oil for a power station. He recommended the building of a station with fireproof and airtight compartments for the transformers. Such compartments could be compared with the varnish tank compartments used in a certain factory for containing the varnish vats used for dipping coils. In case a vat took fire it had been demonstrated that it was only necessary to close the compartment and the supply of air being soon exhausted the fire would go out. He called attention to the great saving in first cost by sacrificing a little in efficiency. A transformer of 96 per cent efficiency could be obtained at about one-half the cost of the same capacity with 99 per cent efficiency.

A discussion started by Mr. E. Kilburn Scott as to whether cooling ribs both inside and outside of a transformer case would not increase the radiating ability, brought out the fact that such ribs were of no value on the inside, as the heat would pass from the oil to the metal much more rapidly than from the metal to the air. Dr. Bell said that while it was quite possible to enclose transformers completely in fireproof compartments, it was at the expense of simplicity. Much trouble might be avoided by not trying to make a station too compact. Plenty of room in a station or what might even be called waste space was frequently one of the best forms of insurance that could be carried.

Some questions were raised about securing of good oil, especially in England. Mr. Walters, of the latter country, said the only way to be sure of good oil was to purify it yourself. His company dried out the moisture by heating the oil with steam coils in a case and afterward filtering to take out impurities.

Mr. F. O. Blackwell cited a recent case where an oil did not have anywhere near the dielectric strength that it had at the factory. It was brought back to standard by pumping hot air through it. The trouble was with the barrels, which were not perfectly dry before the oil was put into them for shipment.

Mr. J. S. Peck said that transformer oil must be mineral oil bought under rigid specifications as to freedom from moisture, acids or alkalies. Oil in transit may absorb moisture.

Professor Harold B. Smith read his paper entitled "Notes on Experiments with Transformers for Very High Potentials." This was followed by Mr. F. G. Baum's paper on

High Potential, Long-Distance Transmission and Control.

After giving the equations for determining the charging current for three-phase lines and the inductance pressure due to any chosen current, the author discusses the rise in pressure due to the charging current, assuming for this purpose that the actual condensance of the line is concentrated at the centre and that the leading current which it consumes is drawn through one-half of the total line inductance. In investigating the surges produced by opening a line under load or short circuit, a similar assumption is made as to the distribution of the reactances. It is shown that, due to the series connection of the line inductance and condensance, the energy stored in the magnetic field of the conductors under condition of excess current, when the terminal circuit is opened, must pass into the line condensance and later be discharged into the inductance, the surges thus produced assuming a frequency corresponding to the square root of the product of the self-induction and capacity of the line, as is well known. The rise in potential due to the surging current is as a first approximation independent of the length of the *line*

and equal to 200 times the interrupted current in amperes.

The author describes in detail the insulator selected for the greatest transmission system in existence, that of the California Gas & Electric Corporation, which operates 700 miles of 50,000-volt transmission circuits. In the construction of the pole line, iron pins are used on all new work, and towers are considered the ideal supporters for the wires, though but few are used at present. Advantage has been taken of hills and ravines to use long spans, 1000 to 1800 feet, of aluminum wires. The general practice is to generate at 2300 volts and step up to the line voltage, the primary of the transformer being connected star with grounded neutral.

The paper drew out a lengthy discussion and much praise because of the data it gave from practical experience with the immense California Gas & Electric Company's system with over 700 miles of line and potentials approaching 60,000 volts. In concluding his paper Mr. Baum emphasized his belief that very high voltages are best for lines of 50 miles in length and are to be chosen in preference to low voltages because experience had shown them to be more free from trouble. Lightning troubles the highest voltage lines the least, and the rise in voltage caused by surging upon breaking a short circuit would be less, with the higher voltages by the formula he derived in the paper, which gave this rise in voltage as 200 times the interrupted current. The higher the voltage the less this current, therefore the less the voltage rise.

In response to questions Mr. Baum stated that the air gap on the horn type lightning arresters on a 60,000-volt line is about 4 or 4½ inches between each leg and ground, one such gap being used. A line at 50,000 volts was operated through the city of Oakland. A lengthy controversy arose over the usefulness of the horn type lightning arrester.

Dr. Perrine said the point of the paper was not lightning arresters. The important point was that we had here a great system which was free from the majority of the minor difficulties usually discussed. The use of very high voltage with small current almost wiped out the dangers of surging upon opening short circuits. In the paper no mention was made of artificial regulating drives for compensating for leading currents due to capacity or lagging currents due to induction, because with a system fed at many points and supplying current at many points as in this case, such difficulties disappear. Thus the very complexity of the system is the secret of its successful operation.

Dr. Bell agreed with this, but pointed out that the ordinary transmission was not of this class. Mr. Baum, illustrating the flexibility of his company's system, showed how, on one occasion, when the hydraulic plant at one of the power houses was being repaired, power was transmitted 350 miles, and the disabled power house being near the end of this line a generator was started as a synchronous motor to supply lagging current to counteract the condenser effect of the long line.

Mr. M. H. Gerry, Jr. thought the limiting factors of high potentials would be the accessory apparatus, such as switches, lightning arresters, etc. Mr. Baum disagreed with Mr. Gerry, as he was ready to build switches for 100,000 volts, and thought arresters would give less trouble at that voltage than at present. The line insulators limited the voltage.

Dr. F. A. C. Perrine read his paper on

American Practice in High-Tension Line Construction and Operation,

explaining in introduction that it was written with the idea of summing up American practice for the benefit of foreign members of the Congress.

In the choice of voltage it is considered best practice to use 1000 volts per mile, provided the length of transmission be not above 60 miles, since above 60,000 volts no commercial work has been regularly operated. Where direct generation at 6600 or 12,000 volts has not been resorted to, the practice is tending to the use of 2300 volts. The 2300-volt oil switch is both better and cheaper than any 500-volt switch on the market. For plants operated at less than 25,000 volts the step-up transformers are either the water-cooled, oil-filled or the air-blast type. Oil switches with either horizontal or vertical break are the standard today, no preference being given to the horizontal switch, though the author believes that in the future this type will be used as a standard for the highest potentials. For transmission at less than 25,000 volts, the delta connection of transformers is preferable; above this value star connection should be used. As regards conductor materials, the only ones at present available are copper and aluminum, preference between them being almost entirely a matter of price of transmission lines. For voltages above 25,000 no thoroughly satisfactory lightning arrester has been presented.

Thursday morning's session opened with a paper by H. W. Fisher on "Sparking Distances." This paper gave the results of extended researches by the author on the sparking distances between sharp points corresponding to different voltages. One of his efforts was to determine the methods of arranging points which would give the most uniform results. He used concave discs a short distance back of the points. He found that the sharpest points would not give the minimum sparking distance, but that points having a diameter of .003 inch would give this.

After the reading of the paper, in response to a question from Dr. Bell, the author stated that the use of ordinary commercial needles just as they come from the package is likely to introduce variation or errors of 2 to 3 per cent. C. E. Skinner spoke of the sparking method of determining very high voltages, having been formerly used in connection with insulation tests, but having been abandoned because of the errors likely to creep in.

H. W. Buck then read his paper on "Aluminum as An Electrical Conductor." He enumerated the legitimate uses of aluminum in electrical work for appliances such as bus bars, high-tension line conductors and low-tension feeders not requiring insulating covering. On account of its large cross section for a given conductivity, it is not suited to interior wiring or locations where an insulation covering is required. Aluminum is difficult to solder, probably because it is always covered with a thin film of oxide. But aluminum has now reached the place where its use is no longer an experiment. The early troubles from breaking at unexpected places have been overcome in the present stranded conductor. It is durable except when exposed to sea fog and in the neighborhood of chemical fumes, and the wire can be given a weatherproof covering when such districts are passed through. The trouble from sleet seems to be less with aluminum than with copper conductors. It costs less to transport and string than copper because it is lighter. When stringing in rough country, however, more care is necessary than with copper to avoid abrasion of the soft aluminum conductors. Soldering aluminum joints has not been found necessary.

The paper of F. O. Blackwell on

"Conductors for Long Spans"

was then read by Paul M. Lincoln, so that both the Buck and Blackwell papers could be discussed together.

The calculation of long spans is primarily a suspension bridge problem in which all of the mechanical stresses must be fully investigated. The strength of the conductor is at least as important as its conductivity, and the purpose of the paper is to give the results of investigations made by the author to determine the characteristics of conductors so as to secure some definite basis upon which to figure long spans. The available materials, copper, aluminum, iron and steel, are described from an experimental standpoint, numerous test data being given. Equations for determining the design of long spans are included, the constants depending upon the physical characteristics of the material being taken from the results of the exhaustive tests made by the author.

P. N. Nunn, in discussion, questioned whether in actual practice the deflection of aluminum spans under highest temperatures is more than copper. Aluminum conductors are most apt to be broken by arcs. In the five years' experience that the Telluride Power Transmission Company had had with aluminum on lines in Utah and Montana, he remembered but one break not due to an arc. C. W. Hutton said that in crossing valleys the California Gas & Electric Company had been trying long spans. There was one 1800-foot span of aluminum cable. There was no trouble from crossing of wires in the wind, as all conductors would swing in unison.

V. G. Converse presented a paper on "High Tension Insulators." He gave drawings and brief descriptions of the principal highest voltage insulators from 1893 to 1904. Some of the latter for 60,000 volts were 14 inches in diameter and weighed 25 pounds. Possibly the insulator of the future for higher potentials and long spans would weigh several hundred pounds. He outlined the tests which should be applied to insulators.

Chairman Scott, in discussion, said that some of the latest insulators might seem rather formidable as to size and cost, but after all the insulators are likely to be a very small item in cost of plant. One case figured on recently showed that the cost per kilowatt of plant capacity for insulators was such that fixed charges on insulator investment were only 2 cents per kilowatt capacity per year.

"High-Tension Transmission Lines" was the subject of a paper by M. H. Gerry, Jr. which was then read. Mr. Gerry at the close of his paper spoke of the discussion that had been going on regarding the relative merits of iron and wood pins. He thought there was no room for argument. The wooden pins were better because they had the practical effect, if they were properly treated, of adding that much extra insulating material in the center of the insulator and increasing the thickness of the dielectric. Of course, that part of the pin which was exposed to rain was of no value as an insulator, but the end of the pin had a value in virtually increasing the thickness of the insulator just under the wires that should not be lost sight of. He thought the burning of pins was due to a too thin dielectric at the head of the pin. Mr. Converse agreed with him on the latter point. Chairman Scott said Mr. Gerry held the record of being the first to operate at over 50,00 volts, having started such a line two and a half years ago, and that his experience was therefore of value. Dr. Perrine described an insulator something like a Chinese pagoda, which he thought designed on theoretically correct lines, which had several petticoats, each petticoat being curved outwardly so that all parts of its surface in a given plane were equally distant from the edge of the petticoat next above. This gave no one point of much higher potential stress than any other. Dr. Bell criticised some of the recent attempts to build insulators of enormous size. It was out of the question to secure good porcelain in such enormous tubs. Mr. Hutton then told of trouble with the umbrella type of insulator by the collection of salt dust from fog.

Friday morning Section D took up the paper by J. F. Kelly and A. C. Bunker on

"Some Difficulties in High-Tension Transmission and Methods of Mitigating Them."

The authors treat of pressure of over 30,000 volts and lines exceeding 50 miles in length. The greatest value of electrical tests is to determine before being used whether the various parts are homogeneous and whether they have been properly cemented together. The locality through which the line passes and the design of the insulator will determine what factor of safety must be used. Trouble from the charring of the wooden pins due to the continued leakage of current over dust-coated insulators may be corrected by placing a metal short-circuit around the pin or by the use of a metal pin. Poles should be treated to prevent decay. Every second or third season the earth should be dug away from the pole for about 18 inches below the ground line and the surface exposed should be freed from decay and be treated. The cost varies from 60 cents to $1.00 per pole. The large number of fatal accidents which have been occasioned by the telephone lines coming in contact with the power wires would warrant a separate pole line even if the series were no better. The fact that a telephone is seldom of service in times of line disturbance points to the desirability of separate pole lines.

The general subject of this and the Gerry paper being open for discussion, Mr. Bunker took exception to Mr. Gerry's ideas on wooden pins. In some places he had had wooden pins rot or mold inside of six months. In other places they would last indefinitely. Dr. Bell pointed out that wooden pins are frequently not treated properly. It was not sufficient to treat them by simply boiling in paraffine. Putting them in vacuo would take the steam out of the pins and allow the paraffine compound to enter as no amount of boiling would. What Mr. Bunker called molding of the pin was really due to brush discharge. Mr. Bunker cited his experience with a 40,000-volt line exposed to salt and marsh winds where certain insulators on wooden pins were causing as high as 60 breakdowns per month. The substitution of iron pins for wooden ones under the same insulators reduced the trouble almost to nothing. P. N. Nunn appeared as the champion of the wooden pin and the all-wood line construction as well. Some people, he said, pointed to the insulators on his Provo line and said, "Of course wooden pins must be a success with such insulators"; others pointed to the wooden pins and said, "Of course such insulators would be a success with such long pins." Practical success was better than theories. He did not know that his Utah lines ever had burned a pin save where it and the insulator were covered with alkali dust. They had operated through a drizzle with as many as 50 cracked insulators on the line. Pins were treated by placing in hard paraffine at 150° C. from 6 to 12 hours. The important part was that the pins were kept below the surface of the paraffine as it cooled. The paraffine would then be sucked clear into the center of the pin, probably due to the condensation of the vapors in the pin. The heart of pins so treated will not absorb the slightest moisture after soaking, as far as can be determined by delicate chemical balances. He took the position that if the insulator is made good enough so that it can be safely placed on an iron pin, it is good enough so that there is no danger of its burning a wooden pin. Later in the discussion he expressed the opinion that ultimately we will probably come to iron pins and steel towers, but for pioneer work such as is being done now with insulators having only a small factor of safety, we need the help of the wooden pin. Answering a question as to whether men were ever killed from contact with wooden poles, Mr. Nunn said that if a pole had become charred the men had learned that it was wise to feel at the base of the pole first, gradually working up, to test the potential existing on the pole. E. Kilburn Scott told of the necessity of using iron base poles in India because of the habit of white ants starting below the ground and eating out the inside of wooden structures, leaving only the outside shell. A barb wire wound spirally around a pole is also sometimes necessary to keep the monkeys from climbing it.

A history of "The Work of the Telluride Power Company" was then read by P. N. Nunn, chief engineer of that company, who was introduced by Chairman Scott, making a few appropriate remarks about the pioneer work in high voltages done by this company for fourteen years, this being the first presentation of it before a technical society. Mr. Nunn's paper began with an account of the company's first 3000-volt, single-phase transmission in 1890, followed by experiments on three different kinds of circuits in 1895 carried on for some time at 30,000 to 60,000 volts, during which time in the dry season 10,000 to 40,000 volts were carried on telephone insulators for about three months. These experiments gave the data upon which the first 40,000-volt line was built at Provo. This line had 76 inches between wires and pins, bringing the insulators 6 to 12 inches above the crossarms. The burning of crossarms at iron braces caused the adoption of the all-wood construction on later lines. The company now has 1,000 lines of transmission line in Utah, Montana and Colorado, and some six power stations. Many interesting historical details were given in this paper that space does not permit to be mentioned here. At the request of Chairman Scott, Mr. Nunn added a few words about the provisions being made at the new Provo plant to train employees in high-voltage work and carry on researches on matters of value to the company.

The paper by L. M. Hancock on the "Bay Counties Transmission System," and the paper by R. F. Hayward, on "The Operation of Power Plants in Parallel," were read, and after a short discussion on the latter the section adjourned.

The paper which was to have been presented by R. D. Mershon on "The Maximum Distance to Which Power Can Be Economically Transmitted," was not ready for presentation, but was read by title.

SECTION E.

This section opened on Monday morning with the reading of an interesting paper on "Improvements in Electrolytic Meters," by Mr. Arthur Wright, the originator of the well-known Wright Demand meter system; in the absence of the author the paper was read by Mr. J. R. Dick. There was no discussion of the paper, and the section passed on to the reading of Mr. Etienne de Fodor's paper on

Rates for Electricity Supply.

The author reviews in detail the causes which have led to the prices placed upon electric current used for lighting and power purposes, competition with gas having been in most cases the controlling factor. In order to effect a proper introduction of the electric motor and make its advantages known, it was necessary for central stations to offer certain inducements in the form of cheap or reduced rates for power current. From a table giving the prices charged for electrical energy in fifty cities, it is shown that the normal unit price for power current is about one-third of that charged for light. Since no restrictions have been placed as to the time when such power should be used, the electric companies have failed to recognize the logical situation. Power users see no reason why they should not demand the same rates for light as they have for power, since the light they use is also for "industrial" purposes. The author proposes to establish a unit rate for light and power, the unit rate to be divided into two classes or steps, according to the time at which the energy is consumed. Unfavorable peak loads due to the simultaneous operation of motors and lamps in the evening can be obviated by such a double-tariff system when there is a great difference between the maximum and cheaper rate.

In the discussion which ensued, Mr. Gripper said that he did not agree with the author's idea of raising the rates for power service and lowering those for lighting to equality; he thought the proper result to strive for was the lowering of power rates to such a degree as to increase the service sufficiently to make the lighting load small in comparison with the power load; then it would not be so important to get high rates for lighting, and those rates could be lowered. Mr. Arthur Williams pointed out the fact that the difference between rates for lighting and those for power is due chiefly to the difference in load factors of these classes of service; the lighting load shows the familiar sharp peak, while an ordinary power load does not—the average load is a much greater percentage of the maximum than in the case of a lighting load. Col. Crompton agreed with Mr. Gripper and also agreed with the author that the introduction of a unit scale of rates for lighting and power service could be accomplished only by decreasing the rates for lighting current; the companies in England that charge the lowest rates, he said, pay the best dividends. The average rates there are 10 cents per kilowatt-hour for lighting and 5 cents for power current. Mr. Robt. Hammond advocated rates based on a high charge for the first hour and low price for succeeding hours; the rates in a certain London plant are 14 cents for the first hour for lighting current and 8 cents for power current; for all succeeding hours, 2 cents for each class of service. He thought that Mr. de Fodor overlooked the fact that the cost of producing current includes more than the mere expense for fuel, station employes, etc., which varies roughly with the output of the station; the cost of producing a kilowatt-hour was in many cases doubled by interest and other fixed changes. Mr. Louis Ferguson agreed with Mr. Hammond's remarks concerning cost of production and with Mr. Williams as to the effect of load factor upon rates; the power load factor is so much higher than that of the lighting service that a much lower rate is practical for a given number of kilowatt-hours. Mr. Torchio elaborated the argument based on differences in load factors, illustrating his remarks by diagrams which showed the general characteristics of lighting and power load curves. Mr. J. R. Dick pointed out that simplicity of tariff rates does not necessarily give the best results, although desirable so far as it may be practicable. An analysis of operating conditions and detail results is necessary for intelligent management. He thought it impracticable to have a single scale of rates for both lighting and power current.

The next paper presented was one by Mr. George N. Eastman, delegate from the National Electric Light Association, on the subject of

The Protection and Control of Large, High Tension Alternating-Current Distributing Systems.

The principal object to be attained in the installation of protective apparatus is continuity of service. The various elements which enter into the determination of the protection needed are treated individually. In an alternating-current system the condensance performs the function of elastic ligaments, connecting the system to ground. The effect of a ground on a system depends upon the nature of the ground and the value of its reactance in relation to the condenser reactance. It is shown that a ground connection on an underground system would cause considerable more trouble than on an equivalent overhead system. In order to eliminate the chances of obtaining excessive electrostatic disturbance on the system, the proper means to employ is the permanent grounding of the neutral of high-potential systems. Ground detectors, overload relays and oil circuit-breakers are discussed, and the importance of periodic inspection and tests of all protective apparatus is emphasized.

Mr. W. C. L. Eglin said that perhaps the trouble that central station engineers fear worst is interference in underground feeders connecting the station with a sub-station. These troubles should be located just as soon as they develop and, if possible, before they actually manifest themselves, when the cable is about to break down; from Mr. Eastman's paper, it seemed that this was the point to which he and his colleagues were devoting most of their attention. The general description, of course, applied to most central stations in this country, and he would like to hear how it compared with the practice in other countries. There was, however, no further discussion of the paper, and the section passed on to the reading of Mr. Eglin's paper on

Rotary Converters and Motor-Generator Sets.

The author discusses the differences in make-up, operation and efficiency of the rotary converter and motor-generator. He shows that the rotary from an operating standpoint early indicated that the machine had a higher inherent efficiency; that the voltage and load could be easily regulated and the power factor adjusted to suit the best operative conditions of the system, and that the first cost of the outfit was comparatively low. For these reasons it was extensively used, especially for frequencies of 25 cycles. He gives tables of comparative costs and all-day efficiencies under commercial conditions and concludes that the type of machine best suited for sub-stations depends principally upon the frequency of the system and the importance of reliable and continuous service. The frequency to be used depends upon other conditions which are outside the scope of the paper. In cases where the largest percentage of the output of the generating station is to be transformed to low-tension, direct-current, 25-cycle rotary converters should be installed on account of their higher efficiency and lower first cost. The very large number of these machines which are now in successful operation proves conclusively their reliability and effectiveness. In mixed systems, and where the percentage of current transformed for low-tension distribution is small, motor-generators are desirable. With higher frequency, particularly 60 cycles, it has been shown that motor-generators compare favorably in efficiency and are much more reliable and simple in their operation.

The paper was discussed briefly by Col. R. E. B. Crompton and Messrs. Philip Torchio, M. J. Tilney and W. C. L. Eglin; the discussion brought out the facts that in England a large system using motor-generators shows an over-all efficiency from generator to consumer of 70 per cent. to 75 per cent., that starting the motor-generators on the alternating-current side is accomplished with about 60 per cent. of the full-load running current, and that in this country the preferred practice is to start on the direct-current side, which requires only about 25 per cent. of the full-load running current.

The first paper read on Tuesday was Mr. Carl Rodenbourg's, on

The Prussian System of Electric Train Lighting.

A most interesting system for obtaining constancy of illumination nothwithstanding variation of supply e.m.f., and regulation for variation in speed of the generator without special devices, is described by the author. The principle of the constant e.m.f. at the lamps with a variable e.m.f. of the source of energy is attained by the insertion of very small iron wire in the circuit of each incandescent lamp. When such a wire is connected in series with the lamp, the e.m.f. at the supply terminals can be considerably increased without subjecting the lamp to an excessive current. If the current tends to increase, the temperature of the wire increases and its resistance is considerably increased, so that within wide limits of e.m.f. the current is kept fairly constant. With a certain adjustment of resistance and lamps, a variation of e.m.f. from 56 to 86 volts changed the current taken by the lamp from 8.0 to 8.7 amperes. No such extreme change of e.m.f. takes place at the storage batteries used in the train lighting, and the variation in the illumination of the cars is not perceptible to the eye under operating conditions.

A turbo-dynamo generating unit, consisting of a short dynamo driven at 2000 r.p.m. through a 10 to 1 reduction gear by means of a 20-h.p. De Laval steam turbine mounted on the boiler of the locomotive, has given excellent satisfaction in connection with storage batteries which act mainly as a reserve. In many instances it is found desirable to drive the generator from the car axle and not from a separate steam prime mover. In order to overcome the difficulties found with automatic low-current circuit-breakers used for interrupting the current if the speed of the dynamo falls below a certain limit, there has been substituted therefor an electrolytic rectifying cell.

The electrodes of the electrifying cell consist on one side of aluminum and on the other of iron which is not soluble in the electrolyte of the cell. This cell acts as a check valve in the train-lighting system, on account of the property of aluminum which causes the insulating film formed on its surface to interrupt a current even at several hundred volts if sent through the aluminum into the electrolyte in a positive direction, but allows the current to pass almost without diminution if the direction is reversed.

In order to provide for the generation of electricity in event of the dynamos being driven in the opposite direction, there is used an arrangement by means of which the commutator brushes are carried forward until a point is reached at which the dynamo generates e.m.f. in the same direction as before. By the use of four aluminum cells in the conversion of alternating into direct current, this mechanical arrangement can be avoided.

An arrangement is in preparation for prevention of the excessive charging of the storage battery at very high speeds. The dynamo, which in general is designed as a shunt machine, is to be provided with a series coil differentially connected, so that an increase in current weakens the field and lowers the generated e.m.f.

In the discussion of the paper, Col. Crompton said that the idea that the Pintsch system is dangerous dates back twenty-two years, and is without foundation; as a matter of fact, it is so safe and simple that it has been extremely difficult to get an electric lighting system to compete with it. He had come to the conclusion that the best way to provide electric lighting on trains is to use accumulators on each car, set into a compartment under the car, and replaced at occasional stations with fresh batteries; this dispensed with machinery, automatic switches and other complications. Prof. George F. Sever outlined briefly the two general classes of train lighting systems in use in this country: the one in which a dynamo is driven from the car axle and storage cells are employed in conjunction with it, to take care of fluctuations, stops, etc., and the other involving the use of a dynamo driven by a small engine and located in the baggage car, no batteries being used. The former, he stated, appeared to have preference.

The second paper was a superb discussion by Signor E. Jona, delegate of the Italian Electrotechnical Association, on

Insulating Materials in High-Tension Cables.

The paper contains so much mathematical treatment that an abstract is impracticable.

The author's conclusions were as follows: Every insulating material has a limit of resistance to puncture; when the maximum e.m.f. per unit of thickness is exceeded, increasing the thickness of the material will not prevent a breakdown. The stress is greatest nearest the conductor, so that adding insulating material on the outside does not reduce proportionately the stress on the inner layer; hence an enormous increase in thickness of insulation would be required in order to raise appreciably the breakdown point of the covering. In order to obtain the highest resistance to puncture, the insulating covering of cables should be applied in layers of graded specific inductive capacity, the material having the highest specific inductive capacity being next the conductor, and so on, to correspond to the potential stress gradient, which, as above stated, is greatest near the conductor.

Central Station Distribution Systems.

The subject of distribution systems for central stations was covered very fully by three papers which were read in the order named, and discussed jointly: "Distributing Systems from the Standpoint of Theory and Practice," by Mr. Philip Torchio; "The Direct-Current Distributing Systems of American Cities," by Mr. Alex. Dow, and "The Superiority of Alternating Current for the Supply of Current to Large Cities," by Dr. Gotthold Stern.

Mr. Torchio's paper will be printed in our next issue. Mr. Dow's paper presented a brief history of the development of the Edison stations in Boston, Buffalo, Chicago, Cleveland, Detroit, New York (Manhattan), Philadelphia and St. Louis and described the general practice in those plants. Dr. Stern's paper was a brave but unsuccessful effort to show that direct-current apparatus has no claims for central station work in large cities. His statements were not taken very seriously in the discussion of the three papers.

Mr. Townsend Wolcott stated that all the cable insulation he had tested runs over 1000 megohms per mile, with the cable immersed in water, so that the maximum leakage through such insulation under 1000 volts would amount to an ampere-hour in 1,000,000 hours, which would be equivalent to 100 years; Dr. Stern's fears concerning electrolysis in the covering of direct-current cables subjected to high voltages, therefore, seemed unfounded.

Referring to Mr. Torchio's paper, Col. Crompton said that the operating conditions in England were different from those in this country. The largest English stations have found it advisable to adopt high-voltage incandescent lamps (200-240 volts) and to double the old voltage of their distribution systems. The lamp makers had said it was impossible to produce efficient high-voltage lamps, but the insistent demand for them had caused them to be made; the high-voltage lamps were of as good efficiency as those for 110 volts and thereabouts. This condition practically wipes out a large part of Mr. Torchio's argument, so far as England is concerned, and transfers his No. 17 hypothetical equipment from the bottom of the list to the top. Most English systems are built on this basis, except that they use motor-generators instead of rotary converters; they are now just beginning to try converters, however, being encouraged by the reports of results obtained in America with them. Mr. Torchio's method of basing his argument on a hypothetical town was wrong; no such town existed as that which was assumed in the paper. He himself had prepared, at great expense, exhaustive estimates and figures based on an "ideal" town, but he had never got his money out of them. Col. Crompton also advocated strongly the use of storage batteries, and stated that responsible companies in England were putting out batteries on a guarantee ot 6 per cent. maintenance.

Mr. Robt. Hammond, who has spent a great deal of time during the past thirteen years analyzing central station records in England, where all records must be filed with the Government, said that he preferred either straight alternating or straight direct current throughout a plant; for distances of 2½ miles or under, he would install a direct-current plant of "double" voltage (440 to 480 volts across outside wires; three-wire); for greater distances, a straight alternating-current plant. Mr. Louis Ferguson disagreed with this policy; he thought by combining alternating-current transmission with direct-current distribution the full advantages of both systems were made available and their chief disadvantages avoided. Elevator motors, he said, referring particularly to Dr. Stern's advocacy of induction motors, must be direct-current for high car speeds; at 250 feet a minute or over, the induction motor was impossible.

Mr. Arthur Williams pointed out that lighting standards in England were not quite so high as here, which possibly accounts for the indifference to high-economy lamps. The American central stations take the ground that they sell *light* as distinguished from selling merely current, and it is not expedient to allow customers to purchase their own lamps unrestricted. Mr. Torchio, closing the discussion, said that the conditions described in his paper are not "ideal," but are to be found in most American cities of smaller size; his method, therefore, was correctly founded from the practical viewpoint. Referring to high-voltage lamp efficiency, he said that four or five years ago such lamps in England ran as high as 7 watts per candle, and he thought Col. Crompton must have in mind 3.5 watt lamps in saying that high-voltage lamps were now as efficient as those for the ordinary voltages.

The final paper of the day's session was Mr. Louis A. Ferguson's, on

Underground Construction,

which the author read in abstract.

Electric companies in the United States are practically committed to the drawing-in system of cables and conduit, and it is to such a system that this paper refers particularly. What is commonly known as the Edison "tube system" has been in the past used extensively for low-tension work, and it is still used to a limited extent, but on account of the relatively short life of the tube and the higher cost of repairs, its use in late years has greatly diminished. The principal advancement during the past ten years has been in the more general use of paper insulated cable as compared with rubber, the manufacture and installation of cables for extremely high voltages, the doing away with wood pump log and other inflammable material for conduit work, and a more stable character of construction in general. The next ten years will probably see underground cables worked at much higher voltages than those now used, possibly different material used for insulation purposes, and better methods of protecting underground cables.

The paper was discussed by Messrs. Arthur Williams, Taite, Crompton and Ferguson. Col. Crompton thought the method of making connection between overhead and underground lines which was described in the paper was inadequate. In Calcutta he had had great trouble from inductive discharges of a surging character at this point and had found it advisable to provide substantial hollow pillars to contain the connector tablets, and to furnish arresters and hand switches between the overhead and underground circuits. In London, he had had to provide much better ventilation at manholes than was described in the paper, in order to guard against accidents due to gases. He said that in certain parts of his company's system of distribution he used bare strap copper conductors, mounted on porcelain insulators, the latter being located in manholes at short intervals. The conductors were insulated from the duct walls only by air. In 17 years the maintenance had averaged only one-third of 1 per cent.

There was no session of this section on Wednesday, this being "Electricity Day,' 'on which the annual convention of the American Institute of Electrical Engineers was held at Festival Hall, in the Exposition grounds. At this convention, a paper was read by Col. Crompton on "Standardization of Dynamo Electric Machinery," which paper was discussed at Thursday's session of Sections B and E jointly. The first paper taken up Thursday was one by Prof. Clarence Feldmann and Mr. Josef Herzog on

The Distribution of Voltage and Current in Closed Conducting Networks.

The authors assume first the single case of current being supplied to a single receiver over power lines from two points at separate difference of potential·and show that the final current distribution may be regarded as the superposition of the partial distributions, one with load and equal potentials, the other with no load and the assumed unequal potentials. This same principle of superposition may be applied in whole net-works if different voltage or current consuming devices be applied successively. For studying net-works the authors resort to the method of transformation of the net-work or other parts in such a manner that the current and voltage distribution in the rest of the net-work remains unaltered. In most of the practical cases the net-work may be split up into such parts as by themselves may be completely treated by the method of transfiguration.

The paper was discussed briefly by Messrs. Lieb, Crompton, Kennelly and Junkersfeld. Messrs. Lieb and Crompton said that their respective companies had started out with the plan of laying out a model of the distributing system and carefully computing the distribution of the load on the mains, and therefrom, the size of the mains, but this had been later found unnecessary. The better plan is to lay down uniform standard-sized mains with a view to the probable increase in load in the immediate future, and to start with feeders sufficient to supply the mains, adding feeders according to the distribution of the load that developed in actual practice; in this policy Mr. Junkersfeld concurred. Dr. Kennelly said that the paper conferred the advantage of simplifying the calculation of mains and supplied a physical means of working out a mathematical problem.

The Electric Arc

was the title of the next paper, which was read by Dr. Charles P. Steinmetz. In it, the author presented briefly the characteristics of arcs between different kinds of electrodes and described some extremely interesting investigations of the mercury arc stream and the magnetite or flaming arc which had been carried on in the General Electric Company's laboratory. The familiar arc between carbon electrodes is not a typical electric arc; carbon has been used so largely probably because of its ready volatilization and the fact that it is the only material that will maintain an alternating-current arc at a relatively low difference of potential. The typical arc in air is that between iron and copper or their conducting oxides; the typical vacuum arc is the mercury arc stream. Magnetite electrodes and the mercury arc stream both act as rectifiers under ordinary conditions. In order to produce a true alternating-current arc stream in mercury vapor, 9000 volts are required; at lower voltages, every other half wave is suppressed, the current being unidirectional. The range of rectification is that between the direct-current e.m.f. that will maintain the stream or arc and the alternating e.m.f. that will strike across the gap when no arc exists.

In the absence of the author, Dr. Louis Bell read a paper by Prof. A. Blondel on

Impregnated Arc Lamp Carbons.

in which the author reviewed the development of the Nernst lamp and the mercury arc and led up to the different classes of electric arcs, the characteristics of which he described. He discussed at some length the investigations that had been made with mixed electrodes—carbon combined with various salts—and summed up the salient characteristics of arcs between electrodes of mineralized carbon, hollow and cored carbon, and his own form of electrode consisting of mineralized carbon within a thin sheath of pure carbon. The following table of comparisons was given:

Kind of arc.	Watts.	Mean hemispherical candle-power.
Ordinary open arc between carbons....	495	700
Enclosed arc between carbons	768	329
Steinmetz's magnetite arc	385	400
Bremer arc, inclined carbons; 9 amp...	495	4814
Blondel carbons; 9 amperes	500	4800

In the discussion of Dr. Blondel's paper, Mr. Lieb mentioned trials of the Blondel lamp in comparison with enclosed arcs, in which a 200-watt 3-ampere Blondel lamp showed better diffusion and effective illumination than a 500-watt enclosed-arc lamp using the usual type of carbon electrodes. Dr. J. P. Jackson said that an equipment of magnetite arcs in Harrisburg showed equal illumination with 9.6-ampere open arcs at distance 20 per cent. to 30 per cent farther away from the lamp; the magnetite lamps take 320 watts. Prof. E. L. Nichols said that comparison between artificial illuminants of the types now being developed was impossible by means of ordinary photometry on account of the selective radiation involved, and said that some other means of comparison must be devised before the relative merits could be determined. Dr. Steinmetz pointed out that high efficiency alone is not the commercial criterion; long life of electrodes and other operative conditions modified the matter very greatly. The titanium arc shows the highest efficiency of any, requiring about 0.15 watt per candle, but it does not meet commercial requirements.

Section E then joined Section B in the discussion of Col. Crompton's paper on standardization. The old question of frequency was the chief topic, the English standard proposed by Col. Crompton being 50 cycles, while the American standard of that order of magnitude is 60 cycles. The consensus of opinion was to the effect that there is too large an amount of 60-cycle apparatus in use to permit changing to 50 cycles in America; that as there were several frequencies in use in Europe it would perhaps be possible to get 60 cycles adopted there, but that the matter is chiefly one of commercial importance, so that engineering conclusions would have little weight. Profs. Steinmetz, Ascoli and Crocker, Col. Crompton and Messrs. Lieb, Scott, Gray (president British Institute) and Glazebrook participated in the discussion. Prof. L. Lombardi then read his paper on "Stroboscopic Observations of the Arc," which it is impracticable to abstract on account of the large number of photographs used to illustrate, and necessary to an understanding of, the paper; these were not available for reproduction. In discussing the paper, Dr. Steinmetz said that the observations of Prof. Lombardi bore out completely his own deductions from investigations recently made. He also pointed out that the mercury arc stream acts as a rectifier of alternating current between 6000 and 9000 volts, even with symmetrical electrodes; the direction of the rectified current is purely accidental, he said, depending on which half wave the arc stream happened to start with, but after starting, it maintained the current absolutely unidirectional.

Prof. E. L. Nichols' paper on "Standards of Light" was read by title. There was no discussion of it.

Friday's session opened with the reading of a paper by Mr. Gerhard Goettling, delegate of the Association of Edison Illuminating Companies, on the subject of

Storage Batteries as an Adjunct to Central Station Equipment.

The paper gives an outline of the present methods of installation and operation of storage batteries as practiced by the Edison Companies in the United States. The battery plates, as now furnished, show great improvements over those of previous years. The positive consists of a rigid conducting support, holding in place soft lead buttons of coiled ribbon with corrugated surfaces, these buttons extending slightly beyond the surface of the grid. The negative plate now consists of a hard metal supporting grid in which the various sections of active material are securely held in place by means of a thin covering of perforated lead. An important development is the substitution of thin wooden diaphragms between the plates as separators in place of the glass tubes heretofore generally used. This new separator effectively prevents any possibility of short circuits forming between the plates, thus keeping the cells in uniform condition, and resulting in a very considerable increase in the life of the plates.

The paper was discussed briefly by Messrs. Crompton, Lieb, Hammond, Junkersfeld, Tilney and Goettling. Col. Crompton pointed out that the life of a battery was determined by the life of the end-cells, and thought that on that account regulation by means of a reversible booster was preferable to the use of end-cell switches; he described in some detail the arrangement made in England for guaranteeing battery maintenance to stations purchasing batteries.

Mr. Lieb said that with the modern system of alternating-current generators, high-tension transmission and converting sub-stations, batteries are indispensable as auxiliaries in order to insure absolutely continuous service. Mr. Hammond explained that the maintenance contracts in England covered the care of tanks, plates and everything else, except the flooring under the batteries.

In the absence of the author, Mr. Henry Noel Potter's paper on

Nernst Lamps

was read by Mr. Percy M. Thomas. The author reviewed the development of the Nernst lamp in Europe and this country, and pointed out the differences between the European and American practices. He also briefly explained the characteristics of Nernst lamp glowers, ballast resistances and heaters, and described in detail the present American practice in the construction of these lamps.

The discussion of the paper, which was participated in by Messrs. Jorge Newbery, R. Hammond, George Wilkinson, A. C. F. Webb and Arthur Williams, did not bring out any unfamiliar points.

Steam Turbines.

A group of three papers was then read, one by Mr. W. L. R. Emmet, on "The Effect of Steam Turbines on Central Station Practice"; one by Professor Rateau, entitled "Notes on Steam Turbines Operating with Fall of Velocity," and one by Mr. Francis Hodgkinson on "Steam Turbine Performance."

Mr. Emmet in his paper presented the usual arguments in favor of the steam turbine, and also suggested that there was an excellent field for this apparatus in the use of exhaust steam from reciprocating engines, and also in operating on steam of low pressure obtained by delivering the jacket-water of gas engines to a boiler, and heating by means of the exhaust gases from the engines. The output of a reciprocating engine plant, he claimed, could probably be increased as much as 30 per cent. by the introduction of low pressure turbines with proper condensing facilities, and without any increase of fuel consumption or change in the boiler plant; used in conjunction with gas engines in the manner stated he thought that a similar increase in the output of the plant could be attained.

Professor Rateau's paper consisted of a mathematical analysis of different types of steam turbines, in the course of which he drew comparisons between turbines operating with a fall of steam velocity and those operating with drop of steam pressure. The former type, he said, could be designed to give low speeds, and would therefore be highly advantageous, but they were too uneconomical, showing 28 per cent to 44 per cent. lower economy than turbines of the multicellular type operating with drop of pressure. His paper contained a diagram plotted by means of formulas given in the paper, and showing that the drop of velocity type gave a maximum efficiency with the bucket speed about 30 per cent. of the steam velocity, while the multicellular drop in pressure type increases in efficiency as the ratio of bucket speed to steam velocity increases. The relation between the efficiencies of the two types, as shown by his diagram, is as 65 to about 74 at the speed ratio corresponding to the maximum efficiency of the drop in velocity type.

Mr. Hodgkinson's paper consisted chiefly of tabulated results of a large number of tests of recently built Westinghouse-Parsons turbines, most of which were also given graphically by means of diagrams. The author explained briefly the general principle of the Westinghouse-Parsons type of turbine, in the course of which he brought out the point that three barrel diameters were used merely for mechanical convenience; if only one diameter were used, the vanes nearest the steam inlet would have to be unmechanically small, or else those through which the steam passed last before exhausting would have to be unmanageably large. He also stated that each inch of vacuum beyond 25 inches will increase the economy of the Westinghouse-Parsons type of turbine by about 3 per cent. to 5 per cent.

Integrating Meters.

A paper by Mr. Caryl D. Haskins on "A Study of Integrating Electric Meters" and one by Mr. George R. Green on "American Meter Practice" were next read and discussed jointly. Mr. Haskins' paper consisted of brief descriptions of the various types of meters, namely, electrolytic, thermal, clock, relay, variable transmission and electrodynamic, the last-named class including, of course, the well-known motor type of meter. Mr. Green's paper was restricted to the consideration of the commutator and induction types of motor meters, and contained practical suggestions as to the proper selection, installation and care of meters, together with remarks concerning meter reading and tests.

In the discussion of the two papers, Mr. Dick said that in England the ampere-hour meter was used very generally, and was considered as good as the watt-hour type because the voltage fluctuations compensated each other, so that the average voltage was practically equal to the rated voltage of the circuit. He strongly favored the electrolytic type of meter, chiefly because of its simplicity and accuracy at all loads. Mr. Eglin pointed out that the ampere-hour meter even on direct-current circuits is not strictly accurate, on account of voltage variations, and it was grossly inaccurate on inductive alternating-current loads for obvious reasons. He said that in direct-current work, a practical objection to the electrolytic meter was that the customer could not read his meter; this was one of the strong reasons for discontinuing the use of the old Edison chemical meter.

A paper by Mr. Poulsen on "Producing Continuous Electrical Oscillations" and one by Mr. Horace F. Parshall on "The Yorkshire and Lancashire Electric Power Companies" were read by title.

The sections combined on Saturday, September 17, in general session at Congress Hall, Exposition grounds, where the closing exercises of the Congress were held.

SECTION F.

The first paper presented on Monday was that of Philip Dawson, entitled "Electric Traction on British Railways." Mr. Dawson sketched the conditions of electric traction in Great Britain and pointed out that electricity is the only hope there of suburban and short distance interurban systems.

In the discussion of Mr. Dawson's paper, Mr. H. Ward Leonard said that the important advantage of electricity over steam traction is that it will give maximum ton miles per mile of track. He did not consider that too much stress should be laid on comparisons with steam roads on the cost of wages or cost of fuel, and cited the case of the Pennsylvania Railroad, where both of these items during the past year have very largely increased, while the cost per ton mile has been reduced from 1.6 cents per ton mile to .36 cent. Mr. Sprague said that it should not be forgotten that the great success of the electric railway thus far has been in services requiring frequent stoppage. In applying electric traction to steam lines the primary consideration is the density of traffic, and he considered that so long as it was a question of sending out high power units at long and irregular intervals over great distances we might as well be frank and say that this is not a field for electric transportation. He considered that there were many other questions to be taken up and considered before that of the operation of trunk railroads by electricity.

The final paper of the session was that of J. B. Entz, on "Storage Batteries," which treated of the application of batteries to railway service. It was pointed out that economies may be achieved in the use of batteries at power stations through the improvement of the load factors of both the generating and transforming apparatus; their use would also reduce the capacity of machinery required for carrying the peak load. It is estimated that the total gain from the use of batteries may be 15 to 20 per cent. The author also discussed the subject of boosters in considerable detail and concluded his paper by the presentation of the details of the proper construction of a battery for railway service. He considered that the positive plates should be of the Planté type and the negative plates of the pasted type. In the discussion Mr. Sprague said that he favored very strongly the use of storage batteries in the New York Central electric system, particularly to reduce the size of sub-station equipment and partly to provide a reserve. Mr. J. S. Edstrom, of Sweden, said that in Europe, where the railway plants are much smaller than in this country, storage batteries are considered a great advantage, and this is particularly true of lines running but a few cars. In Europe batteries are guaranteed that at the end of ten years they will have the same capacity as when installed. Mr. Sprague said that the great size of some of our railway electric systems gave rise to conditions quite different than in Europe and rendered it inadvisable to use storage batteries in main power stations, though they would be advantageous in sub-stations.

Section F held a joint meeting on Tuesday with Section B, the proceedings of which are reported under that section. The proceedings of the joint session of the American and British Electrical Engineers will be found elsewhere in this issue.

On Friday four papers were read in abstract. The first was a paper entitled "The Mono Rail," by F. P. Behr, which was also presented before an audience in the Westinghouse Auditorium in the World's Fair Electricity Building. Mr. Behr built the first railway of this type in Algiers in 1883 and the second in London in 1886. A mono-rail system was constructed between Listowell and Ballybunion, in Ireland, and a high-speed mono-rail road is now being constructed between Manchester and Liverpool, a distance of 31½ miles. A speed is reached of 110 miles an hour, and each train consists of one car carrying from 40 to 85 passengers. The second paper, by Dr. Rasch, on "The Railway Booster," treated the subject largely from a mathematical standpoint. A paper by F. J. Sprague, on "The History of the Electric Railway," gives an account of the development of electric traction from the day of Davidson up to the present time and enters quite fully into the details of the multiple unit system. Mr. L. B. Stillwell, in a paper entitled 'The Wilkesbarre & Hazelton Railway," gives an account in detail of this railway, which is the first equipped in this country with the protected third rail.

At the opening of the session on Friday Dr. Louis Duncan read an abstract of his paper on the general subject of the application of electricity to railroads. He sketched the manner in which electric traction had displaced the horse railway and won its way for elevated and interurban service. In the heavier electric traffic the success has been due to the fact that the load factor in the generating station, where the losses are greatest, has been brought to a reasonable figure, the load factor at the sub-stations not being so important. Dr. Duncan considered that we can offer very little to trunk railroads with respect to decreased expense and increased facilities of operation, and that we are not in position to offer for general railroad work any particular advantage for electricity over steam. There are, of course, special cases in which electricity has tremendous advantages. Mr. Sprague considers that there is an absolute bar toward any system of electrical operation which requires more than one conductor overhead. He thought that if experiments demonstrated anything it was the impracticability of running trunk lines on the polyphase system. He considered that the single-phase motor had objectionable features, and that the direct-current motor, with respect to weight, efficiency, simplicity, reliability and perfection, is superior to the alternating-current series motor. Mr. Lamme contested Mr. Sprague's statement as to the superiority of the direct-current motor, and said that the alternating-current motor admits of the use of more current voltage in its windings, thereby eliminating troubles to which the direct-current motor is subjected. He did not anticipate any particular difficulty in applying the alternating-current motor to railroad work, and did not apprehend any danger from higher trolley voltage since it could not have any effect beyond the frame of the motor. Mr. E. Kilburn Scott defended at length the polyphase motor for traction purposes, which he considered to be superior to any commutator motor for this purpose. He stated that in Italy the three-phase motor had achieved magnificent success in the service. Mr. Ward Leonard sketched the characteristics of his system of railroad traction, consisting in transmission to a train of high tension single-phase alternating-current driving on the train a single-phase motor direct-connected to direct-current generators supplying the train motors. Mr. B. J. Arnold said that he did not consider there would be any difficulty in using 600 or 700 volts in single-phase motors, and considered the use of low voltage in such motors undesirable from the standpoint that low voltage current must be frequently broken. He maintained that the polyphase system with its two wires overhead was impracticable for railroad work. Mr. Henry Pickler pointed out that the polyphase motor has and is giving excellent service in railway traction, though no one would think of using it where stops are frequent. He considers that the two variations of speed which it admits of, that is, high speed and half speed, are entirely satisfactory for many conditions of railway service. Mr. H. Armstrong said that his company had given very thorough study to the subject of polyphase traction. The chief objection to its use is the motor constant speed characteristic, the restricted output of the motors and the poor power factor. The constant speed characteristic is particularly objectionable in the case of grades. On the other hand, the commutator alternating-motor is especially adapted to railway work and it comprises most of the characteristics wherein the three-phase motor is deficient. Mr. Eck, referring to several references to the loss in the rail through the use of alternating-current, said that such loss is less in alternating current at 1000 volts than in direct current at 500 volts. Mr. Steinmetz stated that his company had experimented for more than ten years with polyphase railway motors and that they could never honestly recommend a customer to install a system employing this motor. It is true that a polyphase induction motor is a very beautiful apparatus when run at constant speed; it is possible to run it at half speed by a certain arrangement of two motors, but this method is not satisfactory. He also considered very objectionable the use of two wires, which are necessary in the polyphase system. Referring to the Leonard system he said that he fully agreed with the statements made as to its beautiful control of speed and power; this, however, is not the problem of electric railway service, where the chief conditions are quick acceleration, efficient running at high speed and quick stoppage. It is not desirable to run at any low speed continuously; what is needed is a railway motor system as simple as possible. The single-phase commutator motor gives a high efficiency of operation under normal conditions.

SECTION G.

On Monday but two papers were presented, those by Mr. Saitaro Oi, of Japan, and Mr. Joseph Hollis, of Hungary. Mr. Francis W. Jones, chairman of the section, referred to the great progress in Japan of telephony and telegraphy and remarked that the work of the Japanese along these lines is both very methodical and very complete. The paper by Mr. Hollis described the application in Hungary of a system of simultaneous telephony and telegraphy using complete metallic circuits. This system does not appear to differ essentially from the usual Van Rysselberghe system. Mr. Hesketh said that in Australia a ground circuit and not a complete metallic circuit is used for simultaneous telegraphy and telephony. A system also in use in Australia is where two telephone circuits are operated over three metallic conductors. Major Reber said that in the army the grounded circuit for simultaneous telephony and telegraphy had been used with success. Mr. Gherardi called attention to the fact that such a system is also employed on some railroads.

The first paper presented on Tuesday was that of Dr. Kennelly on "High Frequency Telephone Tests." This gives a method for making measurements and tests of precision of telephone circuits and apparatus in cases where previously only crude methods had been used. In the discussion Dr. Kennelly said there is no benefit to be derived from loading short lines with inductance. Mr. Gherardi referred to the interest and value of Dr. Kennelly's paper and said that it will serve a useful purpose through giving methods of testing lines which will give evidence of their condition directly. Mr. Hesketh said that the paper presented a most valuable and practical method of testing telephone lines under practical working conditions, and that a great need had existed for such a method.

Mr. John Hesketh, of Australia, then presented his paper entitled "A New Danger to Lead Covered Aerial Cables." In the discussion Mr. Hesketh said that cables were attacked whether the lead sheathing were bare or taped. Mr. Wotton said that considerable trouble had been experienced in the South with an insect which bored through the lead sheathing of the cable. Mr. Green spoke of a case where gray squirrels attacked the lead sheathing of cables. Mr. Gherardi said that no damage from insects had yet been discovered in New York or vicinity. Mr. Jones said that there had been frequent reports concerning damage done to cables through perforations; these had been ascribed to sportsmen making marks of the cables, but it might possibly be that in some cases an insect was the cause.

The next paper presented was that of Major Samuel Reber, U. S. A., on "The Telegraph, Telephone and Cable in War." In reply to an inquiry by Lieut. Com. J. L. Jayne, U. S. N., Major Reber said that the operation of wireless telegraphy over long distances had not proved successful for military purposes, though the opposite was the case for short distances up to 35 miles. The telephonic receiver is much better for field work than the coherer. At the conclusion of the discussion of Major Reber's paper Mr. P. B. Delany presented his paper on "Rapid Telegraphy." Mr. F. W. Jones said that in comparisons as to the conduct of the telegraph in different countries it must be borne in mind that in this country the telegraph is operated as a private enterprise and not as a State department. In the latter case there is apt to be no recourse in case of error for damages, while the reverse is the case in this country.

The next paper presented was that by Dr. Louis M. Potts, entitled "Printing Telegraphy." This includes an account in brief of the various recent systems of printing telegraphs that have been put before the public. This was followed by a paper by Prof. Ferdinand Lori, of the University of Padua, describing a harmonic rapid telegraph invented by the author which, it was stated, had given very favorable results on experiment. This paper was read by title, and then Mr. F. J. Dommerque read his paper on "Telephone Problems in Large Cities." This paper deals with the complications introduced by the ever-extending service of large cities, and advocates as a partial solution a combination of the manual and the automatic systems, the latter being used for trunking and the manual for other work. Mr. John Hesketh said that between the one-office system and the multiple system there is a mean which is to be determined by local conditions in each case. Mr. Dommerque, in reply to an inquiry, said that in four-division work the percentage of mistakes is perhaps 40 per cent. When the wrong call comes in, or a call on the wrong board, the operator transfers it to the transfer table, where the line is connected to the right operator. The serious trouble to contend with is that sometimes the subscriber pushes the right button, and, not getting a response immediately, pushes the second, third or fourth button, thus calling several operators at the same time.

Mr. Gherardi said that at St. Louis about 50 per cent of the calls are being trunked. He did not believe that a sub-divided switchboard would diminish the trunking percentage very materially. Mr. Hesketh did not think that anything affecting the reliability of the telephone operation should be left to the subscriber.

The discussion of Mr. Dommerque's paper was resumed at the session on Friday, when Mr. H. Lincoln Reber, in reply to a question as to the total amount of trunking from section to section in the St. Louis multiple exchange, said that it amounts to one-half of one per cent, and 8 per cent of this was due to the subscriber, and 12 per cent to the equipment. He described how the trouble was overcome in practical operation.

The next paper presented was that by Mr. J. C. Barclay on "Modern High Speed Printing Telegraphic Systems." This was followed by a paper entitled "Automatic vs. Manual Telephone Exchanges," which, in the absence of the author, Mr. Kempster B. Miller, was read by title. This paper discussed the present status of the automatic telephone exchange and gave very encouraging opinions as to its future. The author not being present at the meeting, the discussion of his paper was taken up on Friday, and was quite extensive. Those taking part were Messrs. Miller, Dommerque, Gherardi, Delany, MaNaier and Major Reber. In the discussion Mr. Miller upheld the cause of the automatic exchange, which was subject to criticism by the other speakers, with the exception of Mr. Delany, who considered that the present system of automatic telephony gave very little indication as to what the outcome of the future would be, and Mr. McNaier, who thought that in the time to come, when every house would have at least one telephone, the automatic exchange will be perfected in order to handle the conditions this situation will bring about.

The session on Thursday was devoted entirely to wireless telegraphy. The first paper presented was by Marquis Solari, entitled "Wireless Telegraphy of the Italian Government," which included a very complete historical and technical description of the Marconi system. The next paper was that of Mr. John Stone, entiled "Theory of Wireless Telegraphy." This paper deals largely with the system of selective wireless telegraphy with which the name of the author is connected. Dr. Lee De Forest then read his paper entitled "Electrolytic Receivers in Wireless Telegraphy," in which he gave the history of the electrolytic receiver and discussed at length the nature and theory of its action.

The next paper on the programme was that of Prof. J. Fleming, on the "Present State of Wireless Telegraphy," which was read by title. This paper gives a very complete account of the Marconi system from its inception to the present day.

The paper of Mr. Hammond B. Hayes, entitled "Loaded Telephone Lines in Practice," was next read. In the discussion Dr. Kennelly spoke highly of the value of the paper, not merely from the practical, but also from the theoretical standpoint. Mr. Stone referred to the serious loss which occurs when the current passes from the overhead line into the cable, or from the cable into the overhead line, and said that to overcome this it is practically sufficient to determine upon a certain ratio between the inductance and capacity of the overhead line and the inductance and capacity of the cable. Mr. Gherardi said that the cables crossing the North River, New York, had inductance coils at each end.

The first paper read at the session on Friday was one by Mr. M. G. de la Touanne, entitled "Theory of Telephone Exchange." A joint meeting was then held with Section F of the Congress, at which a paper was presented by Prof. G. Sever, entitled "Electrolysis of Underground Conductors," which treated of the question exhaustively and largely with reference to the results of electrolytic surveys. In the discussion Mr. Hesketh pointed out that the injurious results of electrolysis cannot possibly be considered as chargeable to only one party, and its avoidance must be by mutual arrangement. It is impossible for a telephone company to protect its lines by any known reasonable methods, if the railway companies on their part neglect well-known methods. He favored measuring the difference of potential between the rail and the earth nearest to the rail as the more correct method. Prof. F. C. Caldwell said that the amount of damage from electrolysis would depend very largely upon the nature of the surrounding soil. In some tests with the soil from Dayton, Ohio, there was a large amount of electrolysis, while the soil at Columbus gave very small amount. Mr. Harrison said that it does not matter practically how much current flows in the pipe, for a very considerable length the line may be a fair insulator, and there will then be a patch which is conductive to a high degree, and here the current density and damage will be greatest. Prof. Sever said that in New York the sheaths of some underground cables were bonded to the elevated structure by copper wire, and that 1500 amperes passed through the wire. In spite of precautions taken in New York telephone cables these convey very large currents, even amounting to thousands of amperes. Mr. Gherardi said it was not unusual for currents of several hundred amperes to flow in the sheathing of telephone cables, and that the aggregate amount of the current carried in New York telephone cables amounts to thousands of amperes. Notwithstanding this, through coöperation of the street railway people, they had succeeded in taking care of the situation, so that it does not constitute a serious difficulty to telephone service. He considers that with the assistance of railway companies the trouble from electrolysis may be reduced to such a point as not to be a vital question. Prof. Sever described precautions taken at Richmond, Va., to avoid electrolysis. Four points were selected almost at the corners of a rectangle, and very heavy return feeders carried from these points directly back to the power house; the tracks were also heavily bonded, and the problem by this method seems to have been solved. Prof. Sever said that in Brooklyn a lead pipe had been taken up, part of which had entirely disappeared through electrolytic action. Mr. J. S. Edstrom, of Sweden, said there had been very little trouble in Europe from electrolysis, which he assigned to the very solid construction there, both with respect to bonding and cables carrying return current to the power station. In Berlin no more than two volts difference of potential is allowed between two points on the rails in a city system, and this rule has been adopted in most German cities and in Switzerland and Sweden. In Sweden there are two heavy copper wires at each joint, and the rails are bonded between each other and also the double tracks at certain intervals. At bridges or in passing over water piping the rails are insulated with asphalt as much as possible. The rails in the street are generally insulated by means of a layer of concrete under them. The return feeders are generally of the same dimensions as the outgoing feeders. He did not, however, consider that the two volts of drop allowed is sufficient. Mr. F. W. Jones gave the experience of the Postal Telegraph Company with respect to electrolysis since 1880. In most cities where underground telegraph cables were laid parallel with, or near to electric railways, sections were eaten and the service stopped. It was found, however, that by securing a good return wire from the points at which the currents were leaving the cable sheaths, back to the railway generator, the underground system was rendered entirely immune. There has been no trouble since this remedy has been applied. As a matter of fact, the telegraph company loans the sheaths of its cables to the railway company to allow it to get the current back to the generating station, the sheaths being bonded to their return wire, and by this means damage to the cables is avoided. He doubted whether there is any serious electrolysis caused by telegraph currents.

Mr. L. W. Stanton presented a paper entitled "Modern Telephone Engineering," which was read from manuscript. The final paper of the session was that read by Mr. J. C. Kelsey, entitled "Two-Strand Common Battery System." In the discussion Mr. Dommerque said that the two-wire system described renders it possible to build boards having 18,000 lines connected. The system was developed by Mr. Dunbar and Mr. Miller, and has given excellent service wherever it has been installed. Mr. McBerty said that the advantage of the two-wire over the three-wire system would not be established until switchboards were called for exceeding the capacity of the three-wire system, and this he said had not yet been done; otherwise the three-wire system would still have the advantage.

JOINT MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS AND THE INSTITUTION OF ELECTRICAL ENGINEERS OF GREAT BRITAIN.

At this meeting, President B. J. Arnold, of the American Institute, delivered his annual presidential address, in which he reviewed briefly the progress that had been made in electric traction and expressed optimistic views as to the future of that branch of industry. On motion of President Gray, of the British Institution, and Col. R. E. B. Crompton, past president of that Institution, the members present tendered Mr. Arnold, by acclamation, a hearty vote of thanks for his address.

The subject for discussion at this meeting, "Different Methods and Systems of Using Alternating Current in Electric Railway Matters," was then taken up, Dr. Charles P. Steinmetz opening the discussion. Mr. Steinmetz reviewed at some length the development of the alternating-current railway motor, starting with the early work of Messrs. Rudolph Eickemeyer and Charles Vandepoele, and leading up to the latest type—the compensated commutator motor. He discussed the characteristics of the direct-current series railway motor, the polyphase induction motor, and the commutator alternating-current motor, and their adaptability to different classes of railway work, these classes being ordinary city street service, rapid transit service, as on elevated and underground tracks; suburban and interurban service, trunk line passenger service and long distance freight service.

For city service the characteristics of the direct-current series motor are best on account of its enormous torque at starting, its rapid acceleration, and maintenance of torque from the limit of acceleration to the free running speed. These features were absent in the induction motor. This latter type of machine cannot combine very high acceleration with high efficiency at free running, or with the ability to run efficiently at low speeds. The alternating-current commutator motor, however, while having not quite such good characteristics as the direct-current series motor, is well adapted for city service. The problem and conditions in rapid transit service are the same as those in city service except that the units are larger, the speeds higher and the stops are not so frequent.

In interurban and suburban work there are fewer stops, so that rapidity of acceleration is of less importance and a lower torque of acceleration will do, but the same surplus torque is required as in city service, because the voltage cannot be maintained so nearly constant on interurban lines as in the city. The induction motor being most sensitive to voltage variation (the torque varying as the square of the voltage) is not at all adapted to interurban and suburban service, the maximum torque which the motor can give cannot much exceed the acceleration torque without spoiling the characteristics of the motor, and while the motor will run at constant speed regardless of voltage fluctuations, an excessive drop in voltage will cause it to "break down" and refuse to carry the load. The alternating-current commutator motor, however, appears to be pre-eminently constituted for this class of work.

In trunk line passenger service, the rate of acceleration at present obtained by means of steam locomotives is much lower than that obtained in everyday practice for electric railways, and as excessive acceleration torque does not need to be sustained up to high speeds in this class of service, it is a field where alternating-current commutator motors should be employed, and possibly induction motors if the question of voltage maintenance does not interfere.

In trunk line freight service the same considerations come in, except that the speeds are relatively low and the train weights are enormous, so that here more than in any other class of work it is essential to have a very large surplus torque available in order to start the train or to hold it on an up grade. For this service, therefore, as in interurban service, the motor must run efficiently at light loads and be able to give a very high torque, although it need not carry this torque up to high speeds.

Mr. Steinmetz then pointed out that on account of the enormous mileage of direct-current railways already existing in cities, this type of equipment would always remain; consequently, long distance motors, that is to say, motors running over connecting links between different city systems, must be able to operate on the direct-current system. The alternating-current commutator motor is highly advantageous since it possesses this peculiar characteristic. He also expressed the opinion that since 25 cycles had been adopted as the lowest alternating current frequency in this country, and there is a great deal of 25-cycle generating apparatus now in use, alternating-current railway motors must be built for that frequency. Dr. Steinmetz expressed the belief that the alternating-current motor would not make any very serious inroads into the field occupied by the direct-current motor. He thought the alternating-current machine will develop a field of its own, just as alternating-current transmission and distribution have supplemented rather than displaced direct-current distribution.

Mr. B. G. Lamme then reviewed the development of the street railway car equipment from the early direct-current systems up to the commutator type of alternating-current motor, and described some of the experimental work which he had done in 1896 with the latter type of machine. He also pointed out that the pure series alternating-current motor is preferable to the repulsion type of motor for the reason that it operates upon either alternating or direct current, while the other is exclusively an alternating-current machine. He then described in detail the method of control used in connection with his series alternating-current motor.

Dr. C. V. Drysdale, of the British Institution, then referred to the Ward Leonard single-phase system, consisting of single-phase motor driving a direct-current generator at constant speed, and direct-current motors taking their supply from the generator, and laid stress on the advantages of this arrangement.

Mr. Frank J. Sprague expressed the opinion that the adoption of electricity on any trunk line will be determined only by financial necessity, and thought that some of the largest expenditures by some railroad companies will be in the purchase and control of competing electric railways. The subject of alternating-current railway motors, he said, he felt unprepared to discuss.

Professor Elihu Thomson referred briefly to his early investigations of the repulsion motor, and a paper was then read by Col. R. E. B. Crompton on "Standardization of Dynamo Electric Machinery and Apparatus." The paper was discussed jointly by Sections B and E of the International Congress on the following day.

THE EXPOSITION SERVICE PLANT.

The steam and electric generating station of the Exposition service plant was designed and installed by Westinghouse, Church, Kerr & Co., and consists of a model plant of 14,000 horse-power capacity, representative of the most recent engineering practice, such as may be found in only a few large cities. The plant includes four 3500-h.p. Westinghouse-Corliss vertical cross-compound reciprocating engines within the Westinghouse enclosure at the west end of Machinery Hall, smaller engines driving exciters in Machinery Hall, engines driving pumps, stokers and cooling tower fans in the service plant section of the Steam, Gas and Fuels Building, just west of Machinery Hall, and Roney mechanical stokers in the latter building. The mechanical draft and cooling tower plants were built from special designs. The auxiliary electric apparatus and switchboard equipment were supplied by the Westinghouse Electric & Manufacturing Company.

The Exposition service plant, although it furnishes the main source of power for the World's greatest fair, and carries all of the commercial operating and lighting load on the grounds and Pike, as well as a large part of the decorative night illumination of the main exhibit buildings, is of interest to engineers, not so much for its size as for its completeness, and because it resembles in general design such big installations as the 40,000-h.p. station of the Metropolitan Street Railway system just completed at Kingsbridge, New York City, or the 75,000-h.p. station of the New York Edison Company.

Boiler Plant.

Steam is furnished by sixteen 400-h.p. Babcock & Wilcox water-tube boilers of the forged header type, set with two boilers in a battery. The tubes and drums are carried by steel frames independent of the brick setting. Two 10-inch loop steam mains, each connecting four batteries of boilers, deliver steam to the two 12-inch mains which carry the steam to the main units in Machinery Hall. Each group of four batteries of boilers is served by an independent induced mechanical draft equipment. Each equipment is provided with two fans, each capable of operating the boilers at their full capacity. A damper, by means of which either fan may be cut in or out of service, is so arranged that, if desired, both fans may be run simultaneously.

The firing of the boiler plant is accomplished by means of Roney mechanical stokers, each group of four stokers in line being driven by a small Westinghouse Standard engine, through suitable gearing. The stoker embodies the principle of the narrow rocking grate, stepped at such an angle as to facilitate a uniform descent of fuel from the coking arch at the top to the dumping gate at the bottom, the coking arch, which embodies the principle of the reverberatory furnace, being highly instrumental in securing perfect combustion of the volatile distillates contained in bituminous coal. On the Exposition grounds the production of smoke is discountenanced, and careful observations of the smoke from the stoker chimneys are made at intervals during the day's run, for purposes of comparative record.

Condensing System.

All main and exciter engines, as well as auxiliaries in Machinery Hall, operate condensing, two complete central condensing equipments being installed, each of 7000 horse-power capacity and serving one-half of the plant. They are of the Worthington elevated jet or "barometric" type, provided with entrainers and rotative "dry air" pumps for removing air from the condenser cones. Both horizontal and vertical types of pumps are in operation, one of the three being held in reserve. In case of loss of vacuum an automatic relief valve allows the exhaust steam from the engine to escape through the roof. A motor-driven valve operated from the floor below by a switch controls the steam inlet to each condenser. Circulating water is supplied to the condensers by a centrifugal pump of the Worthington turbine pattern, direct driven by a Westinghouse compound engine. The hot water discharged into the condenser hot wells is not thrown away, but is cooled for further use in four specially designed cooling towers adjacent to the boiler room. A second turbine circulating pump elevates the hot water into the towers and, in falling, the temperature is reduced by evaporation, which process is further aided by forced draft from the fans located at the base of each tower and driven from the boiler room

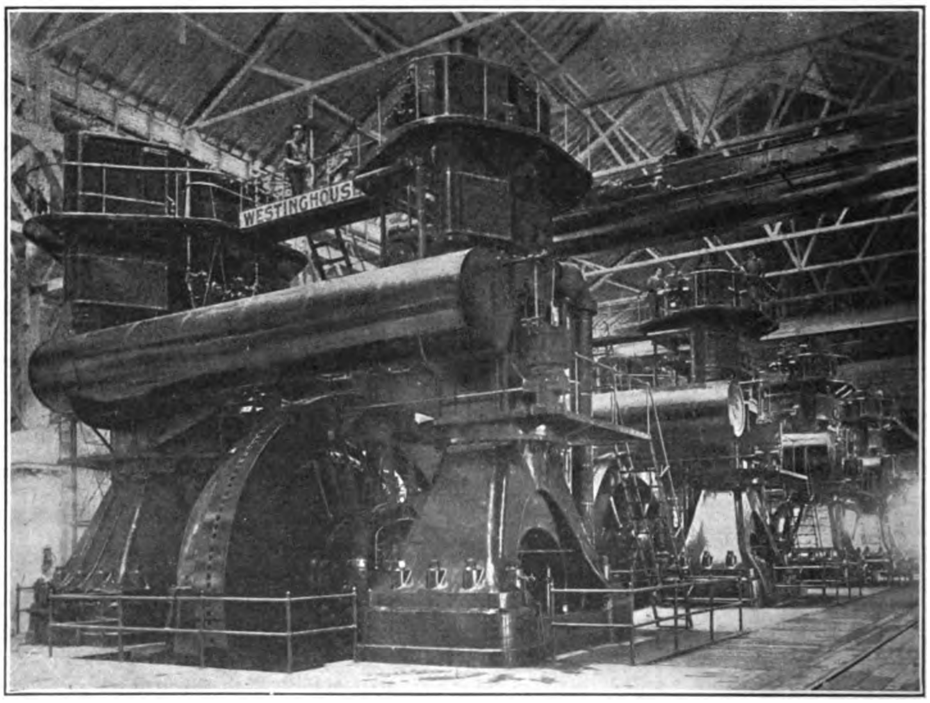

FIG. 1.—VIEW OF MAIN GENERATING UNITS.

by a Westinghouse compound engine. A third turbine pump unit is held in reserve and may be employed on either condensers or cooling towers. Motor-driven valves operated by a switch from the floor control the outlet of each pump.

Steam Piping System.

Two complete systems of steam mains, 12 inches in diameter, convey steam to the main engines. The mains are carried beneath the floor in pipe galleries, anchored firmly to prevent creeping, and supported upon rollers to accommodate expansion and contraction. Entrained water collecting in the boiler room piping is drained out and automatically returned to the boilers by a steam loop and "Holly" gravity return system, which may be seen in continuous operation in the boiler room. A similar system of piping for the boiler room and pumping auxiliaries is connected to the boilers between the drums and main valves, so that steam is always available at the boiler house auxiliaries. These operate non-condensing, exhausting into two Cochrane open feed-water heaters. In the engine room all auxiliaries operate condensing upon the main condensing system.

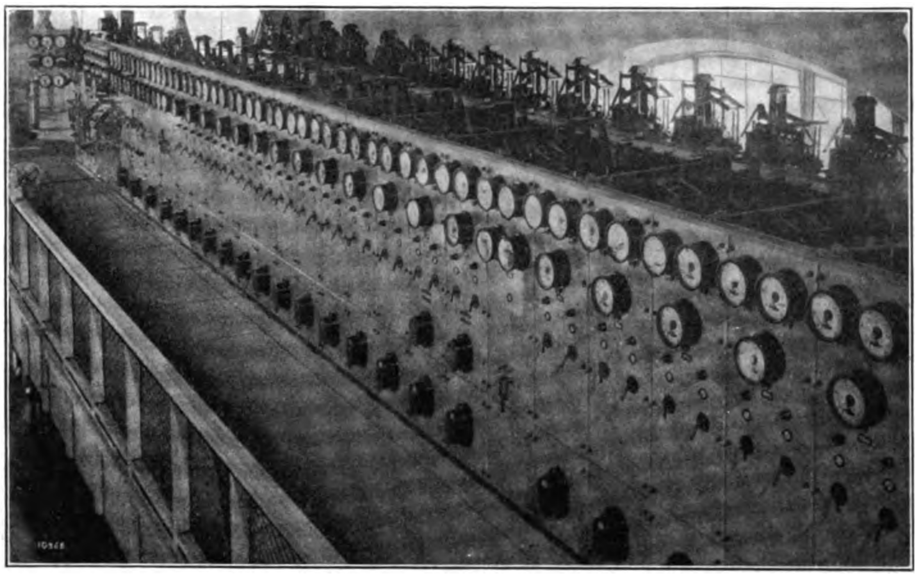

FIG. 2.—VIEW OF MAIN SWITCHBOARD.

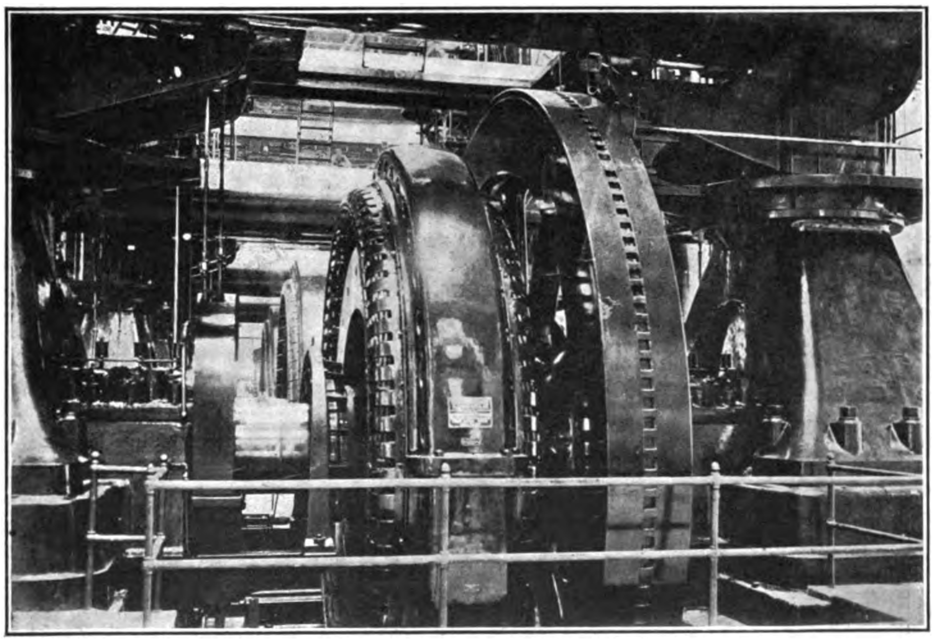

FIG. 3.—NEARER VIEW OF MAIN UNITS, SHOWING GENERATORS.

Generating Units.

The four main units are alike in capacity and general design. The engines are of the vertical "cross-compound" type, and operate at 85 revolutions a minute. As the generator and fly-wheel are mounted between cylinders, a connecting "receiver" is necessary, which is built of riveted boiler steel plate. Bed plates, one on each side, support in order the journals, engine frames, cross-head guides and cylinders. The shaft, which is nearly three feet in diameter at the center, is forged hollow from open hearth steel, fluid compressed to insure perfect homogeneity of metal. On account of the long span the bearings are self-aligning, having spherical instead of cylindrical seats, permitting slight fixture of the shaft due to the load concentrated at the center. Both the bearing shells and the cross-head guides are arranged for water cooling.

Rocking valves of the Corliss type are located directly in the cylinder heads, which connect with "side pipes" paralleling the cylinder walls, a trip release gear on the inlet and a toggle motion on the exhaust controlling these valves. The gear permits a maximum cut-off of three-quarter stroke, enabling each engine to sustain for short periods a load of 5000 horse-power. The speed of the unit is controlled by an enclosed self-oiling centrifugal governor, adjustable while running.

In order to facilitate paralleling the generators, a small motor is provided at the engine, which moves an adjustable weight on the governor mechanism. This motor is controlled from the switchboard, so that the engine speed may be adjusted until the incoming generator has been synchronized and connected to the system. An automatic speed limit is provided on the engines, which instantly closes the throttle should the safe speed be exceeded through breakage of the governor mechanism. This mechanism may be operated also by the engineer from the main floor, by means of an electric switch.

The generators, which are rated at 2000 kilowatts at the usual temperature rise, are of the engine-type revolving-field-magnet construction, with laminated field magnet cores, the armatures strap wound in partially closed slots, and the magnets wound with copper strap on edge. In order to obtain access to the winding the entire generator frame may be moved out of position parallel to the shaft. Three 80-kw. 125-volt Westinghouse engine-type units furnish exciting current for the generator fields.

Electric current from the Exposition service plant and from exhibit power plants in Machinery Hall is transmitted over the network of underground cables at a potential of 6600 volts, transformers being used only at distributing points. All Exposition power is controlled from the twenty-nine panel marble switchboard on the upper gallery over the west end of the main aisle.

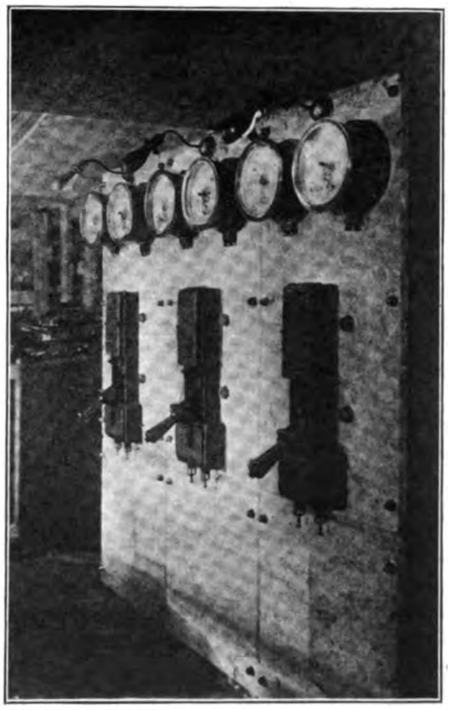

FIG. 4.—SWITCHBOARD IN PUMPING PLANT.

(Fig. 2). The electrically-operated oil switches are behind the operating panels, the bus-bars and instruments on the lower gallery; the bus-bars in duplicate and housed in a structure of masonry with intermediate barriers. All main generator and feeder switches are installed in independent fireproof vaults, and are electrically operated from the main panel, indicators showing whether a switch is open or closed. Remote or relay control of high-tension current is exclusively employed. The switchboard is supplied with Westinghouse and General Electric instruments and control apparatus.

In the design of the service plant, no important feature of a modern central station was omitted. The Niles electric traveling crane over the main engine units in Machinery Hall is of 40 tons carrying capacity and bridges a span of 80 feet. It is equipped with three Westinghouse motors: one of 20 horse-power capacity, to drive the bridge, located at about the center of the girder, and two, one of 20 horse-power capacity for hoisting and one of 5 horse-power for moving the trolley, being mounted on the trolley itself. The motors are controlled from the crane cab, of course. Current at 110 volts is supplied to them by the exciters for the main engine units.

Summary of Dimensions, Rating, Etc.

Main Engines:

Diameter of high-pressure cylinder, 38 inches.

Diameter of low-pressure cylinder, 76 inches.

Stroke, 54 inches.

Shaft, 31 inches diameter and 25 feet in length. Fluid compressed open hearth steel. Weight, 50,600 pounds.

Speed, 85 revolutions per minute.

Boiler pressure, 150 pounds.

Vacuum, 26 inches.

Cranks, counter-balanced disc, 90 degrees angularity.

Fly-wheel, 23 feet diameter. Weight, 170,000 pounds.

Fly-wheel effect, 13,110,000 pounds.

Weight of engine, without fly-wheel, 576,000 pounds.

Weight of engine, with fly-wheel, 746,000 pounds.

Generators:

2000 kilowatts each, revolving field, engine-type, three-phase; voltage, 6600.

Frequency, 25 cycles per second.

Overload capacity, 50 per cent. for one hour.

Total weight, complete, 196,000 pounds each.

Exciter Units:

Three 6-pole 125-volt generators, of 80 kilowatts each, direct-connected to three 12-inch and 20-inch by 12-inch Westinghouse compound engines; 300 revolutions per minute; operating condensing.

Barometric Condensers:

40-inch Worthington elevated jet or barometric type, supplied with injection water by a 30-inch main from circulating pumps. Overflow from hot wells returned to circulating pumps by wood conduit. Main valves operated from floor by electric motors.

Dry Air Pumps:

One Worthington vertical, single-stage, rotative type. Steam cylinder, 8 inches x 12 inches. Air cylinder, 16 inches x 12 inches.

Two Worthington, horizontal, single-stage, rotative type. Steam cylinder, 10 inches diameter; air cylinder, 22 inches diameter; 18 inches stroke. Pumps operate condensing.

Boilers:

Babcock & Wilcox water-tube type, inclined forged steel header. Rated capacity, 400 horse-power each; 6400 horse-power total.

Centrifugal Circulating Pumps:

Three Worthington, direct driven, turbine type, 24-inch discharge. Capacity of each, 17,000 gallons per minute under a 50-foot total head. Each pump driven by a Westinghouse single-acting, compound engine, 18 inches and 30 inches x 16 inches. Governor arranged to vary speed according to pump output.

Boiler Feed Pumps:

One Worthington vertical duplex "Admirality" type. Steam cylinder, 14 inches diameter; water cylinder, 10 inches diameter; stroke, 18 inches.

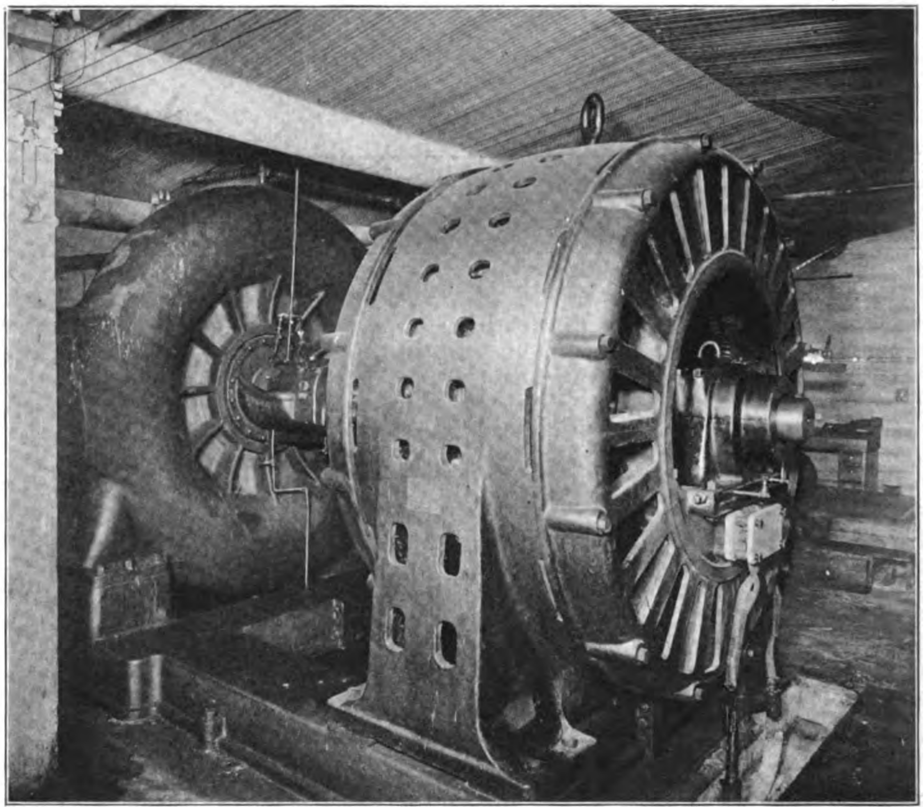

FIG. 5.—2,000-H.P. INDUCTION-MOTOR PUMPING UNIT.

Two Worthington horizontal, compound, duplex, outside packed plunger type. Steam cylinders, 9 and 16 inches in diameter; water plungers, 7½ inches diameter; stroke, 15 inches.

Forced Draft Cooling Towers:

Effective area of each tower, 460 square feet; each equipped with four 120-inch Seymour disc fans. "Make-up" water, replacing the amount evaporated, is supplied from city mains.

The Cascades Pumping Plant.

The Cascades, which are so beautiful and attractive a feature of the Exposition, are supplied with water by three large Worthington centrifugal pumps. The induction motors by which they are driven are said to be the largest in the world. They are rated at 2000 horse-power each and were built by the Westinghouse Company. The design is substantially the well-known "Type F" motor of that company for variable speed service. The stators are wound three-phase for 6000 volts and 25 cycles, and run at 365 r.p.m. The rotor windings are made up of coils of copper strap arranged three-phase and connected through collector rings of the spider type to grid resistances varied by a hand controller with 34 steps. Each pump is capable of delivering between 35,000 and 40,000 gallons of water per minute. At the present time the Cascades are in operation five hours each day. One pumping unit has been found sufficient to supply all the water needed.

The motors are controlled from a three-panel switchboard located in the pumping station, one panel being arranged to handle each motor. The board is equipped with Westinghouse ammeters, voltmeters and automatic circuit-breakers. The circuit-breakers and motor controllers are interlocked so that it is impossible for an attendant to close a main switch unless all the motor resistance is in circuit.

The pump motors are started very gradually at the advertised hours throughout the day and evening, the current being slowly raised to normal by means of starting rheostats under Festival Hall, which, because of the exceptionally large size of the motors, have many steps. Integrating and indicating wattmeters at the ends of the cables in Machinery Hall record the motor load when the Cascades are in operation.

The pumping station is located under the extreme left of the Cascades and is well worth a visit by engineers who are interested in operations of this kind.

Abstracts from Foreign Contemporaries

Holmes-Page Automatic Starting Switch.—The London *Electrician* in an article describing the electrical equipment of the press room of the London *Graphic* gives a description also of the Holmes-Page regulating switch shown by Figs. 1 and 2 herewith, which has been designed especially for those cases in which a motor is started and stopped frequently as in the "making ready" process of printing. The starter comprises a double-pole switch with no-volt and over-load release working in conjunction with a slow motion rheostat with a dashpot control, so that the resistances cannot be switched out too rapidly however quickly the lever may be turned. When the operating handle is moved from the "off" to the "on" position, a double cam which it carries engages with a projection on the double-pole switch arm and closes the switch, an iron armature carried by the switch arm being brought up against the faces of the hold-on bobbin at the same time. When the operating lever is moved on a little further, the double cam is released, but the double-pole switch is left closed by the action of the hold-on bobbin. When this slight further movement is given to the operating lever, the rheostat arm is set in motion in the direction to cut out resistance, but the rate at which it does this is controlled by the dash-pot already referred to, and may be adjusted to suit any particular conditions. When it is desired to stop the motor, the handle is moved to the "off" position, which first opens the double-pole switch and then rapidly inserts all the starting resistance ready for starting up again. Should the double-pole switch open, in consequence of the failure of the supply or through the action of the overload device, it is impossible to close the double-pole switch again without first inserting all the resistance.

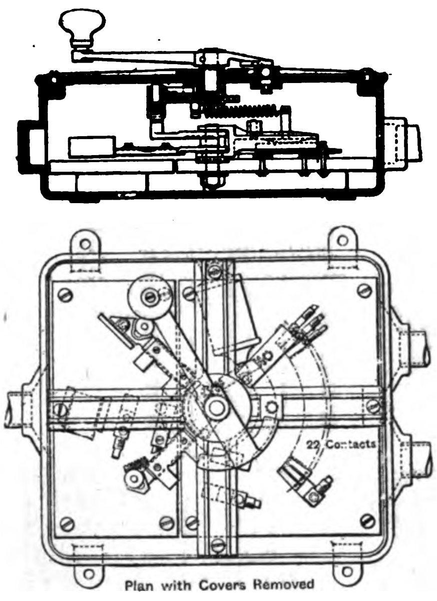

FIG. 1.—AUTOMATIC STARTING SWITCH.

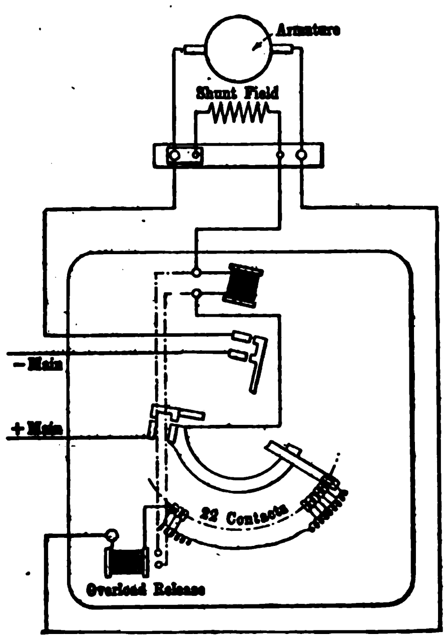

FIG. 2.—DIAGRAM OF CONNECTIONS.

Gas Engine Starter.—The accompanying sketch, taken from the London *Engineer*, shows what is called by its makers the "Perfect" starting apparatus for gas and oil engines. The construction is simple, the only internal working part being a steel ball valve. To start the engine, the crank is placed in such a position that all the valves are closed; the screw plug on the top of the starter is then removed, and the ball pressed down with a prober, which is supplied with the starter. The required quantity of gasoline is then poured into the funnel-shaped reservoir, and by it passed through the projecting pipe into the cylinder end. The funnel pipe is then twisted out of the way. The fly-wheel is then moved a little forward in order to draw in the requisite amount of air through the starter. By bringing the crank nearly back to its original position, compression is obtained and the ball is forced back on to its seating. The prober is again used to press down the ball until its falls by its own weight, then by placing a lighted match over the hole in the starter the engine is started without further manipulation. The screw-plug is then replaced. The quantity of benzine required is small, being, it is said, about a thimbleful to start a 50-horse-power engine and about half this quantity for a 10-horse-power engine.

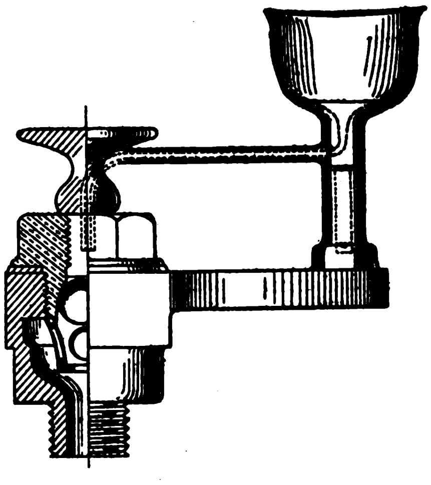

FIG. 3.—GAS ENGINE STARTER.

An Insulator for Conductor Rails.—Among the many problems attending the substitution of electric power for steam locomotives in railway working, of no small importance is the attainment of a thoroughly satisfactory means of supporting and insulating the conductor rails. It is essential that the rail supports, while providing permanent insulation under the difficult conditions prevailing on railway tracks, should be substantial enough to withstand rough usage and sufficiently strong mechanically to resist considerable vibration and shock. The London *Electrical Review* describes the newly patented insulator shown by Fig. 4 in a recent issue. This has been designed with a view to meeting the above requirements. It consists of a pedestal of porcelain of substantial proportions with a large base resting directly upon the rail tie and secured thereto by external malleable iron fastenings. In this respect it differs considerably from earlier types of rail insulators in which the porcelain is supported on a central stud after the manner of telegraph insulators. The conductor rail is held in position by a chair of malleable iron, provided with a depending stud which is cemented into a recess in the insulator. The insulator shown in the illustration is fitted with a chair for a conductor rail of rectangular section. The same type is supplied with chairs adapted for other sections of rail—*e. g.*, flanged or channel sections. The insulator is of high-grade vitreous porcelain of a form well adapted for manufacture, and it will be seen from the illustration that it occupies the whole of the vertical space below the rail, thus presenting a maximum length of path to resist surface leakage of current.

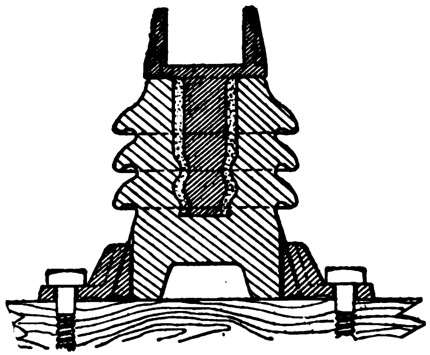

FIG. 4.—THIRD RAIL INSULATOR.

The Testing of Transformer Oil.—The usefulness of an oil as an insulation material is not determined by measurements of its insulation resistance, says the London *Electrical Engineer* in an abstract from the *Zeitschrift für Elektrotechnik*, but by measurements of the voltage required to break down a given thickness. A pair of polished balls should be supported at a fixed distance below the surface in a vessel containing about 200 cubic centimetres, and having a diameter about 3 cm. The presence of water or air bubbles or small fibres greatly affects the results obtained. For the purpose of determining the flashing point of the oil, a weighed quantity of it should be heated for about 12 hours in a water bath at 100° C., and the amount evaporated noted. The point at which steaming commences should be as high as possible, as the flashing point occurs at about the same temperature. The effect of water is so important that the presence of only .06 of 1 per cent reduces the breakdown voltage by half. Further additions of water have little effect. The presence of water may be qualitatively determined by adding a little cupric sulphate to the oil. When free from water this sulphate is pure white, but becomes blue when in contact with water. A good transformer oil may be distinguished by the following properties: (1) It should be a pure mineral oil obtained from crude petroleum by frictional distillation without chemical treatment; (2) the flash-point should not be below 180° C., and the oil should not burn steadily under 200° C.; (3) the oil should be free from alkalies, moisture, or acids; (4) after being heated for eight hours the evaporation should not exceed .2 of 1 per cent; (5) the oil should be as fluid as possible, and should have a light-yellow color.

Lister Two-Cycle Gas Engine.—The Otto cycle, which has practically displaced all other cycles of operation in gas and oil engines, has the great drawback that the piston receives only one impulse during every two complete revolutions of the crank-shaft; hence, not only is close governing rendered difficult, but the engine has to be of excessive size and weight for a given power. Many designs have been suggested from time to time by which the number of impulses per revolution could be increased, the latest which appears in London *Engineering* being an application of the "triangular connecting-rod" motion, originally introduced for the purpose of reducing the number of cranks necessary in a triple or quadruple-expansion steam engine. A two-cycle internal-combustion motor built on this principle is shown by Figs. 5, 6 and 7, which show the internal arrangements. It will be seen that two cylinders, *A* and *B*, are arranged parallel to each other above the crank-shaft, *A* being the exhaust and *B* the inlet cylinder, connected by a common compression chamber at their inner ends. The pistons are joined by the connecting-rods R^1 and R^2 to two corners of the triangular frame, as shown, the other corner being attached to the crank-pin, *C*. The movement of the frame is constrained by the radius-rod, *L*, the other end of which is jointed to the casing of the engine. Ignition of the compressed charge takes place when the pistons are in the position shown by Fig. 6. The crank rotates in the direction of the arrow, so that piston *B* travels faster than piston *A*, and has approached the end of its outstroke by the time the latter piston has arrived at the exhaust-port. Their positions are then as in Fig. 7. When the exhaust-port is uncovered, the pressure drops to atmospheric, and piston *B*, then passing an inlet port communicating with the enclosed crank-chamber, allows a volume of air to pass through the check-valve into the cylinder *B* in order to scavenge the cylinders from the products of the previous explosion. The piston *B* then commences its stroke again in advance of piston *A*, forcing out a quantity of air, and nearing the end of its instroke at the time the exhaust-port is closed by piston *A*. The position of the pistons before compression is shown in Fig. 5. Shortly before the closing of the exhaust-port a charge of gas or oil is pumped into the cylinder *B*, forming an explosive mixture with the air previously drawn in. In engines, the close governing of which is not essential, the charge may be drawn into the crank-chamber with the air, and thence delivered to the cylinder, thus doing away with the necessity for pump-charging, though the advantages of scavenging are lost by this arrangement. The mixture is compressed as the pistons approach the upper end of the cylinders, ignition is effected by any of the usual methods, and the cycle is repeated as before, one explosion taking place to every revolution of the crank-shaft. It will be noticed that the initial volume of the charge is increased by from 50 to 70 per cent before the exhaust, allowing more work to be obtained from the fuel together with a lower exhaust pressure. The ratio of expansion volume to compression volume is 6.8. The design permits of the connecting-rods being kept very short, and they are so proportioned that at no point of the stroke do they make a greater angle with the centre line of the cylinders than 5 deg., thus the pressure on the cylinder walls and consequent wear is very small. The combined effective power strokes of the two pistons are approximately equal to 1.8 times the crank stroke, the compression portion of the return stroke amounting to 1.2 times the crank stroke.

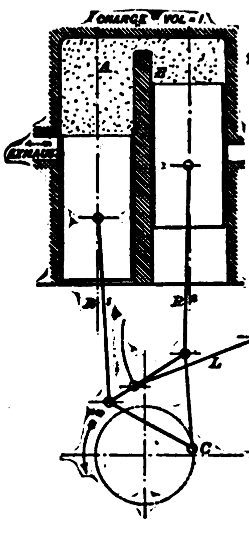

FIG. 5.

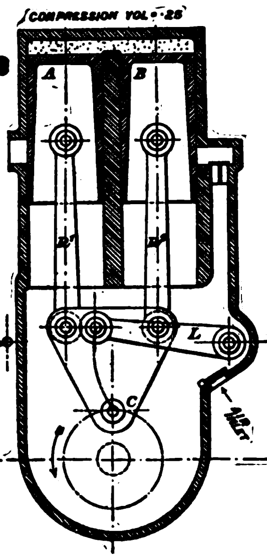

FIG. 6.

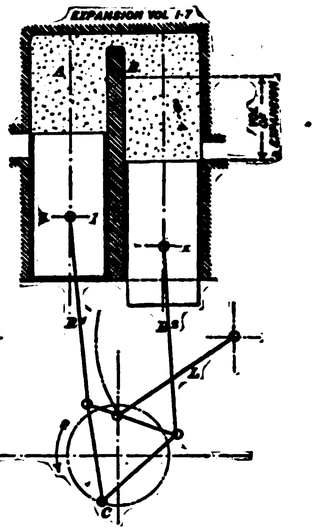

FIG. 7.

Some Notes on Testing.—"C. H. R. T.," in a recent issue of the London *Electrical Engineer*, claims that while many articles dealing with shop testing have been written, there are a few convenient and simple tests which are always carried out but seldom mentioned. When a motor is to be tested for speed it may happen that there is at hand no supply of the proper electromotive force. It may also happen that when a dynamo is to be tested for voltage there is no convenient method of driving it at the proper speed. In the latter case the dynamo may be run as a motor, should there be a suitable supply of power; but should the voltage be too low, the speed of the dynamo or the motor will also be low, and a correction must be made. The correct speed of the dynamo or motor operated in this way will be found from the following formula:

$$DS \div MS = (DV + LV) \div (MV - LV)$$

where DS is the speed of the machine running as a dynamo; MS the speed at which it will run as a motor on its proper voltage; DV the voltage generated as a dynamo; MV the voltage for which the machine is designed; LV the volts lost in the armature and series field coils, if any. It is more convenient to test the speed of a motor by driving it as a dynamo, but the speed is not exactly right. The same formula will give the speed at which the machine will run upon the proper voltage. Before sending out a compound dynamo or motor, it is desirable that it should be tested to see if all connections have been made properly. The convenient way of doing this is to short-circuit the series winding for a few seconds after the machine has been put in operation. In the case of a dynamo the external current will increase if the series winding opposes the shunt. It will decrease if the machine is correctly coupled. In the case of a motor, the external current of the driven machine will decrease if the machine is wrongly coupled and increase if it is correct. For these tests the most convenient have supply mains of fairly low voltage—say about 100—in a convenient place, so that all machines above that voltage may run on them. In making this test care must be taken when a high-voltage shunt machine is connected to the low-voltage circuit. When this is done it is frequently necessary to start the machine by hand, owing to the weak field.

Notes on Steampipe Work.—An interesting article on this subject by M. Westphal appeared in a recent issue of a German contemporary. With regard to material for steam pipes, the author considers that above eight atmospheres and 200° C. copper and bronze should not be used. For higher values mild steel may be used. Referring to drainage, he states that every right-angled bend offers an opportunity for getting rid of water, by employing a blanked tee-piece and trapping the blanked leg. Frequent drainage is essential, and danger of water-hammer can occur if a valve is quickly opened. It is a mistake to suppose that no water accumulates if superheated steam is used. As a matter of fact, with big pipes the steam in the upper part of a horizontal pipe can remain superheated, while there is an accumulation of water at the bottom, and this puts severe buckling strains on the pipes, which should, therefore, be as frequently drained as for saturated steam. He does not regard the centrifugal separator as very satisfactory, and prefers a box with steam entering vertically and leaving horizontally. In order to compensate for expansion the material may in some cases be anchored at one or more places and the run of the pipes arranged so that expansion can safely take place. Where double right-angled bends occur, every use should be made of twisting flanged joints, which may be of special construction, or even ordinary flanges with the holes enlarged. Another form of joint which can sometimes be made use of is the spherical. Long vertical lengths of pipes may be hung from the ends of counterbalanced levers, thus allowing for expansion while affording a good support. If the diameter of pipe is too large, the heat loss of water deposited is great, and may even cause a drop in pressure; if too small, severe vibrations may be set up in the pipes, but no standard figure for velocity is given. He suggests that it is best to work with rather small pipes and keep the boiler pressure somewhat excess of the working pressure at the engine valves. The author considers that the steam separator in front of the engine should be much bigger than it usually is in order to feed the engine more evenly and keep down vibration. Face joints are recommended, or joints with flat metal rings let into one flange.

Testing of Alternating-Current Motors by Direct Current.—In a paper read recently before the British Association, at Cambridge, W. Cramp gives some notes regarding the testing of alternating-current motors by direct current. Since an alternating magnetic field may be resolved into two equal rotating fields, each of 0.7 times the value of the original field, it follows that there is a close connection between the behavior of an alternating-current motor on its normal supply and that of the same motor having the stator supplied with a direct current of the proper value, while the rotor is driven round at the proper speed by some independent means. As an example of this he cites a repulsion motor. On account of the fact that such motors will usually be arranged for constant-pressure circuits, it follows that the total flux vibrating within the primary coils is practically constant. This means that the rotating fields, which take the place of this vibrating field, are also practically constant in magnitude for any given brush position. Thus the behavior of the motor becomes similar to that of a single-phase alternator upon varying load, and consequently obeys the same laws. These laws form a variant upon the circle diagram so well known as illustrating the behavior of polyphase motors. The motor, then, may be treated as if it were a short-circuited single-phase alternator, and the more important tests may be carried out as follows: I.—Arrange the motor so that its stator may be excited with a direct current, equal to $1.41 A \cos 2 d$ amperes (where A is the normal magnetizing current of the motor, d the angle between the brush line and the polar axis), and so that the rotor may be driven by a direct-current motor. II.—Calibrate the direct-current motor so that the power required to drive it at any particular speed is known. III.—Connect it to the alternating-current motor shaft (the alternating-current motor not being excited), and measure the power required at various speeds. (Friction and windage.) IV.—Drive as above (in II.), but with the rotor on open circuit, and stator excited with direct current as explained above. (Rotor hysteresis and eddy losses, hence, also, stator hysteresis and eddy loss.) V.—Close the rotor circuit by connections which revolve with the rotor, and excite (as in III.), and run at what would be synchronous speed. This gives the rotor current at standstill (if desired, for various values of d). It also gives, if the speed is varied, the rotor power-factor at standstill—a most important point. VI.—With the same direct current the resistance of rotor and stator may be measured. Thus all the losses of the motor are completely known, as well as the rotor current and power-factor, and the performance of the motor may be predicted exactly. The method enables a very satisfactory test to be made, when alternating current of the right voltage and frequency is not available, which is an important point, especially in England, where the frequencies are so varied as to make it necessary to have a great deal of apparatus to test even a moderate run of motors. No wattmeter is necessary, which is another advantage.

Some Recent Electrical Patents

Interlocking Electromagnets.—There are many applications of electromagnets in which it is desirable that when one of a group of magnets is actuated all of the others shall be restrained from operation, accidental or otherwise, until the first magnet has been restored to its idle condition. A favorite means of accomplishing this is to cause the magnet first operated to open the exciting circuits of the others. Mr. William Baxter, Jr., however, prefers to bar the action of the remaining magnets mechanically, as indicated in his patent drawing, Fig. 1. The arrangement consists of a locking bar, 50, slidable horizontally and normally held at the right-hand limit of its travel (as the drawing is made) by a weight, 64, and bell-crank lever. The solenoid extensions carry each a pin, 16, which projects into an L-shaped slot in the locking bar. Should one of the solenoids be excited, the rising of its plunger will force the bar over to the left by the action of the pin in the slanting part of the slot; this obviously will lock the other plungers, their pins being then in the horizontal part of the slots. The inventor does not mention the fact that in order to operate a locking mechanism of this kind each solenoid must be very much longer than would be necessary merely to lift the circuit-closing contracts—probably three or four times as long. Patent No. 766,865.

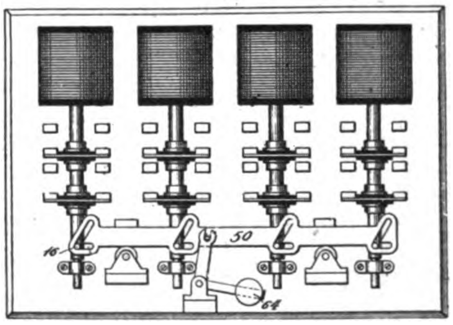

FIG. 1.—INTERLOCKING ELECTROMAGNETS.

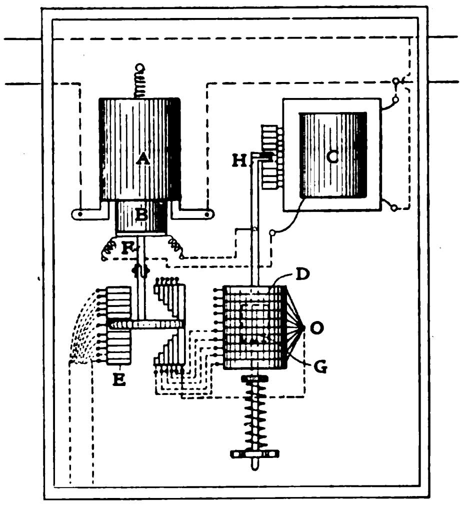
Regulator for Alternating-Current Circuits.—The essential requisites for an automatic regulator for alternating-current circuits are: (1) That it shall be susceptible not only to voltage variations, but also to current phase variations; (2) That it shall consume but little energy itself; (3) that it shall be sensitive and dead beat, that is to say, it must not be affected adversely by the change it causes; (4) the action of the regulator should be as little as possible periodic, to prevent unnecessary fluctuations in the line and increased self-induction. A regulator intended to meet these requirements has recently been patented by Ludwig Gutmann, of Peoria, Ill. Fig. 2 shows diagrammatically one of the types covered by the patent. The apparatus is essentially a switchboard device consisting of a main circuit solenoid coil, A; a potential solenoid coil, B, connected across the terminals of a variable ratio transformer, C; a controlling solenoid, D, and contact terminals, E, connected by means of a cable to the exciter of the alternator. It is evident that the pull exerted by coil A on coil B will vary with the pressure across the terminals of coil *B* and also with the power factor of the circuit. The transformer, *C*, with its primary connected to the line, delivers a secondary e.m.f., which varies, of course, in accordance with variations in the line e.m.f. The secondary winding is subdivided and provided with contact terminals to allow adjustment of the ratio of transformation. The solenoid, *D*, consists of a number of superimposed coils having one terminal in common and the others arranged so that the contact arm, *F*, attached to the coil *B* may place them successively in parallel with one another. The core *G* of the solenoid *D* is provided with a contact arm, *H*, which is in sliding connection with the terminals of the subdivided secondary of the transformer *C*, precautions being taken to prevent short-circuiting at successive secondary terminals. Finally, the contact arm *F* is simultaneously in circuit with the terminals *E* of the cable, as well as with those of the coil *D*, the number of contacts being the same in both cases.

The exciter is provided with an ordinary shunt field-magnet winding and also with a subdivided series winding, which subdivisions are connected to the cable ending at the terminals *E*, Fig. 2. The positive brush, the common terminal of the sectional or subdivided series winding and that of the solenoid *D* are all connected together at *O*. The normal conditions for non-inductive load are as shown in Fig. 2, the shunt winding acting alone, no series turns being included, and the solenoid *D* being without any excitation. Now if, because of change in load or phase displacement, the potential drops, then the solenoid *B* will descend, shifting its contact both with *D* and *E*. The consequence is that additional ampere-turns are added to the field of the exciter, causing its e.m.f. to rise and to send a greater current to the field of the alternator, raising the e.m.f of the latter to normal. The effect of the changed position of *F* on the solenoid *D* is that one or more coils receive current from the exciter and pull down the core, *G*, which shifts the contact *H* and thereby reduces the transformer ratio until the secondary e.m.f. is raised to that which caused the regulator to act. Although its excitation is now raised again to normal, the solenoid *B* will not shift its position because its terminal e.m.f. is the same as when the regulator began to act; and as long as the additional excitation is required the solenoid *D* will hold the contact *H* in the fixed position. This feature of reaching stability, after correcting the voltage, is desirable in circuits where many motors are frequently started and stopped, as in a power distribution system operated by alternating currents.



Am. Elec.

FIG. 2.—ALTERNATING CURRENT CIRCUIT REGULATOR.

If circuit conditions alter and the power factor of the circuit increases, for example, the mutual pull between coil *A* and coil *B* increases and the latter is drawn up. This reduces the field excitation of the exciter and simultaneously reduces the pull of the solenoid *D*, thereby lowering the transformer ratio to compensate for the reduction in line e.m.f. The device is capable also of compensating for leading currents in a similar way, the difference being that in such a case the series turns cause a demagnetization of the exciter field, and the solenoid *D* makes contact with secondary terminals giving transformer ratios greater than normal. The regulator may evidently be adapted for polyphase circuits and the actuating solenoid may be substituted by a suitable motor or rotary converter of, say, ¼ horsepower capacity. Obviously, also, instead of using a special form of exciter the field variations of the alternator may be obtained with any standard exciter and a variable resistance included in series with the alternator field winding or the exciter shunt winding. In connection with large machines the same regulator may be used by shunting a part of the total main line current for the purpose of energizing the coil *A*. Moreover, if an alternator and exciter provided with this regulator be placed in a circuit subject to wattless currents and the alternator be operated with over-excited fields as a synchronous motor, it can be made to compensate for phase variation and maintain a fixed power factor by having its field excitation adjusted automatically. Patent No. 769,342.

Hydraulic and Electric Elevators.

To the Editor, American Electrician:

In your editorial on "The Passenger Elevator" in the September number too much stress has been placed on the disadvantages of the hydraulic elevator, while you have utterly ignored the important disadvantages of the electric elevators. The writer agrees with you that "each system has its legitimate field of operation in which it is distinctively superior to its rival." But when comparisons are made the disadvantages as well as the advantages of both types should be clearly set forth in each case, and discussion should be limited to the types in universal use.

Three advantages for the hydraulic elevator have been cited in the editorial, but the most important one of all was omitted. The fact that the hydraulic elevator car cannot by any possibility run into the top or bottom of the hoistway, provided proper hoistway clearance is given, is assurance of safety, and should be given first consideration.

The hydraulic cylinder should be in length properly proportioned to the rise of the car, so that the piston automatically cuts off the ports and acts as a valve cushioning on water, which may be against the cylinder head.

The "positive limit" has been wrongly ridiculed in the editorial, as all engineers, familiar with detail construction of both types of elevators, will agree; and that advantage is conceded to be the first and most important advantage of the hydraulic elevator. One seldom reads of an accident due to a hydraulic elevator driving its car into the overhead work and pulling the hoisting ropes out of their sockets, as in the case of many accidents with the electric machine.

As to the disadvantages, one cannot emphasize the serious inefficiency of the hydraulic elevator too much, but the second and third disadvantages cited in the editorial are unimportant, depending entirely upon the type of elevator, class of service, and the building in which the elevator is to be installed. In many cases hydraulic elevator machinery will fit in where it would be impossible to install an electric machine.

Of the two types the electric elevator is the most economical, because it is convenient to overbalance the car. The counterbalance is made to balance the car with its average load, in which case the elevator has no gravity work to perform. A serious disadvantage, which was utterly ignored in the editorial, is the lack of absolute means of stopping its hoisting power when the car or counter-balance arrives at the top of the hoistway. The failure of automatic limit devices has caused more accidents than all the other parts of the machinery put together. It is safe to say that four out of five accidents have as primary cause the failure of the automatic limits to properly shut off the power. There is not a drum elevator to which the hoisting and counterbalance ropes are shackled that is not liable to run its car or counter-balance into the top of hoistway and cause accident.

Automatic devices are operated by both the car and the hosting machine to shut off the power and apply the brake at the limits of the car's travel, but they are adjustable, removable and breakable, and nothing but constant care and attention on the part of the engineer in charge can assure their proper action. It is on account of this serious disadvantage, which stands out prominently in proportion to the speed of the car, that hydraulic elevators have been almost universally adopted for office building use, where high speeds and heavy loads are involved.

However, there are two forms of electric elevators that are not hampered with this disadvantage, namely, the Sprague-Pratt screw machine and the friction-drive cable drum type. The Sprague-Pratt screw machine compares favorably with the hydraulic in safety combined with high speeds, because they both have in common the characteristic of positively limiting the car travel and the impossibility of dangerous speed acceleration. With the cable-drum, friction-drive type, and some of the modern forms of traction elevators, although having an elastic operating medium, the car can go into bumpers at full speed without injury or discomfort to the passengers. However, special air bumpers for both car and counter-weight are necessary whereby the landing of either the car or the counter-weight on the buffers slacks the traction cable, and positively arrests the hoisting effort. The driving drums can then keep on revolving indefinitely, and no injury or danger be incurred. This same function also prevents the paying out of slack cable when the car is stopped in its descent by the car safety or other causes other than the hoisting machine.

Summing up tersely: Hydraulic elevators are safe and reliable, but inefficient; especially adapted to office building service.

Electric elevators are efficient, and especially adapted to stores, hotels and all moderate-speed service (with the exceptions here noted).

New York. EDW. VAN WINKLE.

The warmth of Mr. van Winkle's admiration for the hydraulic elevator seems to have impaired his consistency and distorted his interpretation of our remarks last month. After saying that we omitted the "most important advantage" of the hydraulic elevator he states that we "wrongly ridiculed it." We beg to differ with him on both points. We also beg to remind him that possibilities are not necessarily realized facts; no one will deny that the hydraulic elevator has greater possibilities in the way of positive travel limits than the drum electric type, but everyone conversant with the subject knows that there are many installations in which the positive limit to the piston travel does *not* insure positive limit to the car travel short of the bumpers or overhead work. We have conceded that the control apparatus is much more rugged and reliable in hydraulic than in electric elevators and that the former has the great advantage of a non-elastic operating medium, requiring no brake, while the electric system has not; these features are responsible for the fact that fewer hydraulic than electric cars are dragged into the overhead work or run down to the bumpers at full speed, and not the much-vaunted "positive limit."

While admitting the absence of an inherent positive travel limit in the drum electric system, we may say that we have several times noticed installations of this type in which the limit safeties were so thoroughly reliable as to be practically equivalent to a positive travel limit. No one, we think, will dispute that it is only a matter of good engineering to provide a limit device which will make it impossible for the motor to continue running after the car has passed the upper or lower limit.

There is not much gain, however, in arguing on the basis of what might be done under ideal conditions with either system; our editorial remarks were incited by our observation of what is actually done in practice, and we still see no reason to put the positive travel limit of the hydraulic piston at the head of the list of advantages of that system.

As to the relative space advantages of the two systems, we cannot quite appreciate the unimportance ascribed to this feature by our correspondent. We happen to know of cases in which the rental income from the space saved by the use of electric elevators paid for the entire equipment in a few years.

Mr. van Winkle's remarks concerning the Sprague-Pratt screw elevator are not especially relevant in view of the obsolescence of the system.—[EDITOR.]

The Adoption of 220-Volt Incandescent Lamps at St. Louis in 1899.

To the Editor, American Electrician.

SIR:—In a paper I read before the National Electric Light Association, at Boston, in May, reference was made to the use of the 220-volt lamp in St. Louis. I made the statement that the installation at St. Louis in 1899 was made under the engineering advice of Mr. Bion J. Arnold. Mr. H. H. Humphrey, of St. Louis, advises me that the recommendations covering the adoption of the 220-volt lamp in the installation in question were made by Messrs. Bryan & Humphrey, in September, 1897, and that the system was installed under their direction as supervising engineers. In view of these facts I would be pleased to have you publish this correction.

WALTER I. BARNES.

Providence, R. I.

NOTES.

International Electrical Exposition.—An international exposition will be held, under the auspices of the Electrical Contractors' Association of New York City, at Madison Square Garden, December 19-28, 1904. The executive committee is composed of Joseph R. Strong, chairman; E. S. Keefer, E. K. Comstock, J. P. Hall, J. C. Hatzel, S. Davis and G. W. Russell, Jr. The managing directors are Messrs Weber and Rush, and the business representative is Mr. M. Spiegel, Madison Square Garden, New York City. It is the intention to make this exposition exclusively an electrical industrial exhibit. Applications for special privileges must be submitted to the managers not later than December 10, 1904.

The Dangers of Gas Stoves.—In a paper read recently before the Engineers' Society of Western Pennsylvania, Mr. Francis C. Phillips discusses the domestic gas stove from a sanitary standpoint and brings out some points that should be of use to advocates of electric heating (within rational limitations). He advocates placing the installation and use of gas stoves under the supervision of the health authorities in all municipalities. In support of this contention he points out that coroner's juries in Allegheny County, Pennsylvania, who have rendered verdicts in cases of fatal poisoning caused by the improper use of gas stoves, have frequently coupled their verdicts with recommendations that a law be enacted forbidding the use of gas stoves without chimney connections. He further states that as modern houses are built, there are usually to be found in every dwelling several rooms without chimney flues, and as heating by gas stoves affords frequently the only practicable method of rendering such rooms habitable, the enactment of such laws would necessitate the further enactment that every room shall have a chimney flue. Gas stoves offered for sale should be subjected to tests and if found to yield carbon monoxide or formaldehyde when used with gas under varying conditions of pressure, should be condemned. That a gas stove can be used without danger of production of the poisonous substances resulting from incomplete combustion should be attested by an official certificate, and without such a certificate its sale should be illegal. The manner of using a gas stove in a dwelling house should be as much a matter of official inspection as the plumbing. Carbon monoxide is the most poisonous gas to which the dwellers in city houses are ordinarily exposed, and its effects are without doubt being unknowingly felt by many as the result of faulty construction and improper use of gas stoves.

Recent British Power Plant Failures.—The annual report of the British Engine, Boiler and Employers' Liability Insurance Company, contains, as in previous years, many valuable deductions. The majority of casualties is due to ignorance. Failures in steam and gas engines are classified thus:

	Steam engines. Per cent.	Gas engines. Per cent.
Due to accidents or causes unascertained	31	29
Negligence of owner or attendants.	18	32
Old defects or wear	30	14
Weakness, bad design, or workmanship	21	25
	100	100

In electrical machinery the failures are classified as follows:

	Dynamos. Per cent.	Motors. Per cent.
Armatures or rotors	62	50.5
Magnets or stators	12.5	11.5
Commutators or brush gear	17	14.5
Miscellaneous	8.5	8.5
Switch gear	...	15
	100	100

and causes of failures are stated to have been due to:

	Dynamos. Per cent.	Motors. Per cent.
Accident	14	12
Dirt and oil	10	15.5
Age and deterioration	24	19.5
Bad workmanship or design	17.5	18
Overloading	3.5	5.5
Not ascertained	31	29.5
	100	100

The Neuchatel Station.

In the description of the central station plant at Neuchatel, Switzerland, which constitutes our leading article this month, several interesting points will be found. One which will seem rather astonishing is that the company decided to use steam-driven generators after carefully considering the possibilities of gas engines, as indicated by results obtained in other plants. We in this country have been in the habit of conceding that European gas engine practice was something to envy and to emulate as far as possible, but if it be true that the European gas engine and producer cannot make a better showing than boilers and 300-kw. steam turbines using about 16 lbs. of dry saturated steam per brake horse-power per hour, then it is quite possible that we are too modest in our estimate of the standing of American gas engines. It is also comforting to note that recent tests of American steam turbines of the same general type as those installed at Neuchatel showed an economy of 14½ lbs. of dry saturated steam per brake horse-power per hour at full load, and between 12½ and 13 lbs. of steam superheated 100° F. It is only fair to state, however, that the American turbines were tested with 28 inches vacuum and that the vacuum obtained in the Baden and Tschopeln tests were not given by the author of our article. It should be noted, though, that the initial steam pressures were 165 lbs. at Baden and 150 lbs. in the American tests. The Baden test with 68° superheat showed the creditable economy of 23.1 lbs. per kilowatt-hour, or about 14 to 14½ lbs. per brake horse-power per hour. Just here, we regret to have to say that typographical errors and careless proofreading have combined to make the table of results from the Baden tests almost unintelligible; as is unfortunately almost invariable, this was discovered too late to remedy the omissions. It may be well to explain that the numbers 38 and 28 in the second and fourth tests represent the degrees of superheat, Centigrade scale.

◆

The Electrical Congress.

The Fifth International Electrical Congress, held at St. Louis last month, was, in the main, a success, despite several unfortunate handicaps. If we except the absence of such scientific giants as Lord Kelvin, Kohlrausch and Mascart, probably the greatest single disadvantage was the location of the Congress headquarters downtown. Could the meetings have been held within or near the Exposition grounds and the members have been provided with accommodations near by, many serious delays would have been prevented, the sessions would have been longer and more fully attended and the discussions correspondingly improved. So much for the adverse features. On the other hand, under the most conservative estimate of its value, the Congress will have served to bring out some of the most able presentations of scientific and engineering investigation and development that the technical world has ever known. The running report of the proceedings which we publish in this number gives merely a general survey; it it utterly impracticable to do more in view of the enormous mass of material involved. A clean-cut comprehension of what was really accomplished can be gained only from the official printed Proceedings of the Congress, which will, of course, be issued later.

It is unfortunate that the Chamber of Delegates took no action on any propositions relating to the revision of the present system of units and standards. We had hoped that even if nothing else was accomplished by the Chamber, this one pressing question would be disposed of in a way to satisfy at least the majority of those affected by it. However, a most important step was taken in the promulgation of an entirely feasible plan for international coöperation in scientific and technical matters in the future. This plan is to establish an international electrical commission, composed of relatively few members from each coöperating nation, to constitute a sort of open court for the consideration of such questions as units, standards, nomenclature, etc. Such a commission could obviously be made much more efficient than a succession of Chambers of Delegates to Electrical Congresses, and it is to be devoutly hoped that the movement will prove successful.

◆

The Storage Battery as a Central Station Auxiliary.

Every central station man has by this time read or heard of the advantages accruing from the use of storage battery cells for taking the peak off the load in both main and sub-stations, smoothing out fluctuations in railway plants, and taking the whole station load during the periods of very small load; within a comparatively short time past, however, another application has developed—one with which the average station manager may not be familiar and which is fully as important as any of the others. This is as an auxiliary to the exciter plant in an alternating-current generating station. A storage battery floated on the exciter bus-bars of such a station is one of the most efficient safeguards against a shut-down that can be provided, and the use of such a battery renders the use of steam-driven exciters unnecessary; it also makes the use of motor-driven auxiliaries safer. It is entirely unnecessary to point out the disastrous possibilities of an accident to the active exciter in a station having all of its alternators excited from a common source; unless a reserve exciter is kept in rotation, ready to be put into service instantaneously, any serious accident to the exciter "on duty" must result in a shutdown of more than a few minutes—unless a storage battery is at hand.

As a means of developing the use of motor-driven steam plant auxiliaries beyond the present limited scope, the storage battery should also prove of much value. Alternating-current motors are extremely poor prime movers for almost every class of station pump, variable speed being practically indispensable. Moreover, it is of importance that many of the auxiliaries shall be capable of operation whether steam is available or not, and absolutely imperative that at least one of each class shall be operable whether or not the main generating plant is in operation. The first of these last-named considerations entails the use of motor-drive and all of them point to the use of direct-current motors for driving the auxiliaries, if motors are to be used. Again, it is highly advantageous to have only a single type of prime mover for the auxiliary service; but it is ordinarily unsafe to use motors exclusively for perfectly obvious reasons. Here the battery comes in strongly. By its use, the exciters may be driven by alternating-current motors and supply current to direct-current motors driving the pumps, as well as to the alternator field windings. With the battery floated on the exciter bus-bars neither momentary exciter troubles nor fluctuations in the line frequency, from whatever accidental disturbance, will interrupt or impair the excitation of the generators; the steam plant auxiliaries are assured of a continuous supply of motor current and they can be operated practically regardless of the operation of any other portion of the plant.

In this connection it may be mentioned that one of the chief drawbacks to the use of storage batteries in central stations is the crude, make-shift practice of using end-cell switches. Like all "temporary" expedients, the end-cell has remained in pernicious activity long after it should have been sent to join the wooden switchboard in well-merited obsolescence. Battery users do not need to have explained to them the serious difficulties—to put it charitably—of maintaining end cells in something approaching the condition of the remainder of the battery; but they apparently need very much to be reminded that end-cell troubles are easily obviated by the use of properly designed adjustable and reversible boosters.

◆◆◆

Utilizing the Waste Heat from Gas Engines.

In a paper read at the International Electrical Congress, by Mr. W. L. R. Emmet, the author suggested that a probably useful field for the steam turbine might be found in the utilization of the waste heat discharged in the exhaust gases and jacket water of gas engines. The author proposed to pass the jacket water into a boiler and there turn it into steam of relatively low pressure by the application of the exhaust gases to the heating surfaces of the boiler; the turbine was to be operated, of course, by the steam thus generated. The idea, substituting steam engines in general for the turbine in particular, is old and seductive, and it may be that the improvement in steam engine economy since it was first suggested has been such as to make it more nearly practical now than it was then. The present writer made the same suggestion six years ago, only to find himself antedated about ten years or so. Taking a concrete case five years ago and basing the computations on the then best practical results obtained with gas and steam engines, it was found that the increase in available work due to the addition of the steam plant could not exceed 20 per cent, and would probably not exceed 15 per cent. Mr. Emmet states in his paper that 30 per cent is a conservative estimate; if this is not too optimistic, the plan is well worth practical trial.

In actual practice, we are inclined to think, the reciprocating type of steam engine would probably prove preferable to the turbine for the reason that composite steam and gas engines could then be built, both divisions delivering power to a single shaft and, therefore, to a single generator. This arrangement would obviously have the advantages of tending to smooth out the widely-varying turning moment due to the gas engine part of the mongrel machine and of occupying considerably less floor space than two separate engines. On the other hand, there might be the disadvantage that at light loads the composite engine would be less economical than the gas engine alone. The problem is a very complex one, however, and cannot be profitably discussed offhand.

Construction of Small Dynamos and Motors.

The discussion of what might be termed "professional designing," that is, the design of machinery and apparatus from the standpoint of those who are regularly engaged in that class of work, is outside the avowed scope of this journal, and we therefore do not print articles of that character. But on account of the receipt of an almost continuous stream of letters from readers asking for instructions as to the modification of some design which we have published, or requesting aid in the design and construction of some dynamo or motor for which we have never published a design, we have decided to present a series of articles containing complete data and instructions from which any one familiar with the simple fundamentals of dynamo and motor construction may be able to lay out a direct-current machine of any size up to 16 inches armature diameter. This series of articles begins in the present number, on the next following page, and will doubtless run through eight or ten issues. As we find it impracticable to carry in stock back numbers more than a few months old, we suggest in this connection that those of our readers who are interested in this class of work will find it advisable to preserve the numbers of the paper in which these articles appear.

As stated in the introductory paragraphs of the first article of this series, it is impossible to lay down rules and formulas and to prepare accompanying tables which will enable an amateur designer to turn out a dynamo or motor that shall run sparkless, be reliable and reasonably efficient, and at the same time cost the minimum amount of money per unit of output. Since the question of specific cost is of much less importance in amateur construction than smoothness and reliability of operation, the articles have been based on a generous margin of sparklessness and ample radiating surfaces and insulation. After covering the fundamental features of "laying out" a design, the articles will deal specifically with different types of field magnet, classes of armature winding, etc., and will also include the modification of a given design to adapt it to voltages or services different from those for which it was originally intended. In short, it is hoped that these articles will enable a skilled electrical worker to go just as far in the design, construction or modification of small direct-current machines as it is possible to go without having complete knowledge of the scientific principles of dynamo design and extensive experience in the application of them.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

The object of this series of articles is to enable amateurs and students to plan and build any size of direct-current dynamo or motor from 3 inches to 16 inches armature diameter without the necessity of mastering the science of dynamo design. In order to do this, the scope of the articles will necessarily be limited to machines of conventional types and characteristics. The reader need only follow the instructions given to produce a machine which will work sparklessly at normal loads with fixed brushes.

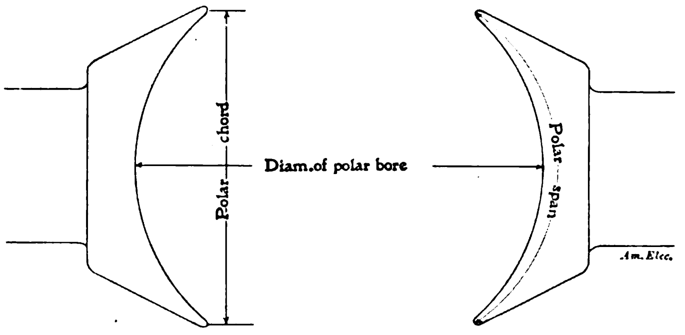

FIG. 1.

In treating the subject in such a systematic and arbitrary manner it is out of the question to insure that all of the machines built according to the rules given will show maximum output per pound of material or per dollar of cost; no hard-and-fast rules can be formulated by means of which any such results can be attained by an inexperienced builder.

The starting point in laying out a direct-current machine is the armature diameter, and by the method here employed this depends on the output of the machine and its speed. If the builder desires to obtain any particular speed, the diameter of the pole-face bore (see Fig. 1) may be estimated at the start by means of the formula

$$A = 100 \times \mathit{watts} \div \mathit{r.p.m.} \times K \qquad (1\text{-}a)$$

and the first two columns of Table III. The value of K depends on the number of poles, and is given in Table II. The watts are the product of total armature current and total armature e.m.f.; for a dynamo the watts may be taken as equal to 1.1 × the watts delivered to the external circuit at full load. For a motor, the watts may be taken directly from Table I.

TABLE I.—Motor Armature Current and Watts.

		Armature Current per wire at Different Voltages.			
H.P.	Armature watts.	110 V.	220 V.	250 V.	500 V.
¼	310	1.8	0.9	0.62	0.31
½	572	2.6	1.3	1.15	0.55
¾	790	3.6	1.8	1.6	0.79
1	990	4.5	2.25	2.	0.99
1½	1430	6.5	3.25	2.86	1.43
2	1870	8.5	4.25	3.75	1.87
3	2730	12.4	6.2	5.46	2.73
4	3575	16.25	8.13	7.15	3.58
5	4400	20.	10.	8.8	4.4
6	5215	23.7	11.85	10.43	5.22
8	6860	31.	15.5	13.74	6.87
10	8360	38.	19.	16.72	8.36
12½	10340	47.	23.5	20.7	10.35
15	12540	114 ÷ p*	28.5	25.1	12.55
20	16500	150 ÷ p*	37.5	33.	16.5

*p = number of field magnet poles.

Having found the value of A by the above formula, the diameter of the pole-face bore will be found in the first column of Table III in line with the number in the second column corresponding with the result of the formula; if there is no number in column A exactly equal to the calculated value of A, take the next larger number, and start with the polar bore corresponding to it.

TABLE II.—Values of K.

No. of field magnet poles =	2	4	6
Value of K =............	0.89	0.5225	0.3584

If no particular speed is required, the speeds given in the right-hand column of Table III will be found well adapted to ordinary service. When these speeds are used, the formula for ascertaining the polar bore is reduced to

$$B = \mathit{watts} \div 64 \times K \qquad (1\text{-}b)$$

In words, multiply K by 64 and divide the watts by the result. Having found the value of B, the polar bore is determined from Table III in the same way as before, except that the values of B are in the third column. It should be remembered that when the calculated value of A or B is not in the table, the nearest *larger* value should always be used to locate the polar bore, never the nearest smaller number.

The next step is to start on the winding. In the fourth column of Table III are numbers which are the products of the number of wires all around the armature periphery and the current in each wire. For convenience these values are called "ampere-wires." The values in the table are the greatest allowable number of ampere-wires for each diameter of pole-face bore and must not be exceeded appreciably; a small excess, such as one or two per cent, is allowable in cases where it would prevent relaying out a design. Dividing the ampere-wires by the amperes per wire obviously gives the total number of wires allowable.

Rule I.—For 110-volt dynamos of 10 kilowatts and under, and for all machines of higher voltages, the current per wire is one-half the delivered current × 1.05; for 110-volt machines of more than 10 kilowatts the current per wire is equal to 1.05 × delivered current ÷ number of magnet poles.

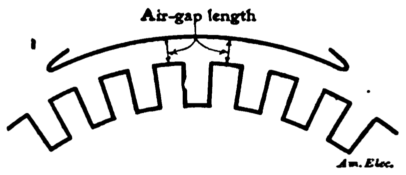

FIG. 2.

15¾	7783.	984.5	18,970	..	3/16	⅛	810
16	8192.	1024.	18,954	..	3/16	⅛	800

(This rule applies to the fundamental method on which this article is based; it is not necessarily true of dynamos in general.)

This series of articles is based on the use of slotted armature cores, and the following rules must be followed in order to obtain satisfactory results:

Rule II.—The width of an armature coil slot must not exceed three times the length of the air-gap; if possible, it should be kept within twice the air-gap length.

Rule III.—The depth of a coil slot must not exceed six times its width; if possible, it should be kept within four times its width.

Rule IV.—The air-gap length must not be less than the value given in Table III opposite the diameter of polar bore and under the proper number of magnet poles.

Rule V.—The sum of the widths of all the armature teeth, measured at the narrowest part, must be practically equal to the diameter of the polar bore.

Before proceeding farther, it may be advantageous to illustrate the application of the formulas, tables and rules thus far given. Suppose it is desired to build a 220-volt, 5-h.p. motor, to run at 1000 r.p.m., the number of field magnet poles to be four. From Table I, the number of watts is 4400; from Table II, $K = 0.5225$. Substituting these figures in formula (1-*a*) we have

$$A = 100 \times 4440 \div 1000 \times 0.5225;$$

hence, $A = 842$ and a fraction. The nearest larger number in column 2 of Table III is 861.1 and the corresponding polar bore is 8 inches. From column 4, the maximum number of ampere-wires is 8540, and from Table I the current per wire is 10 amperes; the maximum allowable number of wires, therefore, is 854.

TABLE IV.—Current-carrying Capacity of Round Armature Wires. B. & S. Gauge.

Wire size.	At Table III speeds.	At lower speeds.
8	40	34
9	32	27
10	25.6	21.7
11	20	17
12	16	13.6
13	12.8	10.9
14	10	8.5
15	8	6.8
16	6.5	5.5
17	5.1	4.3
18	4.1	3.5
19	3.3	2.8
20	2.6	2.2
21	2.1	1.78
22	1.7	1.45
23	1.35	1.15
24	1.1	0.93
25	0.9	0.76
26	0.7	0.59
27	0.56	0.47
28	0.46	0.39
29	0.36	0.31
30	0.29	0.25

From Table IV, the size of wire necessary to carry 10 amperes at speeds less than those in Table III is No. 13.

From column 6 of Table III, the air-gap is 3-32 inch, and according to Rule II, the width of the armature coil slots must not exceed 9-32 inch. From the left-hand section of Table V, the nearest slot width for No. 13 wire is 0.21 inch, which takes one wire only. The slot depth, according to Rule III, must not exceed 6 × 0.21 = 1.26 inches; the nearest slot depth in the right-hand section of Table V for No. 13 wire is 1 9-32 inches, which will take 12 wires.

The number of wires required is 854, as just stated. Each slot will take 12 wires (1 wide x 12 deep), and the slots must all contain the same number of wires each; therefore it is not practicable to use exactly 854 wires. The nearest practical number is 852 wires, which will occupy 71 slots.

The polar bore being 8 inches and the air-gap 3-32 inch, the armature core will be 8 — 3-16 = 7 13-16 inches. The slots being 1 9-32 inches deep, the diameter of a circle drawn through the narrowest part of the teeth will be 7 13-16 — 2 9-16 = 5¼ ins. The circumference of this circle is 16.49 inches, and of this circumference the slots occupy 71 × 0.21 = 14.91 inches; this leaves only 16.49 — 14.91 = 1.58 inches for all the teeth, which is manifestly absurd, even without considering Rule V. It here becomes evident that the armature may have to be increased in diameter, which may increase the air-gap. The method of making this correction will be explained in the next article.

AN INCONSISTENCY IN THE NATIONAL ELECTRICAL CODE.

BY C. R. JAMES.

The National Underwriters' Electrical Code has much to say about the construction of lamp sockets and goes into many details. It seems strange that the committees which have formulated this code should have given so much attention to the socket itself and utterly ignored a defect which is common to the great majority of Edison sockets. This defect is that the brass shell of the Edison lamp base usually is not by any means entirely protected by the lamp socket, with the result that a part of the lamp base which is especially liable to be brought in contact with persons and grounds is exposed without any protection whatever. The accompanying photograph of an Edison socket with lamp illustrates this point. This lamp and socket are not by any means exceptional, as both are of standard markes now on the market, hundreds of thousands of which are now in use. The live lamp base is exposed for a distance of about 3-16 of an inch. The majority of electrical engineers seem never to have noticed this detail, but they would have done so quickly had they received shocks in attempting to turn on a drop light in a damp basement with the exposed part of the lamp base on the non-grounded side of the circuit. The exposure of live metal is sufficient on the socket shown, so that it is not only possible, but quite probable, that any one taking firm hold of the socket would make contact with it. Of course, the voltage on an ordinary lamp socket is not dangerous to the average person, but it is far from being pleasant to receive a shock even from such a low voltage, and further than this, there is danger that fires may be caused by the live lamp base coming in contact with some grounded conductor. In view of the great precautions that are taken to prevent defective lamp sockets from causing fires, it looks decidedly absurd to "strain at a gnat" in the socket itself and "swallow a camel" in the lamp base which is screwed into the socket. One would think that the Edison lamp base had been in use enough years so that little defects of this kind would have been weeded out. All that is necessary is either a lengthening of the socket shell and lining or a shortening of the lamp base.

SELECTIVE RINGING SYSTEMS.

The Kellogg Harmonic System.

BY A. DALLAM O'BRIEN.

The question as to the advisability of the use of party lines in telephone central offices may at the present stage in telephone development be considered as being fairly settled. Subscribers whose use of the telephone is small demand service at a low cost and it is to this class of customers that the party line particularly applies. The objections that may be offered to this class of service on the part of the subscriber are all insignificant compared to the annoyance due to signal ringing and the consequent necessity of being on the alert whenever the telephone rings; in addition to this there is a most decided temptation to listen to conversations which may originate from another station on the line. After a

thorough trial of signal ringing systems, it has become very thoroughly realized that the successful party line system—successful because it satisfies the users—is the selective arrangement in which only the station desired is called and in which there is no intimation to the other stations on the line that a call is being made.

There are in use at the present time a large number of selective systems. In some of these the step-by-step method is employed; others use currents of different strengths and polarities to actuate specially polarized bells, and in a system recently described in this paper the use of properly designed resonance circuits, with a combination of an inductance and a capacity, render the connected bells susceptible only to a predetermined current frequency.

It is the purpose of the present article to describe the Kellogg selective system adapted for use with four party lines or lines having less than four stations connected to them. The selective feature depends upon the harmonic vibration of a reed or rod when actuated by an alternating current whose frequency corresponds with the frequency of the vibration of the rod in question. The principle of operation is so thoroughly known and understood that it is not necessary to explain it at length. In the operation of the selective system under consideration alternating currents having the following frequencies are employed: 2000, 4000, 6000 and 8000 alternations per minute, the current being furnished as later described.

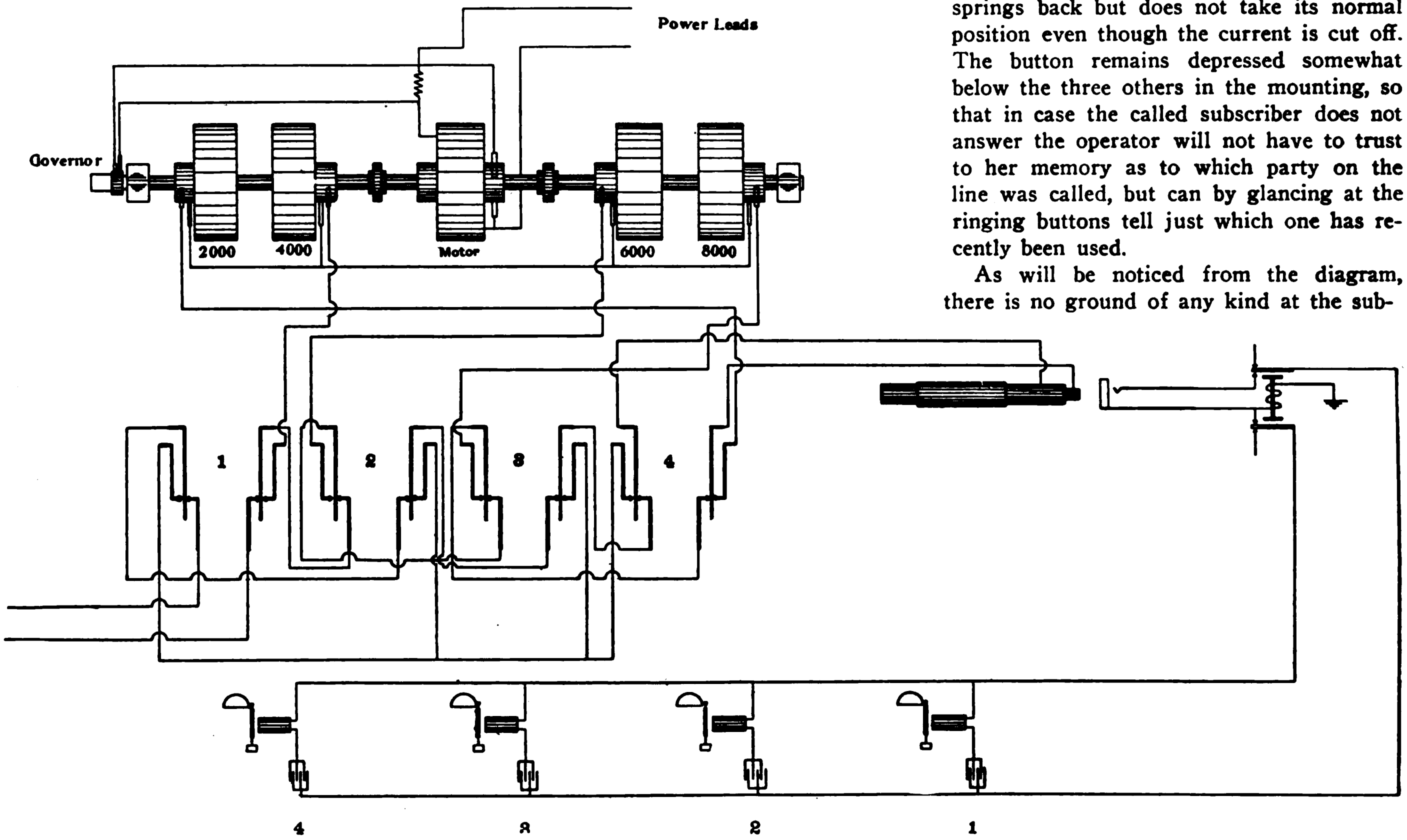

FIG. I.—GENERAL ARRANGEMENT OF CIRCUITS IN KELLOGG SELECTIVE RINGING SYSTEM.

The ringers or bells at the sub-stations differ only in the size of the tapper and the length of the tapper arm. The bells are solidly constructed and are strongly polarized by means of a powerful permanent magnet, which with the bell coils and the armature are mounted on a brass and iron frame, the tapper being suspended from the lower end of the armature by a flexible steel spring. Each bell is equipped with a single gong so fastened to the mounting that it may be adjusted for the different size tappers. The general arrangement of the circuits and equipment is shown diagrammatically in Fig. 1. In the central office is located the multicycle ringing set which consists of four generators mounted on the same shaft with a direct-current motor, the generators having respectively two, four, six and eight poles, and as the motor runs at a speed of 1000 revolutions per minute the generators furnish currents at frequencies of 2000, 4000, 6000 and 8000 alternations per minute. The size of the generators in the ringing set depends upon the size of the central office and the consequent demand for ringing current. As will be noted from the diagram, one side of each of the ringing machines is grounded.

The selective ringing buttons are arranged four in one mounting and are placed in the keyboard in the usual way, so that the answering cord of each cord circuit is connected through all four of the keys. The arrangement of the keys as they are usually wired is shown in the diagram, the keys being numbered 1, 2, 3 and 4 to correspond with the numbers of the sub-stations. The outside or ringing springs of one side of all four keys are connected together, the common connecting wire being grounded. The other ringing spring on each key is connected to a lead from one of the machines; the usual arrangement being to connect No. 1 to the machine which furnishes current at 4000 alternations per minute, No. 2 to the 6000-alternation current, No. 3 to the 8000-alternation current, and No. 4 to the 2000-alternation machine. The sub-stations may be connected to the line in any order, not necessarily as shown in the diagram, the only essential being that the bells are bridged across the line in series with a condenser in each case. As previously stated, the one point of difference between the bells at the different stations lies in the size of the tapper and the length of the spring which connects the tapper to the armature. As might be expected, the length of the spring and the size of the tapper reach their maximum with party No. 4, where the frequency of the ringing current is 2000 alternations per minute, and their minimum with party No. 3, where the ringing current has 8000 alternations.

In the operation of this system, when it is desired to call a certain station on a party line, the calling plug is inserted in the jack of the desired line and the button corresponding to the station to be called is depressed. As long as the operator holds the ringing button in a depressed position, ringing current will continue to flow over the line and signal the desired station. Upon releasing the ringing button, it springs back but does not take its normal position even though the current is cut off. The button remains depressed somewhat below the three others in the mounting, so that in case the called subscriber does not answer the operator will not have to trust to her memory as to which party on the line was called, but can by glancing at the ringing buttons tell just which one has recently been used.

As will be noticed from the diagram, there is no ground of any kind at the sub-station, the ringing current returning to the office over a metallic circuit and finding its ground at the office itself. In order to further identify the buttons of the four-party key, they are colored black, green, red and blue, so that after a short time the significance of the different colors is at once apparent to the operator. Where the party lines connected to the central office form a considerable portion of the total number of connected lines, the question of equipping each cord circuit with a selective key is one that is not likely to arise. There are, however, numerous instances in practice where the party lines form only a small portion of the exchange equipment, and in these cases it becomes a question as to the policy of equipping all the cord circuits with selective keys. From a purely operating standpoint, there can be no question but that the better practice would be to use the selective equipment throughout, but owing to the increased cost of these keys over the ordinary type, the selective ringing is often accomplished by using the ordinary key on all the cord circuits and equipping each operator's position with a master key in addition. The master key is in reality a quadruple throw switch, through which the ringing strap is connected to the keys in the keyboard. The contact points of the master key, or switch, are connected to leads from the generators which furnish the different frequency currents, and by the operation of this key current of any desired frequency may be connected to the ringing keys in the keyboard. It is, of course, evident that with this method the operation of ringing a party line involves two operations on the part of the switchboard operator, and that in consequence the operator's efficiency or the number of calls which she can complete in a given time is decreased. From this, it will be evident that whenever the conditions do not absolutely prohibit the use of a complete equipment of selective keys, it is by all means desirable to use them, as the operator's efficiency is a very large factor in the successful operation of a telephone plant. It is not necessary with this system to provide a separate ringing machine for furnishing the signalling current for ringing the individual lines, as the 4000-alternation current will answer perfectly for this purpose, and consequently, the No. 1 key can be used for ringing on all the direct lines. It is, of course, of the greatest importance in a system of this kind, which depends for its successful operation upon the harmonic vibration of the tappers, that the frequency of the current should remain practically constant. As this system is ordinarily used, the four generators are mounted on the same shaft with a motor to which current is furnished from some outside source. The average commercial power circuit is subject to more or less variation in voltage, and consequently, in order to keep the speed of the motor constant it is absolutely necessary to provide a governor which will compensate for the voltage variations in the circuit.

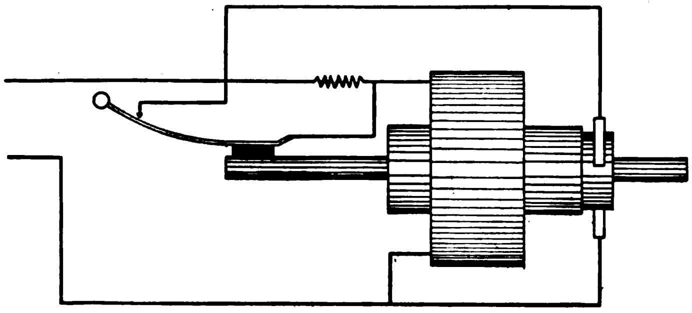

FIG. 2.—MOTOR-SPEED GOVERNOR.

With this system a governor has been designed to control the speed of the motor, and a test made on this apparatus has proven its ability to regulate the speed of the motor within 2 per cent of the normal, while the line voltage varies through a range of from 20 per cent above to 20 per cent below the normal voltage. The general features of this governor and the principle upon which it operates are shown in the diagram of Fig. 2. On the end of the ringing shaft is attached a spring carrying a weight which is so arranged as to be thrown outward by centrifugal force and open and close a shunt circuit around a resistance in series with the field coils of the motor. As is well known, the introduction of a resistance in the field circuit results in decreasing the strength of the field and increasing the speed of the motor, while in this particular case it is desired to keep the speed of the motor constant at 1000 revolutions per minute.

When the ringing set is installed, the maximum variation in the voltage of the power circuit is determined and the motor designed so as to run at a speed below the normal when the resistance is cut out of circuit and when the voltage of the power circuit is at its maximum, and to run above normal speed when the power circuit obtains its minimum voltage and the resistance is cut into the field circuit. This being effected, the governor is adjusted so that the motor will run at its normal speed of 1000 revolutions at the normal voltage on which it is intended to operate. It will be apparent that as the voltage of the power circuit varies, thus causing the speed of the motor to rise and fall, the resistance in the field circuit will be cut in or out with a result that the speed of the motor will remain practically constant and the harmonic action of the system preserved.

For use in small exchanges, where the expense of a ringing set such as that described would render it prohibitive, a rotary pole changer has been designed to answer satisfactorily the selective requirements. This pole changer consists of a motor directly coupled to a direct-current generator, the set being equipped with the same type of governor as that used with the regular equipment. The current from the generator is led by means of two slip-rings to four commutators which serve to interrupt it at the four desired frequencies.

To adapt this system to a switchboard which is already in service is a comparatively simple matter and necessitates but small changes in the central office equipment. A multiple ringing set must, of course, be installed and the ringing and listening keys replaced by selective keys, or each position equipped with a master key. In addition to this, slight changes must be made in the wiring of the keyboard and ringing leads from each of the four machines brought to each position. The absence of all parts which may be continually in need of adjustment renders the system one easily maintained and one not liable to constant troubles. That the system is not in the experimental stage is attested by the fact of its use in exchanges serving upwards of 50,000 subscribers.

◆

PRACTICAL MANAGEMENT OF ROTARY CONVERTERS.

BY F. P. DE WILDE.

The rotary converter is the connecting link between the direct-current and alternating-current systems. It combines in the armature and field windings of a single machine the functions of two machines—the motor-generator. It may be regarded as a synchronous motor driving a direct-current generator, or it may be inverted and used as a direct-current motor driving an alternating-current generator. The ratio between the alternating and direct-current voltages of a rotary converter depends upon the number of phases, the wave form of its alternating current, and the field excitation of the converter. With a sine wave alternating supply the ratios of conversion are approximately as follows: Single phase, 0.71; two phase, 0.71; three phase, 0.61; six phase, 0.71, with the star connection, or 0.61 with the double delta connection.

There are two general methods employed in starting rotary converters; one is by the use of an auxiliary alternating-current starting motor and the other by starting the machine as a plain shunt-wound motor, using a short-circuiting switch on the series field winding if the machine happens to be compound-wound. In following the former method (Fig. 1), see that the alternating-current and direct-current brushes are all

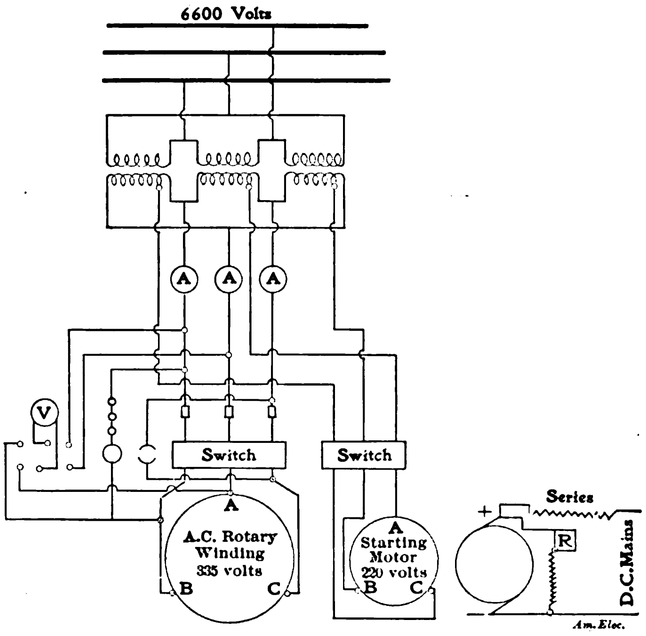

FIG. 1.

in their correct position; next, see that all switches are open on both the alternating-current and direct-current sides and that the resistance of the rheostat is all cut in the field circuit. Then close the alternating-current main circuit-breakers and see that the plugs to the synchronizing lamps, or synchronoscope, are in and that the lamps burn dimly, also that the plug for the direct-current voltmeter is in. Start the rotary by closing the starting motor switch and build up the direct-current voltage by cutting out resistance in the rheostat until the voltage is equal to the bus-bar voltage. Now move the main alternating-current switch blades to within an inch or so of the jaws, so that they may be thrown in more quickly at the proper moment. Now note the lamps or synchroscope and adjust the speed by means of the field rheostat until the lamp dims slowly and regularly. It may be necessary to shift the direct-current brushes back from the neutral point in order to get the proper speed. When the lamps show pulsations at the rate of about one every ten seconds the switch should be closed quickly, and this should be done when the lamps are getting dark rather than when they are receding from synchronism. Now open the starting motor switch and adjust the converter field excitation so as to get minimum current in the alternating-current ammeters. Next close the direct-current circuit-breaker and switches, and see that the brushes are in the proper position.

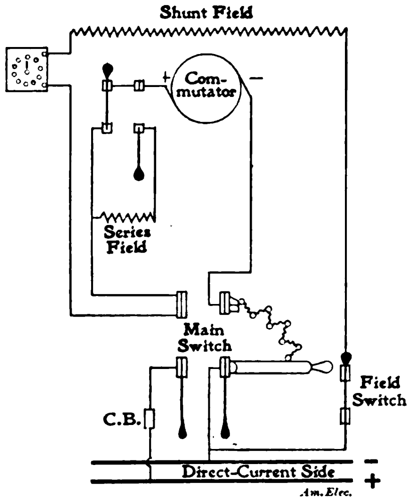

FIG. 2.

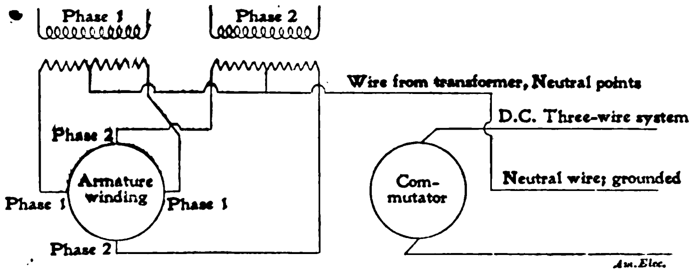

FIG. 3.

To start a single converter from the direct-current side, first see that all switches are open, that the direct-current brushes are all properly set, and that the series field is cut out or short-circuited. Next close the alternating-current circuit-breaker and positive switch. Close the field switch with all the rheostat resistance cut out, and try the field poles to see that they are magnetized. Now start the converter as a direct-current motor by cutting out the starting resistance slowly; when this is all cut out close the negative switch. Then adjust the speed to synchronism by means of the field rheostat and the synchronizing lamps. It is also necessary to have the alternating-current voltage of the rotary converter equal to that of the alternating-current supply; shifting the brushes will assist to a slight extent in making this adjustment. When the voltage is correct and the lamps indicate the proper phase relations, close the alternating-current switches. Now adjust the rheostat for minimum alternating current and set the direct-current brushes at a non-sparking position. In the foregoing it is assumed that the circuit-breaker is on the positive side and the starting resistance across the terminals of the negative switch, as indicated in Fig. 2.

In starting a second converter to be run in parallel with another, the same method is used as in starting a single converter, using the synchronizing and voltmeter plugs on the panel of the converter to be started. In addition, however, care must be taken in building up the direct-current voltage to make sure that the machine being thrown in builds up in the same direction as that of the other rotaries and that the brush-holders are in similar positions. Next, synchronize, as already explained, and after having thrown the machine in, open the starting switch. In paralleling the direct-current side, it is better to close the switches when the load on the running converter is minimum. If the load on a converter having a strong series field winding is constant and heavy, it is better to short-circuit or cut out the series windings on both machines while throwing them together on the direct-current side; otherwise the sudden division of the load will cause a rush of current between the machines which will be very likely to result in the reversal of the polarity of the first converter. Now regulate the alternating current by means of both rheostats to obtain the minimum current. The division of the load between the converters may be regulated to a slight extent by shifting the direct-current brushes. This method of paralleling is also used where the starting motor method of bringing the machines in synchronism is used.

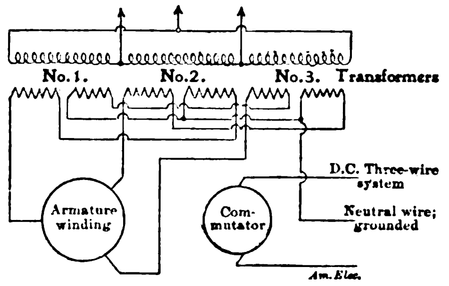

FIG. 4.

It will sometimes happen that a machine is reversed. This can easily be rectified by recharging the field magnet. Cut in all the resistance in the field circuit, disconnect the field winding from the brushes and excite it in the right direction from another source, such as the other operating machines. It is assumed that the main direct-current switch is left open.

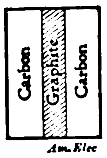

FIG. 5.

It will sometimes happen that only one alternating-current circuit-breaker comes out. If the machine stays in step, pull out the switch corresponding to this leg, throw in the circuit-breaker and watch the ammeter in this leg; now throw in the switch to see if this leg is working. If the alternating-current circuit-breakers come out and the machine falls out of synchronism, open the direct-current circuit-breaker and all switches immediately. Some rotaries are provided with tripping coils on the circuit-breakers which open the breakers and prevent the rotaries from racing at this point. The tripping coils are usually energized by means of a little centrifugal governor on the end of the converter shaft which closes the circuit at a certain speed. Without such a precaution, if two or more converters were run in parallel on the direct-current side and one should fall out of step on the alternating-current side, the other machines would commence to feed this one and drive it as a motor at a dangerous speed.

Flashing may be due to any one of several causes, such as overloading or the failure of the alternating-current supply circuit; it may also occur by reason of several converters operating on the same transformer bank. When this method is used, it is sometimes impossible to operate the machines without undue sparking and blackening of commutators due to the exchange of heavy currents between the direct-current sides. This can be mitigated to a great extent by providing for each converter a separate set of transformer secondary windings, all in one bank of transformers.

One of the most prolific causes of flashing is the failure of the alternating-current voltage across the collector rings. This sets up an abnormal voltage between the positive and negative brush-holders, which will make itself known by short-circuiting the commutators, blistering the brush-holder boxes, and dropping hot metal on the commutators which causes the coils to burn out almost every time this occurs. The writer advocates setting the brush boxes farther away from the commutator than usual, so as to reduce this tendency, but the only complete remedy is to connect the neutral points of all the transformer secondaries together and to ground, as shown in Figs. 3 and 4. This arrangement is often used on rotary converters for three-wire direct-current service, and is a most effective remedy for the trouble just mentioned. The writer has known cases in which the commutator had to be turned off about once every sixty days. The machine, a 60-cycle rotary, would get flat spots and the brushes run red-hot at times when the machine was only carrying normal load; pure carbon brushes were used on the commutator, the armature was correctly centered, the brushes correctly set, and all equi-potential points in the armature were connected together by cross connectors. The writer then took a hacksaw blade and cut narrow slits about 5-16 inch deep into the brush faces parallel to the mica in the commutator. The commutator was then put into good shape, and the slit brushes applied; the machines acted very differently and the commutators commenced to gloss up and gave very little trouble thereafter. I have always believed that nine-tenths of the commutator troubles are brought about through the commutator not being properly cared for. I have seen commutators that were actually corrugated, due to the bars wearing down faster than the mica. This trouble can be more or less avoided by sand-papering the commutator at regular intervals with very fine carborundum paper, and care should also be taken to see that the commutator has been properly tightened, which should be done after a long hot run, so that all the plastic material in the mica between segments will have softened and made it possible to take out the elasticity. If this is properly done there will be little tendency for the commutator to show high and low bars. Carbon brushes are made in a great many varieties of compositions, but the best brush the writer has ever used is a soft carbon brush with about 10 per cent. of graphite in it—just enough to make it self-lubricating. One large carbon company is now making a special brush with a strip of graphite about ⅛ inch thick built up in the brush as shown in Fig. 5. This brush is very satisfactory and the commutator requires practically no attention. The conductivity of the brush is good and it offers a high resistance to all local currents. The best results with any carbon brush are obtained with 30 to 35 amperes per square inch of face. The brush tension should never exceed 2 pounds per square inch; higher densities and pressures cause undue temperature rise at the commutators.

Hunting is a very troublesome factor, even to this day, with 60-cycle rotary converters. Various methods have been devised to overcome this trouble, such as using copper pole shoes which are embedded in one or more slots through the laminated pole-face and entirely surrounding the poles. This is usually effective, but not always. Another fairly effective method is to make the pole pieces of cast steel; these act as dampers and help commutation a great deal. Hunting usually manifests itself first on the rotary alternating-current ammeters, the needles of which will commence to swing backward and forward; then the brushes will give a peculiar squeak during the oscillations in speed; the alternating-current side of the rotary acts as a generator and a motor alternately. The distortion of the fields due to hunting results in "flashing," which can usually be stopped, however, by giving the machine a very stiff field, and a very effective damper has been found in the starting alternating-current motor which is simply thrown on the lines; or an idle induction motor is kept floating on the transformer secondaries.

The writer has always favored the use of a starting motor for bringing a rotary into step. Starting up from the direct-current side has several disadvantages; it requires a source of direct current by means of which the converter is started as a simple shunt-wound motor, and also requires a short-circuiting switch to cut out the series winding, if the converter happens to be a compound-wound machine, to prevent changes of speed being caused by changes in the armature current flow. The machine should also have switches by means of which the armature may be disconnected from the transformer secondaries; if the transformers are left connected, the armature winding will be more or less short-circuited by the secondaries of the transformers. A two-phase rotary can be in such a position as to require an enormous starting current; in fact the armature presents a short-circuit to the source of applied current and the alternating-current side must therefore be disconnected from the transformers in all two-phase rotaries. Even in three-phase rotaries this trouble is encountered, but to a less extent. A rotary converter transforming from direct current to alternating current has no constant speed, its speed being determined like that of a direct-current motor; the speed is therefore governed by the strength of the field and is consequently affected by the reaction of the armature current upon the field. The converter, therefore, will speed up excessively if a heavy induction load is thrown on the alternating-current side. This, however, may be overcome by exciting the converter from a generator the speed of which varies with that of the converter, particularly if the field of this generator is unsaturated at normal voltage. Then any change in speed of the rotary converter will cause a corresponding change in the exciting voltage, and strengthen the field of the rotary; its speed will then be independent of the amount or nature of the load. This method is used by the Westinghouse Company. To shut down a rotary converter operating in parallel on both sides, simply open the direct-current circuit-breaker and the direct-current switches; then open the alternating-current circuit-breaker and the alternating-current switches; cut in all the field rheostat and pull out synchronizing plugs. This applies to both methods of operating rotaries.

◆

THE THREE-WIRE GENERATOR.

BY GEORGE W. MALCOLM.

In my last article* it was stated, with a view to simplifying the elementary discussion, that all of the current returning to the generator by way of the neutral wire, when the load is unbalanced, passes first through one half and then through the other half of the balancing coil, dividing through both halves only when the e.m.f. delivered to the coil by the armature is zero, as indicated in Fig. 11. This is not strictly true. The arrows in Figs. 10 and 12 indicate accurately the direction of the e.m.f. delivered by the armature and that of the magnetizing current of the balancing coil, but not the flow of the neutral current.

When the load on the system is exactly balanced, no current flows in the neutral, of course. Then there flows in the balancing coil a small magnetizing and core-loss current supplied by the armature. The alternating magnetism in the core induces a counter e.m.f., just as in the case of the primary winding of a transformer on open secondary circuit. This e.m.f. is just enough lower than the armature e.m.f. to allow the exciting current to flow. Now, if the load be unbalanced, as indicated in the diagrams, the larger load being on the positive side of the system, the neutral current will tend to return to the negative brush of the dynamo through the then negative half of the balancing coil; when one-half of the current passes that way, however, it will have increased the magnetism of the core to such an extent as to increase the counter e.m.f. of the coil sufficiently to prevent any more current flowing in that half of the coil and to overcome the applied e.m.f. in the positive half just enough to allow the remainder of the neutral current to flow there. (The polarity of the coil being alternating, the terms positive and negative apply to that half which is positive or negative at the instant under discussion). Consequently, the neutral current divides with practical equality between the two halves of the balancing coil in all positions of the armature, the current in one-half of the coil exactly neutralizing that in the other half and leaving the core affected only by the exciting current supplied from the armature.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.

The ninth annual convention of the International Association of Municipal Electricians was held at the Grand View Fraternal Hotel, St. Louis, September 13 and 14. After an executive session at 8:30 on the morning of the 13th the first regular meeting was called to order. In his opening address, President A. C. Farrand referred to the appropriate time and place of the meeting, in that they afforded opportunity to study the electrical exhibits at the Fair and to attend meetings of the International Electrical Congress. Mr. Walter M. Petty, chairman of the executive committee, reported that there was nothing requiring immediate attention. He did, however, speak of the need of making the name of the Association and its purposes better known. His remarks led to the appointment of a committee to advertise the Association.

The first paper presented for discussion was that of Mr. A. S. Hatch, of Detroit, on "Street Lighting." The methods of placing lamps as well as the different lamps employed were discussed. The ideal lighting system, Mr. Hatch said, was that of employing arc lamps on high towers. This gives even and well-distributed illumination.

The next paper presented was that of Mr. Adam Bosch, of Newark, N. J., the subject being "Limitations of the Telephone for Fire Alarm Purposes." The paper led to a spirited discussion. It was, however, the general opinion that the telephone should be used only as an auxiliary in reporting fires; that in case of fire, the fire alarm box should be pulled first and the telephone used, if necessary, afterward. The excited condition of the person telephoning, the similarity of the names of streets, and the indistinct pronunciation of the foreign element all tended to make the telephone more or less unreliable.

In the absence of Mr. William H. Thompson, of Richmond, Va., a paper prepared by him on "The Inspection of Theatres from an Electrical Standpoint" was read by the secretary, Mr. Frank P. Foster. Discussion of the paper was deferred to the next meeting, the Association adjourning until the following morning.

The session on Wednesday morning was taken up with the presentation and discussion of a paper by Mr. Walter M. Petty, of Rutherford, N. J., on "Methods of Testing." He went into a great many details as to the proper way of making periodic and systematic tests of fire alarm circuits, etc., and cited the practices adopted in various communities.

The election of officers for the ensuing year resulted as follow:

President, W. M. Petty, of Rutherford, N. J.; first vice-president, J. B. Yeakle, of Baltimore, Md.; second vice-president, G. H. Holderman, of Indianapolis, Ind.; third vice-president, C. E. Diehl, of Harrisburg, Pa.; fourth vice-president, Charles Greenwald, of New Brunswick, N. J.; treasurer, G. F. Macdonald, of Ottawa, Can.; secretary, F. P. Foster, of Corning, N. Y. Executive Committee: J. Murphy, Cleveland, Ohio; William Crane, Erie, Pa.; M. J. Donohue, Niagara Falls, N. Y.; A. S. Hatch, Detroit, Mich.; C. L. Williams, Laurel, Miss.; A. C. Farrand, Atlantic City, N. J.; W. H. Thompson, Richmond, Va.; F. C. Mason, Brooklyn, N. Y., and J. S. Craig, Toronto, Can. Finance Committee: W. H. Bradt, Troy, N. Y.; James Grant, New Haven, Conn.; T. C. O'Hearn, Cambridge, Mass., and J. D. Hall, Peoria, Ill.

It was voted to hold the next convention at Erie, Pa.

Lessons in Practical Electricity

TRANSFORMER CONNECTIONS.

Two or more transformers built to operate at the same potential and frequency may be connected together in a variety of ways; in fact, the primary and secondary terminals may each be considered exactly as the terminals of direct-current dynamos, with certain restrictions. The two principal precautions which must be observed in combining transformer terminals are that the terminals must have the same polarity at a given instant, and the transformers should have practically identical characteristics. The latter condition is not absolutely essential, but it is emphatically preferable. For example, if a transformer which has 2 per cent regulation be connected in parallel with one which has 3 per cent regulation, as indicated in Fig. 1, at no-load the transformers will give exactly the same e.m.f. at the secondary terminals, but at full load one will have a secondary e.m.f. of, say, 98 volts, while the other has an e.m.f. of 97 volts. The result is that the transformer giving only 97 volts will be subject to a back e.m.f. of one volt from its mate. This will not cause excessive current to flow backward through the secondary winding of the low-voltage transformer, but it will disturb the phase relations and lower the power-factor and efficiency of the combination; in such a case it is much better to work the secondary circuits of the two transformers separately.

In case the transformers have practically the same characteristics it is necessary, as stated above, to make sure that the secondary terminals connected together have the same polarity at a given instant; it is not necessary to find out definitely what the polarity is, merely that it is the same for both terminals. This can be easily done by connecting two of the terminals, as shown in Fig. 2, by a small strip of fuse wire, and then touching the other two terminals together. If the fuse blows then the connections must be reversed; if it does not, then they may be made permanent. It is seldom advantageous, however, to operate transformer secondaries in parallel; occasionally it may be necessary as a temporary expedient, but where the load is such as to require a greater capacity than that of a transformer already installed, it is much better to replace it by a larger transformer than to supplement it by an additional transformer of its own size.

All modern transformers have the secondary windings divided into at least two sections, which may be connected up either in parallel or in series. If the secondary e.m.f. of a transformer having two sections is 100 volts with the terminals in parallel, then connecting them in series will give 200 volts at the free secondary terminals, as indicated in Fig. 3. If the transformer be of the core type, and the two sections of secondary winding be wound on different limbs of the core, as in Fig. 4, it will be advisable, if the secondaries are to be operated in parallel, to make the connections ample and permanent, so that there will not be any liability to a difference between the current flowing in one secondary winding and that flowing through the other.

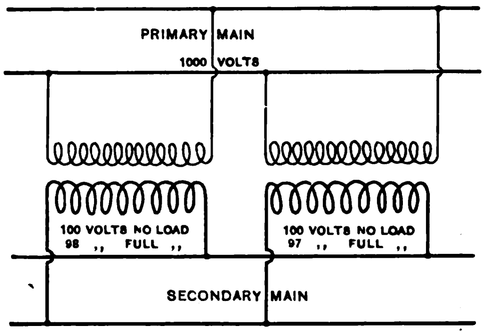

FIG. 1.—UNLIKE TRANSFORMERS IN PARALLEL.

Still referring to a transformer which has the two secondary sections on different legs of the core, if the secondary terminals are connected up to a three-wire distribution, as shown diagrammatically in Fig. 5, it is advisable to make the fuse, *Fc*, in the middle wire, considerably smaller than necessary to pass the normal load in either side of the circuit. The reason for this is as follows: Should the fuse, *Fa*, be blown, the secondary circuit through the section, *Sa*, will be open, and the corresponding half of the primary winding, *Pa*, will have a much higher impedance than the half of the primary winding, *Pb*, the inductance of which is so greatly neutralized by the load on the secondary winding, *Sb*, as explained in previous lessons. The result will be that the counter e.m.f. of the primary section, *Pa*, will be very much greater than

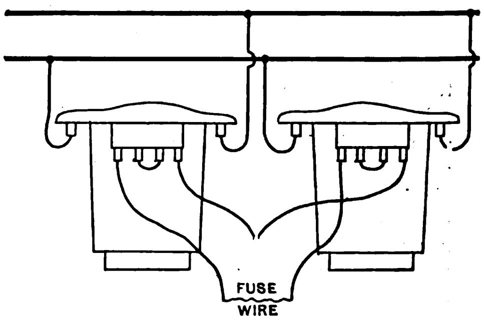

FIG. 2.—COMPARING INSTANTANEOUS POLARITY.

that of the section, *Pb*, and as the sections are in series the current must be the same through both halves of the winding; the drop or difference of potential, therefore, between the terminals of *Pa* will be much higher than that between the terminals of *Pb*, consequently the secondary voltage of *Sb* will be greatly lowered and the service impaired. As the primary winding, *Pa*, is designed to take only one-half of the total impressed e.m.f., the unbalancing referred to will subject it to a considerably higher e.m.f. than the normal value; consequently the magnetic density in that leg of the transformer core will be much higher than normal, and the transformer will heat disastrously.

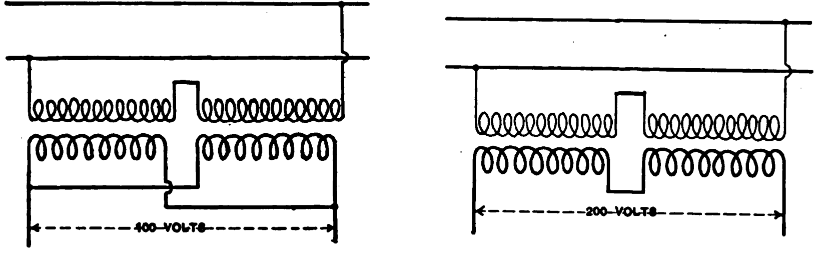

FIG. 3.—SECONDARY CONNECTIONS FOR DIFFERENT VOLTAGES.

If the fuse, *Fc*, in the middle wire be made, say, one-half the capacity of each of the other fuses, this condition will be relieved by the blowing of this fuse, and as the lamps in the live circuit would not be anywhere near candle-power if the circuit remained intact, the blowing of the middle fuse will not be any disadvantage to the user of the lamps. Some makers avoid the contingency just described by dividing each secondary coil into two sections and connecting a section on one leg in series with a section on the other leg of the core, so that current applied to either pair of the secondary terminals will circulate about both legs of the core.

In the case of two-phase distributions each circuit may be treated as entirely independent of the other so far as the transformers are concerned. Two transformers are used, one transformer being connected to one primary phase and supplying one secondary phase, and the other transformer being connected to the other primary phase and supplying the other secondary phase, as indicated in Fig. 6, exactly as though each primary and secondary phase were an ordinary single-phase system independent of the other phase. In such cases it is possible for the two phases to remain electrically independent throughout the system, although it is not customary to thus arrange the wiring.

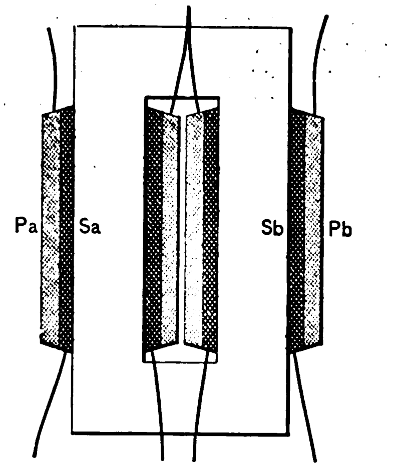

FIG. 4.—ORDINARY CORE-TYPE WINDING.

A method of connection commonly used to obtain economy in wiring is that shown by Fig. 7, where the primaries of the transformers are connected independently to the two phases and the secondaries are joined to a three-wire distribution, the middle wire being about one-half larger than each of the two outer wires. In the former case, Fig. 6, it makes no difference which secondary terminal of a transformer is connected to a given secondary wire, so long as no transformers are used in multiple. For example, referring to the diagram, the left-hand secondary terminal of transformer *A* could just as well be connected to the lower wire of the secondary phase, *A*, and its right-hand terminal connected to the upper wire, the only requirement being that the two pairs of mains shall not be "mixed," that is to say, transformer *A* must not be connected with one secondary terminal to phase *A* and the other to phase *B*. In the case shown by Fig. 7 there is not quite so much freedom in making connections. One secondary terminal of each transformer must be connected to one of the outer wires and the other two terminals must be both connected to the larger middle wire of the secondary system. It makes no difference, however, which two secondary terminals are joined, so long as the other terminal of each transformer is connected to an outer wire of the secondary system.

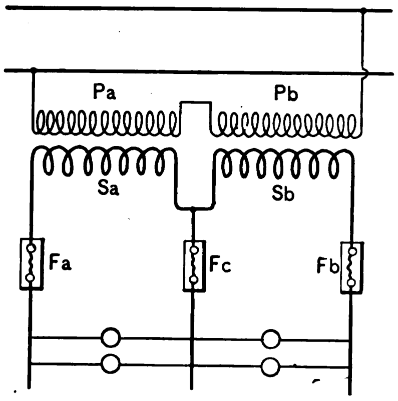

FIG. 5.—THREE-WIRE SECONDARY SERVICE.

The methods of making three-phase connections are more rigid, as the three phases are inseparably interlinked. There are two ways of connecting up the primaries and secondaries, one known as the "delta" connection and illustrated diagrammatically by Fig. 8, and the other known as the "star" connection and illustrated by Fig. 9. In both diagrams the line wires are lettered *A*, *B* and *C*. Fig. 10 shows the primaries and secondaries connected up delta fashion, corresponding to Fig. 8, and Fig. 11 shows them connected up star fashion, corresponding to Fig. 9. In both of the latter sketches the secondary wires are lettered to correspond with the respective primary wires. When the primaries are connected up delta fashion, the voltage between the terminals of each primary winding is the same as the voltage between the corresponding two wires of the primary circuit, and the same is true of the secondary transformer terminals and circuit wires.

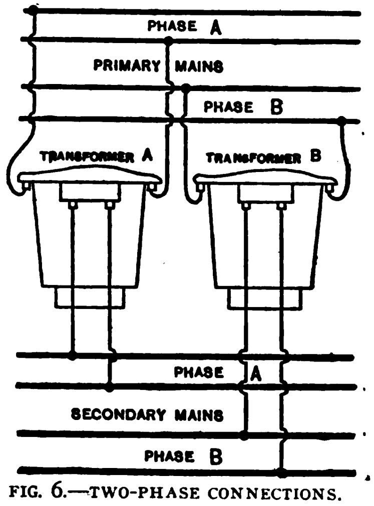

FIG. 6.—TWO-PHASE CONNECTIONS.

The current, however, flowing through the transformer winding is less than the current in the line wire, for the reason that the current from any one line wire divides between the windings of two transformers. For example, in Figs. 8 and 10, part of the current from the line wire *A* will flow from *A* to *B* through the left-hand transformer, and part from *A* to *C* through the right-hand transformer; if the current in the line wire, *A*, is 100 amperes, the current in each transformer winding will be 57.735 amperes. When transformers are connected up star fashion, as in Figs. 9 and 11, the current in each transformer winding is the same as that in the line wire to which it is connected, but the e.m.f. between the terminals of each transformer winding is 57.735 per cent of the e.m.f. from wire to wire on the circuit. For example, if the primary e.m.f. from *A* to *B* is 1000 volts, the e.m.f. at the terminals of the left-hand transformer (from *A* to *J*).

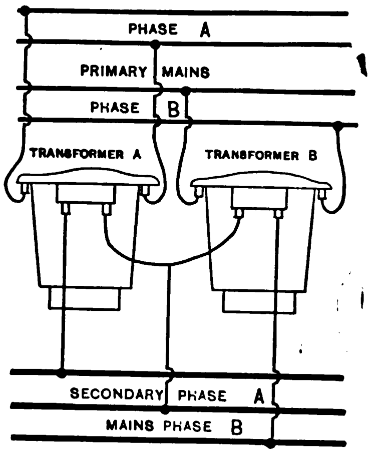

FIG. 7.—TWO-PHASE CONNECTIONS; THREE-WIRE SECONDARY.

will be only 577.35 volts, and the same is true of each of the other transformers if the system is balanced.

These statements apply, of course, to both primary and secondary windings, from which it will become evident that if the three transformers of a three-phase circuit be connected up star fashion at the primaries and delta fashion at the secondaries, the secondary voltage will be lower than if both sides are connected up star fashion. For example, if the transformers are wound for a ratio of 10 to 1 and are connected up with both primaries and secondaries alike, no matter whether it be delta fashion or star fashion, the secondary e.m.f. will be one-tenth of the primary e.m.f.; but if the primaries be connected up star fashion on a 1000-volt circuit and the secondaries be connected up delta fashion, the secondary voltage will be only 57.735 volts instead of 100 volts. The explanation of the difference between the voltage per coil in a delta system and that in a star system is that in the former each winding is connected directly across from wire to wire; whereas in the star system two windings are in series between each pair of line wires. The voltage of each winding is not reduced to one-half, however, because the e.m.fs. are out of phase with each other, being 120, or one-third of a cycle, apart; consequently, instead of having 500 volts at the terminals of each coil in Fig. 9, the voltage is 577.35. The same explanation applies to the current values in a delta system. The current phase between *A* and *B*, in Fig. 8, is 120 removed from that in the winding between *A* and *C*; consequently, the sum of the two currents in the wire, *A*, is 1.732 times the current in each wire; or, to state it the opposite way, the current in each winding is .57735 of the current in the wire, *A*. It will be well for the reader to remember that in all cases e.m.fs. differing in phase when connected in series, combine according to the well-known law of the parallelogram of forces; current differing in phase and connected in parallel combine according to the same law.

Letters on Practical Subjects

Problem in Bell Connections.

To the Editor, American Electrician:

I submit herewith a problem in bell connections, the object being to use the least amount of wire that will produce the desired results. The diagram shows the wiring for an ordinary flat equipment of door bell and door-opener, with an additional bell, *a*, and push-button, *b*. It is desired to put a button, *c*, in the parlor and connect it to ring one of the bells and operate the door-opener, *d*, simultaneously. The kitchen is the only place where the existing wiring is accessible for making connections The battery is in the basement. Ground connections not allowed.

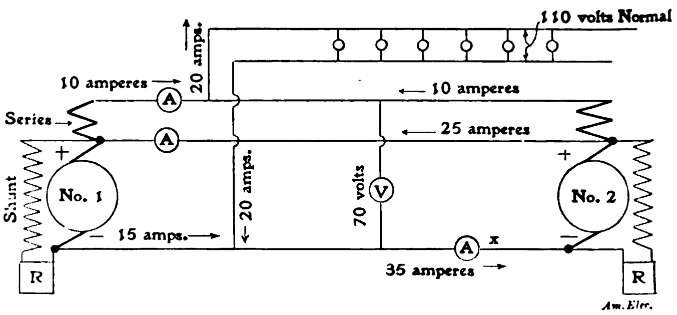
Peculiar Trouble with Generators Operating in Parallel.

To the Editor, American Electrician:

I was recently confronted with a peculiar trouble when operating two generators in parallel. The machines are of the same size and make and are slightly under-compounded. In ordinary operation each machine carries its load of 50 amperes, and the machines divide the load almost equally. The shunt field resistance ordinarily is all cut out. Weakening the shunt field of No. 1 by cutting in some resistance causes it to motor and the voltage drops to 60 or 70 volts, causing the condition shown in the accompanying sketch. By cutting in more resistance the equalizer current increases and the voltage drops still more. When the experiment was tried there were enough lamps in circuit to give a normal load of 25 amperes on each machine, or one-half load on each generator. The current shown by an ammeter placed at *x* did not at any time exceed 50 amperes. Why should the voltage drop with such a slight flow of current? Another peculiar case happened with a motor running under no load and connected to a single generator circuit. The generator



GENERATORS OPERATING IN PARALLEL.

was stopped without the generator or motor switches being opened and the counter e.m.f. of the motor reversed the flow of current and changed the polarity of the generator. In this instance the generator was over-compounded and the shunt field rheostat was probably turned off before the generator was stopped.

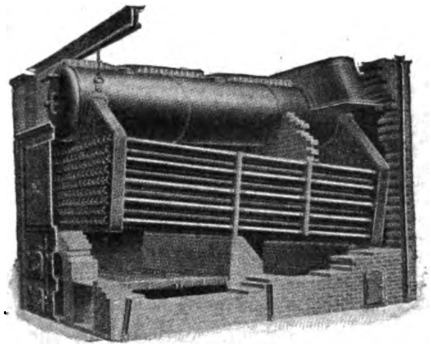
Sprung Tubes in Water-Tube Boilers.

To the Editor, American Electrician:

The writer has had brought to his attention a peculiar state of affairs in connection with a battery of water-tube boilers of a standard make which is considerably puzzling, and for various reasons submits the case to your readers for a solution. The boilers, which are of 125 horse-power each, are fitted with grates about 5 ft. by 5½ ft. and a mixture of 1/3 buckwheat with ⅔ bituminous coal is used for fuel. Feed water is pumped in against 198 lbs. boiler pressure and at a temperature of about 205°, the water being a mixture of condensation from the surface condensers and river water, about .005% of oil being present in the condenser water. The bottom tubes are of No. 9 gauge and the boiler was inspected by a standard insurance company for high pressure when the plant was installed, which was only recently. Upon removing the hand-hole plates for inspection, the bottom row of tubes from the header to the bridge wall immediately over the grates was found curved up about one inch. The tubes do not show traces of oil and seem to be perfectly clean. Could a high fire, due to the coking of the fuel, cause the condition mentioned, or could it be that the boiler had been at some time forced and the circulation was not rapid enough? Why should the tubes curve up and not sag? I should be pleased to get the opinion of your readers on the matter.



WATER-TUBE BOILER.

Simple Three Party-Line Telephone System.

To the Editor, American Electrician:

There are many party-line schemes based on the strength and polarity of current, which require special apparatus not always convenient to obtain. I have devised the following arrangements for a three-party line system which can be applied to any short private or exchange telephone line by adding two strap keys to each instrument. Fig. 1 shows the principle of the arrangement. Telephones *A*, *B* and *C* are connected in series by wires 1, 2 and 3. If *A* should desire to ring *B*, it is obvious that if the wires 1 and 3 are short-circuited while *A* is ringing, only the telephone bells of *A* and *B* would respond. Similarly, *A* could ring *C* only by closing wires 2 and 3, or *C* could ring *A* and *B* and *B* could ring *A* and *C* by short-circuiting the proper wires. If now wires 1 and 2 are made the two wires of a metallic circuit and wire 3 be replaced by a ground, a three-station selective party line results. Fig. 2 explains this more clearly. This scheme, while very simple, has the defect that if the button is not kept pressed while the generator handle is being turned all three stations will be rung up. By wiring the telephone as shown in Fig. 3, this defect will be obviated, it being necessary to break the circuit of the lines you do not want in order to ring the proper station. Fig. 4 shows the system applied to bridging phones. The system can be further extended to four phones by using three wires as shown in Figs. 5 and 6, but beyond this the signalling apparatus becomes too complicated. For short lines no trouble is experienced in talking through the one or two 80-ohm ringers. If bridging phones are used on long lines, it might become necessary to place a set of ringer coils on the dead-ends of the lines at the terminal stations in order to balance the line, the center station, of course, being across the line.

Queries and Answers

IMPORTANT.—No attention will be given to any inquiry which does not give the full name and address of the inquirer.

Is there any specific acknowledged limit beyond which it is not commercially profitable to distribute direct current? J. K. I.

There is no hard-and-fast limit; but it is usually considered preferable to use alternating current when the radius of distribution exceeds 2½ miles.

Where should equalizer-switch pedestals be located? A. E. E.

At points as near the respective machines as practicable, keeping in mind that the equalizing conductor should be laid in as nearly a dead straight line, from end to end, as possible.

Where can I obtain instruction in the design and winding of motors which will enable an electrical machinist or other skilled worker to build a machine properly without understanding the science of dynamo design? F. C. S.

A series of articles of this character begins in this number; see page 538.

How many cells of battery are required to maintain four 20-volt lamps taking ¼ ampere each? (2) How should the outfit be connected up? O. DeC.

About twenty cells of primary battery or ten cells of storage battery. (2) Connect the battery cells in series and the lamps in parallel.

Please give data for the construction of an induction coil to give a 2½ or 3-inch spark. J. H. B.

Core of No. 22 iron wires 10 inches long, bundled to 1⅛ inches diameter. Primary winding, 2 layers of No. 13 wire, covering 9 inches of the core. Secondary winding, 4 lbs. No. 36 double silk-covered wire, wound to cover 8½ inches of the primary coil length. Condenser, 60 tinfoil sheets, each 6 ins. x 8 ins.; dielectric, heavy bond paper, 7 ins. x 10 ins.

Under ordinary central station conditions is a simple condensing engine ever preferable to a compound condensing engine? (2) Is there any preference between a vertical and a horizontal engine for central station service? K. F. U.

Not in stations of appreciable magnitude. (2) Each has several advantages over the other; local conditions almost always determine the choice. The vertical type shows much less cylinder wear and less tendency to rack foundations; the horizontal type is much more accessible and easier to dismantle, and so on.

A 50-light T.-H. arc light dynamo supplying seventeen lamps runs extremely hot; a resistance in parallel with the field windings relieves the heating, but it is not convenient to use it regularly. What causes the heating and how can it be remedied? H. S. B.

The heating is due to the fact that at light loads the position of the brushes is such that the armature coils are short-circuited during a considerable proportion of each revolution. It can be cured only by keeping a resistance in shunt to the field winding, so that the regulator will adjust the brushes to a better position.

How far apart should the wires of a 440-volt, three-phase circuit be spaced for best results? (2) What changes in the windings of the three-phase synchronizer described in the May number would be necessary to make it applicable to 440-volt machines? C. W. C.

Put all three in a single conduit, if indoors; if it is an outdoor line, put the wires 6 inches apart. (2) The primary coils of the three-phase transformer should be wound with 2238 turns each of No. 27 double silk covered wire; the primary coil of the single-phase transformer should contain 1580 turns of No. 29 double silk covered wire. The secondary coils require no changes.

What would be the dimensions, etc., of a condenser of one microfarad capacity? (2) What is the "S. K. C. system" and what do the letters mean? A. R. E.

The data depend on the kind of dielectric used. If you use ordinary glass sheets 1/16 inch thick, 18,000 square inches of tinfoil (counting one side only of each sheet) will be necessary. If the tinfoil sheets were 20x12½ inches, you would require 72 sheets. The glass panes must be considerably larger than the tinfoil sheets, say, 14x24 inches. (2) It is the system of apparatus developed by Messrs. Wm. Stanley, John Kelly and C. C. Chesney and built by the Stanley Electric Mfg. Company.

Several of our armatures have cross-connections between different points of the windings, said to be equalizers. The machines work as well without them as with them if the brushes are in good condition. What are they for? (2) Can a magnet be made to work on alternating current as well as on direct? H. W. W.

The connections are to make sure that points of the armature which should be at equal potential shall be so regardless of lack of symmetry in the field magnetization or the brush contact resistance. Without them, such lack of symmetry, if it should occur, will cause differences of potential between these points which will send heavy local currents through the armature winding. (2) Yes; but a magnet for alternating current is of greatly different design and construction from one built for direct current.

Will a four-pole, direct-current dynamo work as well with four shunt field-magnet coils and two series field-magnet coils as if the series winding were divided among all four poles equally? (2) What is the lowest resistance that can be connected across the terminals of a constant-potential dynamo without injuring the machine? W. C. A.

If the machine has a two-path armature winding it will probably work as well, but if not, it will be better to use four series coils. (2) A resistance of the number of ohms equal to the voltage of the machine divided by its rated current-carrying capacity. Thus, a 110-volt 50-ampere dynamo may have a resistance of 110 ÷ 50 = 2.2 ohms connected to its brushes without damage; any lower resistance would produce overheating if kept connected up for a considerable length of time, such as two or three hours.

What is the resistance of the ground between two copper plates each 12 inches square buried one mile apart? (2) Does the resistance vary inversely as the area of the plates and directly as the distance between them? (3) Do the turns of wire farthest away from the core in a magnet coil have the same effect on the core as the turns nearest the core? (4) Does it make any difference whether the primary winding of an induction coil is inside or outside of the secondary winding? C. M. F.

It varies enormously; there is no formula that will give even the roughest approximation. (2) The size of the plate affects the resistance of contact between it and the surrounding earth, but does not affect the resistance of the path through the earth, of course. The resistance of contact, however, is vastly higher than that of the earth itself. Consequently the distance between the plates has less effect on the total resistance of the circuit than the size of the plate and character of the contact with the earth. (3) Practically, yes. (4) So far as the mutual induction between the two windings is concerned, no. There are disadvantages in practice, however, which make such an arrangement undesirable.

Why will not a shunt-wound dynamo build up in the direction opposite to normal when the connections between the brushes and field winding are reversed? (2) What is the origin of the formula

$$\frac{16{,}039\ H.P.\ D}{E\ eff.\ V} = d^2$$

giving the size of wire for motor wiring. *H.P.* is the horse-power of the motor, *eff.* is its efficiency, *D* is the distance, *E* is the e.m.f. at the motor and *V* is the drop in volts in the line? J. B. D.

Because the e.m.f. generated by the residual magnetism tends to magnetize the field in opposition to the magnetism generating it; in other words, the machine kills its own residual magnetism. (2) It is derived from the formula:

$$\frac{21.5\ I\ D}{d^2} = V,$$

in which I is the current. The resistance of copper wire is taken at 10¾ ohms per foot for one circular mil cross-section; there are two wires, so that the length of wire is twice the distance, D, and the resistance per foot of line is 21.5 ohms for unit cross-section. Dividing 21.5 by the cross-section of the wire ($21.5 \div d^2$) gives the resistance per foot of line; multiplying this by the distance gives total resistance, and multiplying this by the current gives the drop, according to Ohm's law. Now, the current taken by a motor is equal to the watts divided by the voltage, E, and the watts are equal to the horse-power multiplied by 746 and divided by the efficiency of the motor expressed decimally; therefore, $I = 746 \times h.p. \div E \times efficiency$, which changes the fundamental formula to

$$\frac{21.5 \times 746 \times h.p. \times D}{E \times efficiency \times d^2} = V.$$

Multiplying 21.5 by 746 and transposing d^2 and V will give the formula you quote.

HAMILTON-HOLZWARTH STEAM TURBINE.

The application of the steam turbine as a prime mover for driving electric generators has in the last few years been brought into prominence in steam plant construction, insomuch so that it bids fair to become a formidable competitor of the reciprocating engine. Some of the reciprocating engine builders have therefore taken up the manufacture of turbines, and one of the latest to make its appearance is the Hamilton-Holzwarth steam turbine built by The Hooven-Owens-Rentschler Company, of Hamilton, Ohio. These turbines, like those of the Parsons type, have a plurality of stationary discs and running wheels, the discs and wheels having vanes all around their circumference. It differs from the Parson, however, in that expansion takes place only in the stationary blades and not in both the blades and running wheels. The radial length of the vanes of the stationary blades is increased to correspond to the volume to which the steam has expanded. The number of wheels and vanes in the turbine is also considerably less than those of the Parsons type. The balance pistons are omitted because the axial thrust of the running wheel shaft is said to be so small that it can easily be taken up by a thrust ball-bearing.

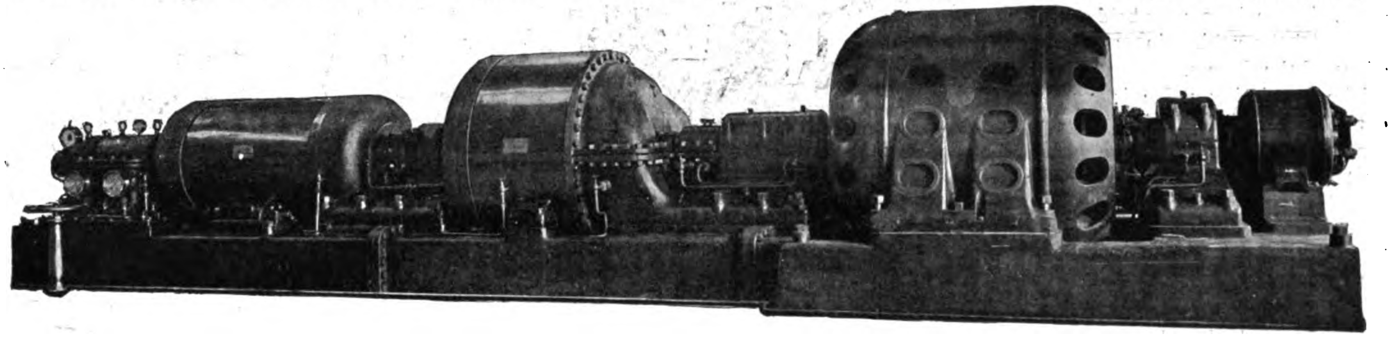

FIG. 1.—HAMILTON-HOLZWARTH STEAM TURBINE.

For units of 750 kilowatts and upward the rotating body is divided into two parts, a high and a low-pressure turbine; smaller units are built in one turbine casing. The turbine casing and pedestals for the bearings in the generator are placed upon a bed plate of the box pattern, and all steam, oil and water piping, including the steam inlet, regulating and by-pass valves, are within and below the bed plate. After passing through the steam separator, the steam passes through the main inlet valve which has an extended stem connected with its floor stand and a hand-wheel located on the floor close to the high-pressure end of the turbine. It then passes through the regulating valve and from there through a curved pipe to the head of the high-pressure turbine. From the ring channel of this head the steam flows through the first set of stationary vanes, which changes its direction and imparts the necessary velocity. From here the steam flows in a full cylindrical belt interrupted only by the vanes of the first running wheel, and from here to the following stationary discs, and so on. From the last running wheel the steam is led through receiver pipes to the front head of the low-pressure casing, or if there is only one casing, immediately to the condenser. The condenser, which may be either of the jet or surface type, is placed as near as possible to the exhaust opening.

In the low-pressure casing the steam is distributed in the same manner as in the high-pressure turbine. The low-pressure front head, however, has an additional nozzle through which live steam enters for use in case of overload. The design is such that this steam, which is controlled by the governor, exerts no back pressure to the steam from the high-pressure turbine. On the contrary, it is said to work like an injector, sucking the low-pressure steam through the stationary vanes of the low-pressure turbine. The first stationary disc of the low-pressure turbine has guide vanes all around its circumference so that the steam enters in a full cylindrical belt interrupted only by the guide vanes. These vanes have a varying radial height increasing in the direction in which the steam flows. This allows the steam to expand within the stationary vanes. At the same time, the vanes are said to guide the steam under such a small angle that the force with which the steam impinges on the next following running wheel is as effective as possible.

The hub of the running wheel runs in the bore of the stationary discs, and the manufacturers claim that inasmuch as the stationary discs are extended nearly to the shaft of the turbine the clearance, and hence the leakage losses, have been restricted to a minimum practical limit. The stationary discs are located in grooves in the turbine casings, which are horizontally split, and so designed that with the smallest weight the strains in the material, due to the static steam pressure, do not exceed the limits usually allowed in ordinary practice. The vanes are of drop-forged steel, milled and located in a groove on the outside periphery of the discs. They are fastened to the discs by rivets, after which the discs and vanes are ground on their outside edges. A tough steel ring is then shrunk on the outside periphery of the vanes and steam channels.

The running wheels are built with cast steel hubs, and steel discs are riveted to both sides of this hub and form a circumferential ring space in which the vanes are held by means of rivets. The vanes are milled on both edges on the influx and efflux sides of the wheel, and in order to reduce their weight as much as possible, as well as their stress on the rivets, they are made hollow lune shape. Steel clips with welded channels are pressed on one end, after which they are milled so that they fit on the running wheels, which are then carefully balanced.

The bearings are the only part of the turbine proper, with the exception of the governor regulating mechanism and pump, where metal comes in contact with metal, and here the running parts are amply supplied with oil. The pedestals and caps are designed in such a mamner that the oil inlet and outlet are placed close together on the side of the pedestal so that no piping has to be deranged to take out the bushings. The oil flows to the bottom bushing under a slight pressure and then with the rotating shaft, being finally taken off in the cap. From here it flows back to the oil outlet in the pedestal. With the thrust ball bearing on the thrust side of the turbine, the manufacturers claim that it is possible to move the whole shaft in an axial direction and to change the position of the running wheel to that required by the stationary discs. Flexible couplings are used between the high-pressure and the low-pressure shafts and between the low-pressure shaft and generator shaft, so that each shaft can be fixed and located without affecting the location of the others.

Each half of the flexible coupling consists of a disc screwed upon the shaft and secured to it by means of a key. Near the outer circumference these discs have steel laminations connected to brushes and firmly secured to the coupling disc. The brushes of one disc fit between the corresponding brushes of the other disc, so that the several pairs of brushes distributed over the circumference will always lean together in whatever direction the coupling may be turned. The spring of the laminations is said to insure the flexibility needed.

At the four places where the shaft enters the steam chambers of the casing a stuffing box of special design with interchangeable parts is used. These boxes contain no half rings and the design is based on the fact that a shaft revolving in a sufficiently long box with small clearance throttles the steam which tries to escape along the shaft. In order to avoid a long box, the builders make a practical use of the idea embodied in the telescope. A ring fastened to the shaft and revolving with it extends axially into a deep groove of another ring which does not revolve. By means of this annular space, half rings pressing against collars on the shaft are avoided. The stationary curved ring presses against the adjoining bearing bushings, and the space between this ring is connected with a drain pipe on the pressure side and a waterpipe on the vacuum side. By this means the manufacturers claim that it is impossible for steam to leak along the shaft.

The governor is of the spring and weight type and is directly driven by the turbine shaft. Two discs, key-seated to the shaft, drive by means of rollers two weights sliding along a cross-bar placed at right angles through the shaft and pressing two springs against two nuts on the same cross-bar. Every outside movement of the weights caused by the increase or decrease of speed is transmitted by means of levers to a sleeve actuating the regulating mechanism. The governor is closed on both sides by the discs and by a ring secured by concentric recesses to the disc. Thrust ball-bearings and frictionless roller-bearings are used to decrease the friction between the governor and the regulating mechanism, and the shaft is coupled to the sleeve with a special coupling to avoid the friction due to the shifting of the governor sleeve along the key which transmits the turning movement of the shaft. On both ends of the sleeve two fingers extend into the corresponding spaces on the shaft. These fingers are held apart by means of steel balls rolling in grooves cut in the edges of the fingers.

The regulating valve is connected by a curved pipe with the high-pressure front head on one side and with the inlet valve on the other. The valve is of the double-seated poppet type, the valve seats being of tough cast steel and the valve body of cast iron. Immediately below the regulating valve, and forming a part of it in one steam chamber, is located the by-pass regulating valve. This valve controls the quantity of steam flowing directly to the by-pass nozzles in the low-pressure front head and is also of the double-seated poppet type. The main regulating valve is not actuated directly by the governor, but by means of the regulating mechanism. The principal idea of the regulating mechanism is as follows:

The stem of the regulating valve is driven by means of bevel gears by a shaft which is supported in frictionless roller bearings. On this shaft there is a friction wheel which the governor can slide across the face of a friction disc (which is continually revolving) by means of its sleeve and bell crank lever. The continually revolving friction disc is keyed to a solid shaft which is driven by a coupling from a hollow shaft. This hollow shaft is driven by means of worm gear by the turbine shaft. The solid shaft with the always revolving friction disc can be slightly shifted by the governor sleeve, so that the two friction discs come into contact when the sleeve moves; that is, when the angular velocity changes. If this change is relatively great, the sleeve will draw the periodically revolving friction disc far from the center of the always revolving one, and this disc will drive quickly the stem of the regulating valve and regulate the steam flow.

As soon as the angular velocity falls below a certain percentage of the normal speed the driving friction disc is drawn back by the governor, the regulating valve remains open and the whole regulating mechanism rests or stops, though the shaft is still running. This is an important feature of the regulating mechanism on account of the fact that the turbine continues to run for ten to twenty minutes after the main inlet valve has been closed.

The governor shuts down the whole turbine as soon as the angular velocity reaches a point 2½ per cent. higher than normal. Even if any accident should happen to the governor, due to imperfect material, breaking or weakening of the springs, etc., the only thing which, the builders say, would result from this accident would be a shutdown of the turbine, hence the omission of an auxiliary governor for safety, as required when other types of governors are furnished.

In order to change the speed of the turbine while running, which might be necessary in order to run the turbine parallel with another prime mover, a spring balance attached to the bell crank lever of the regulating mechanism is provided. The hand wheel of this spring balance is outside of the pedestal for regulating the mechanism, near the tachometer and floor stand and hand wheel. With this spring balance the normal speed of the turbine may be changed 5 per cent. either way.

All bearings of the entire turbo-generator are fed with a sufficient quantity of oil to insure cool running. The oil flows from an oil tank of large capacity (a part of the bed plate being used for this purpose) to the oil pump, which is driven by means of worm gearing by the turbine itself. From here the oil is forced through the bearings and flows back to the oil tank. Here it is cleaned by flowing through a strainer and has sufficient time to radiate part of the heat to the walls of the bed plate. The pressure pipe to each bearing can be closed by a valve so that one can easily regulate and control the flow of oil to the different bearings. As all revolving parts of the turbine are enclosed and the principal part of the regulating mechanism operates in a bath of oil, the whole turbine is lubricated automatically.

◆◆◆

A NEW FORM OF OIL SWITCH.

The use of the oil switch is becoming more prevalent each year, especially on high-voltage work wherein its principal field lies. Prominent among the various types are those operating with a horizontal break. In this form the contacts are usually located near the surface of the oil and the arc when drawn is carried upward by the generated gases, increasing in length and breaking just below the surface of the oil. Fig. 1 herewith shows the form M oil switch brought out by the Stanley Electric Manufacturing Company, Pittsfield, Mass. The switch is of the horizontal-break form and is furnished complete with oil and tank. The breaking distance in the lower voltages corresponds to standard practice, but in the higher voltages is increased by multiplying the number of breaks. Both the fixed and moving contacts are disc-shaped with round edges and are interchangeable. When the switch is opened the arcing is said to take place between portions of these rounded edges rather than over the flat portions which form the contact surfaces. From the back of each disc a threaded projection extends which in the case of the fixed contacts screws directly into the end of a hollow stud. In the moving contacts, however, two nuts secure each to a connection strip. This construction facilitates removal and the expense of replacing the discs is trifling. Portions of the rounded edges after long use become damaged by the arc and new portions can be easily brought into play by giving the discs a partial turn. This prolongs the life of the switch materially. The fixed contact discs are held against the lower ends of the insulators by hollow studs into which they screw, and the lead wires are soldered into the top of these studs. By means of ball joints the moving contact discs are mounted upon the carriers which are rigidly attached to the driving rod. The discs are said to be self-aligning in regard to the fixed discs against which, when the switch is closed, they are pressed by strong coil springs. All parts requiring renewal can be removed and replaced with an ordinary wrench and screw-driver. The switches may be used in connection with over-load time limit or reverse current relays. They are built for 2500 and 6600 volts in 2, 3 and 4-pole single or double-throw, with or without enclosed fuses and holders or over-load attachment.

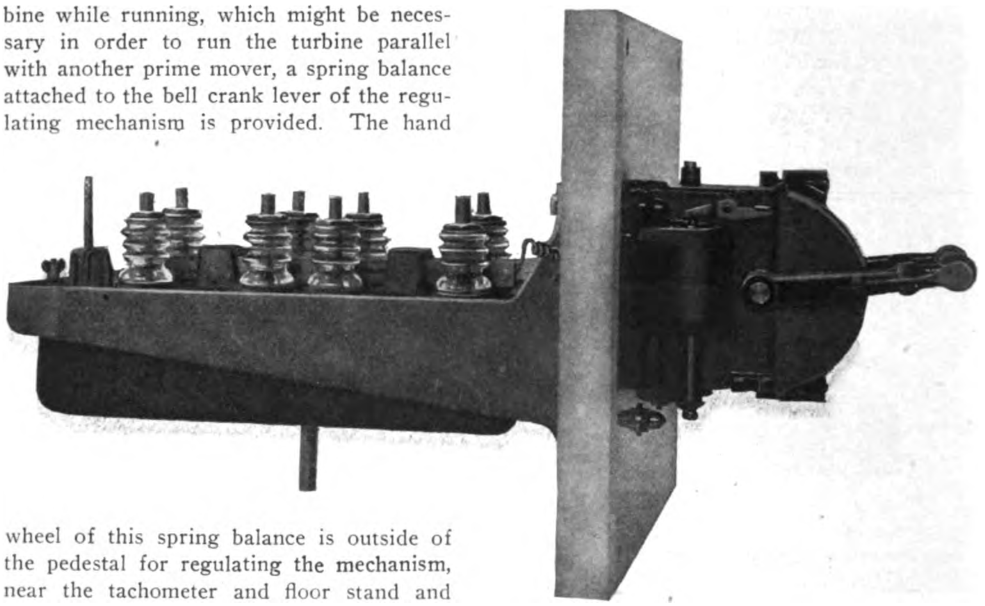

FIG. 1.—STANLEY FORM M OIL SWITCH.

New Apparatus and Appliances

A PUSH-BUTTON PENDANT SWITCH.

The Trumbull Electric Manufacturing Company, of Plainville, Conn., has just brought out a new pendant switch shown by Fig. 1 herewith. The switch is neat in appearance and is finished in nickel or polished brass. It is guaranteed to operate successfully at its rated capacity (10 amperes and 125 volts) 10,000 times without injury. The switch is a snap switch of special design. The mechanism is somewhat similar to that of the push switch, excepting that it is arranged to operate by means of only one button. The switch proper is of brass, each end of the switch blade being carried by the rotation of the switch between a pair of spring-copper clips. The mechanism is completely housed in porcelain and ample space is provided for making connections.

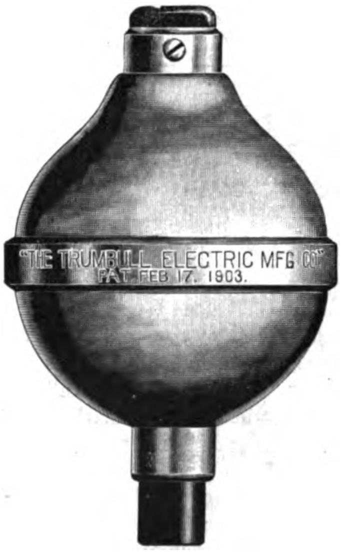

FIG. 1.—PUSH BUTTON PENDANT SWITCH.

VOLTMETER AND GROUND DETECTOR SWITCH.

Figs. 2 and 3 show front and rear views of style H voltmeter and ground detector switch made by the J. Lang Electric Company, of Chicago, Ill. The switch is built only for rear board mounting, and in sizes from 3 to 12 ins. inclusive. It is said to be compact, durable and without troublesome, coiled springs, and the contact surfaces are claimed to be ample and self-cleaning. A feature of the switch are the fuse terminals in each leg of the circuit, which are a self-contained part of the switch. It is not, therefore, necessary to place a cluster of fuse blocks on the board in addition to the voltmeter switch. Link or enclosed fuses may be used.

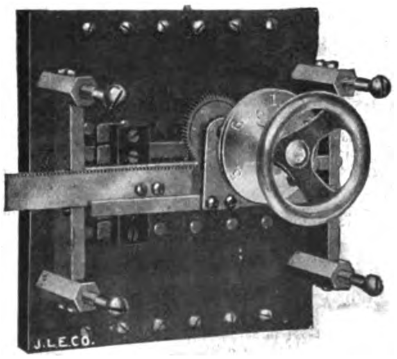

FIG. 2.—FRONT OF VOLTMETER SWITCH.

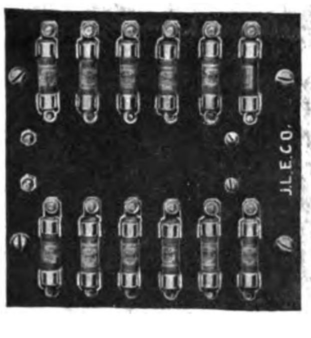

FIG. 3.—REAR OF VOLTMETER SWITCH.

"STANDARD" STATION PHOTOMETER.

Fig. 4 herewith shows the "Standard" station photometer made by the Dwyer Machine Company, of Lynn, Mass. This instrument, it is claimed, possesses many practical features as a result of every day experience, and all the parts are made of either iron or brass. The shadow car runs on a machine-planed track and is operated by a hand wheel. The lamp-revolving mechanism is started and stopped by a foot-operated clutch. Referring to the illustration, the right hand end is intended for the lamp used as a standard, and the left hand end for the lamps being measured. To set the instrument for work, a petty standard is made by placing a lamp taken from those being measured or a lamp kept for the purpose, in the right hand socket, and a calibrated standard in the left hand socket, care being taken to point the arrow which is usually affixed to such lamps along the axis of the instrument. The primary rheostat, which is of the sliding type, is set to its maximum resistance, the current is switched on and then adjusted until the voltmeter indicates the potential of the calibrated standard. When the voltmeter indicates this potential, it is clear that the lamp is giving standard candle power. The petty standard is now set to this one by balancing the shadow car between them, or if this point proves to be far removed from the center of the instrument, by adjusting the secondary rheostat until the car can be balanced sufficiently near the center to be convenient for the operator to work. The calibrated standard can then be removed and the instrument is ready for work. It will be noted that the calibrated standard is used only to set the petty standard by. This saves this lamp and with ordinary care it will last for years. A lamp to be measured is now placed in the socket from which the calibrated lamp was removed, the foot treadle is pressed, causing the lamp to revolve, the car is balanced and the candle power is read by the indication of the pointer attached to the car and also from an auxiliary scale directly in front of the operator placing the lamps in position and removing same. The reading is further facilitated by the light from a lamp which lights when a lamp is removed.

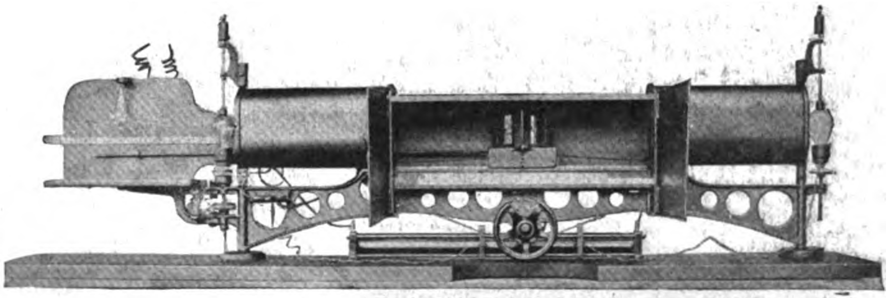

FIG. 4.—"STANDARD" STATION PHOTOMETER.

FABER BLOW-OFF VALVE.

Fig. 5 herewith shows the Faber blow-off valve, manufactured by the Liberty Manufacturing Company, of Pittsburg, Pa. In this valve a jet of steam cleans both the seat and disc after the water is shut off, but before final closing. This will be made clear by reference to the illustration. Surrounding the seat, *A*, is a chamber, *B*, into which steam is admitted at full boiler pressure through a half-inch connection leading from the steam main. The discharge takes place in the direction indicated by the arrow, and when the disc, *D*, is in the position shown, the water is practically shut off. From this point the disc moves ¾ inch before closing on the seat, and during that time steam escapes from the chamber, *B*, through the narrow slot, *E*, all around the seat. The result of this, the manufacturer claims, is the sweeping of any scale from both the seat and disc, so that when the valve closes

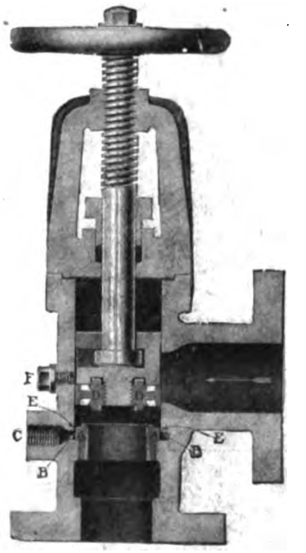

FIG. 5.—FABER BLOW-OFF VALVE.

these are clean. The connection, *C*, should be provided with a valve which should be left open all the time except when the boiler is out of service.

THE "SEMI-DIMOND" TOOL.

The emery wheel dresser shown herewith and manufactured by the International Specialty Company, of Detroit, Mich., is designed to take the place of the expensive black diamond. This is claimed to be a most efficient tool for the purpose, and the maker says will do the work of truing and shaping emery wheels in as satisfactory a manner as the diamond dresser. The "Semi-Dimond" dresser is a steel tube filled with hard abrasive, which presents new cutting edges the entire length of the tube and as long as it lasts. The dresser is not recommended for water grinders or very hard wheels, although it can be used on these if necessary. Its efficiency is best demonstrated on grades up to medium hard.

FIG. 6.—"SEMI-DIMOND" TOOL.

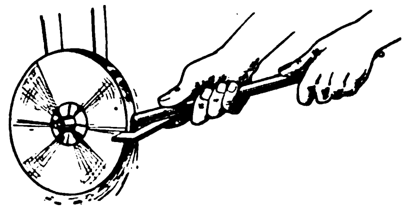

FIG. 7.—EMERY WHEEL DRESSER.

A NEW WIRE COUPLING.

A device for coupling stranded wires together, known as the Dossert type B joint, has just been placed on the market by Dossert & Company, of New York. Exceptional claims are made for it as superior in convenience, cost, conductivity and durability to the soldered joint. The joint is made of seven parts, six of which are in pairs. They consist of an inside ring, an outside ring and a compression nut. The remaining part carries nipples, on which compression nuts carrying the wire properly prepared are screwed. These nipples may be in the form of crosses or tees or may be cast on to bus-bars or fittings of any kind, and will enable the cable to be fastened securely thereto. The joint is made in the following way: The end of the cable is stripped the length of the compression nut and cleaned. The compression nut is then slipped upon the cable together with a small outside ring. The outer strands of the cable are then stripped and an inside ring is driven around the inner core of strands with a steel tube provided for the purpose. The outer strands are then molded back as nearly as may be to their original position. This can be done with a screw-driver, but a steel tube provided for the purpose is more convenient. The application of a joint of this character in the manner shown in Fig. 8 requires only seven minutes on a 1,000,000-circ. mil. cable. Figs. 9 and 10, being actual pictures of the joint itself, display its construction to better advantage. In Fig. 10 strands are cut away so as to show the inside ring. Fig. 11 displays this joint and its alternative soldered joint and underneath parts of the new joint. The makers of this joint have subjected it to tests before putting it upon the market. On millivoltmeter test the joint is claimed to show a conductivity greater than that of an equal length of wire. The mechanical strength of the joint was tested in a tension machine, where it developed more than two-thirds of the strength of the cable it united. The makers guarantee the joint to stand 50 per cent of the strength of the cable, which they claim is superior to the soldered joint on account of the amalgamating and deteriorating effect of the solder on the copper. It is also asserted that the soldered joint well made required a skilled man, while an ordinary helper has no difficulty in making the Dossert joint. The new joint wastes no cable and involves no other expense than its own cost and the time of putting it on.

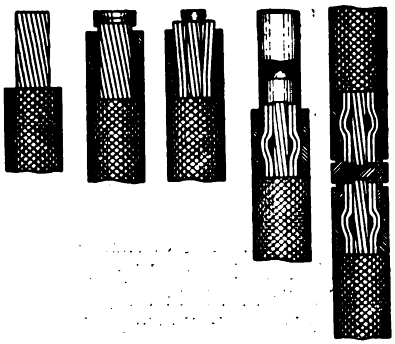

FIG. 8.—MANNER OF ASSEMBLING DOSSERT JOINT.

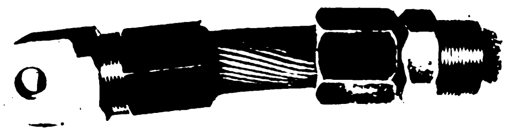

FIG. 9.—VIEW OF COMPLETE JOINT.

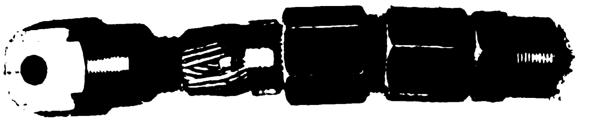

FIG. 10.—A 1,000,000-CIRC. MIL JOINT WITH STRANDS CUT AWAY.

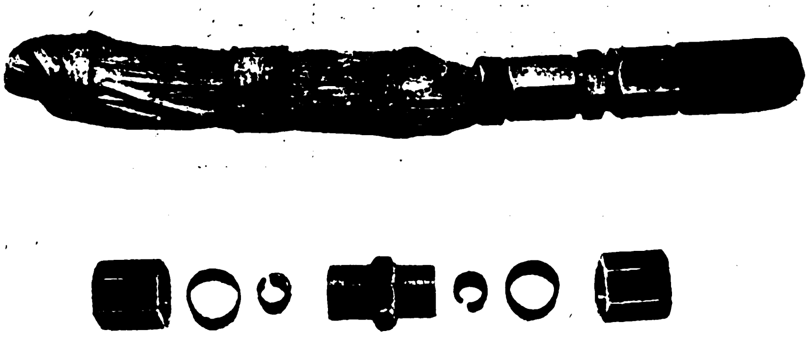

FIG. 11.—SOLDERED AND COUPLED JOINT WITH PARTS OF LATTER.

FORT WAYNE SERIES ALTERNATING SYSTEM OF STREET ARC LIGHTING.

This system, in common with other alternating series arc lighting systems, consists of a combination of a constant current regulator and a number of arc lamps connected in series, and includes the use of a "Wood" regulator which is mechanically different from any others on the market, and Form C "Wood" arc lamps specially designed for this service.

The automatic regulator consists of a W-shaped, laminated iron core and a reactance coil surrounding the center leg of the iron core. The coil and core are hung on levers supported on knife edges in such manner that the coil and core counterbalance each other and are both movable.

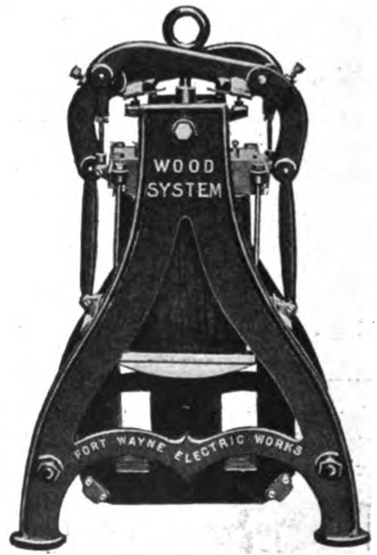

FIG. 1.—WOOD REGULATOR.

Through the lever system the coil forms a counterbalance to the heavy core and the levers are so arranged that of the total travel the coil moves over the greater portion of the distance. It is required to lift the core only through a short distance. The regulator coil is connected in series with the arc lamp circuit, to which it furnishes a constant current suitable for the arc lamps on the line. The regulation is automatic.

Any change in the resistance of the arc lamp circuit tends to produce a corresponding change in the current in the circuit, since the line voltage remains constant. But any change in the current changes the relative position of the core and coil, an increasing current bringing them closer together, a decreasing current allowing them to move farther apart.

As the core enters the coil when they approach each other, due to an increase in current, the additional reactance caused by the magnetic condition thus created serves to counteract the decreasing resistance of the line and secures such an impedance that the current remains intact.

Any decrease in the load tends to increase the current and draws the coil and core together, thus increasing impedance in the circuit, while any increase in the load tends to decrease the current and allows the core and coil to separate, thus decreasing impedance in the circuit. The result is that the current is maintained at its normal value automatically. So perfect, it is claimed, are the mechanical construction and electrical proportions of the regulator that the load may be reduced gradually from full load to no load until the regulator is directly across the line in short circuit without causing any marked change in the current. The load may also, it is said, be changed from full load to short circuit with but momentary current variation. This insures perfect protection to the system against short circuits due to failure of insulation of the outside lighting circuit.

When this regulator is intended for use on a small system of 25 lights or less the lighting system may be connected directly to the machine circuit without the use of transformers. When, however, it is necessary to install this series arc system on a machine supplying other circuits, a transformer is recommended. This transformer is connected between the machine and the series arc regulator circuit, insuring perfect separation of its circuit from any others supplied from the same machine.

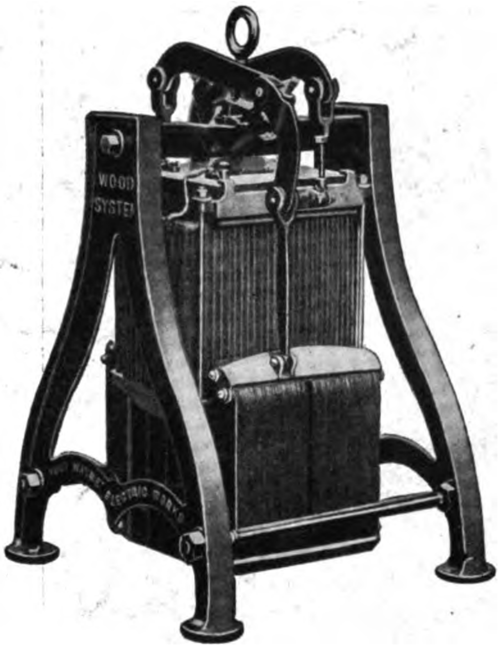

FIG. 2.—WOOD REGULATOR.

Transformers for this use are furnished with one-to-one ratio, or, if higher voltages are required, with the proper ratio to obtain the desired voltage for the arc circuit. It is frequently necessary in installing arc lighting systems to consider extensions of the system to meet the growth of the community. The Fort Wayne series alternating system is designed to take care of extensions and at the same time operate efficiently with the initial load. This is done by installing a regulator large enough to meet the maximum future demands and a transformer furnishing proper voltage to economically operate the regulator with this partial initial load. This lower voltage is obtained from a series of transformer secondary taps, by means of which the arc circuit voltage may be varied from 50 per cent of full voltage up to maximum secondary voltage in steps of such value that the circuit will always be working at approximately full load efficiency. This method of transformation will allow a lighting plant to practically double its series arc lighting output without any increase in the regulating system or transformer, simply by changing the connections on the secondary taps of the transformer, and at all times insures the highest economy and maximum power factor in the regulator circuit.

Figs. 1 and 2 show the "Wood" regulator on a stand for station installation. The knife edges are mounted on the casting supported on two A frames between which the regulator is suspended. The joints in the levers furnish means for adjusting the regulator for the proper current.

SOME EXHIBITS AT THE ST. LOUIS EXPOSITION.

THE GENERAL ELECTRIC COMPANY'S exhibit has been carefully selected, only a few examples of this company's most representative work have been shown. One of the first striking features at its space in Electricity Building is the full-sized model of the 10,000-h.p. vertical shaft generator, as built for the large Canadian power plant at Niagara Falls. The model represents the stationary armature of the machines resting on a concrete base. Inside there is a small circular room, where are photographs of the Niagara Falls electric installations of the General Electric Company. This room also serves to show lighting effects with the three different types of lamp offered by the General Electric Company, namely, the "Meridian" incandescent with prismatic reflector, the enclosed arc with concentric diffuser, and the orthochrome mercury vapor arc lamp, which is a lamp combining the light of the mercury vapor arc and incandescent filament in one lamp.

The Steinmetz mercury vapor arc lamps are exhibited for the first time, and the central tower of the exhibit is surrounded by a circle of these mercury vapor tubes. The tubes of the lamps shown in this exhibit are 16 ins. long by 1 in. in diameter. The current taken by a tube in operation is 3½ amperes operating on a direct-current circuit of 125 volts. The excess voltage above the 65 required by the lamp is taken by a steadying resistance. In the type of lamp known as the monochrome the energy used in this steadying resistance is wasted. In the orthochrome mercury vapor lamp three incandescent lamps in multiple are used as a steadying resistance and placed alongside the mercury vapor tube. The tube and incandescent lamps are all enclosed in a Holophane globe. The incandescent lamps serve to supply some of the red rays, which are entirely lacking in the mercury vapor lamp. The new luminous arc lamp using magnetite instead of carbon can also be seen in this exhibit.

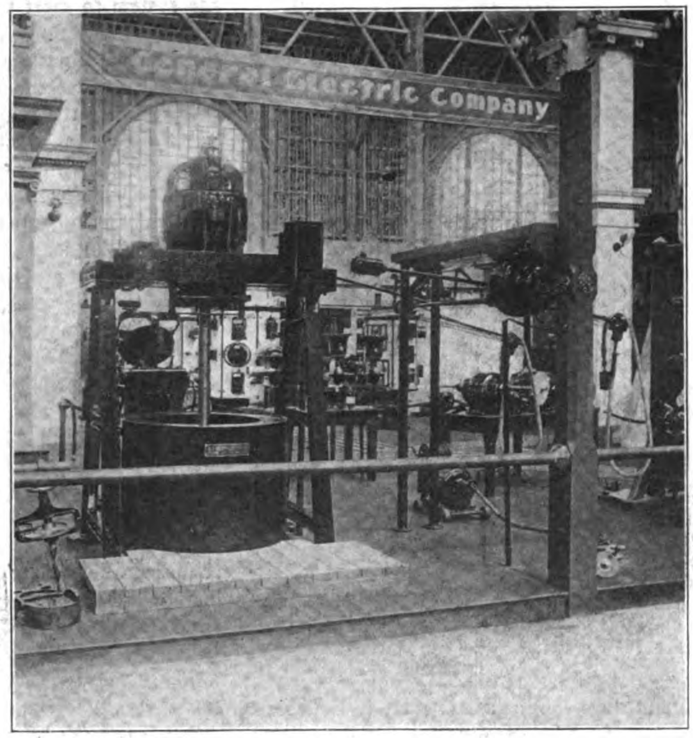
Close to the model of the largest generator ever built is one of the largest oil switches yet constructed, to break a 60,000-volt circuit. Another large piece of apparatus is a 2333-kw. transformer, built to operate with a 2300-volt low-tension and 55,000-volt high-tension voltage. This is one to be used in the Spokane (Wash.) transmission. Two coils of this transformer are shown outside the transformer to illustrate the method of construction. One of these is partially completed, and the other completed. The principle of air-cooled transformers is shown by a 250-kw. transformer of this type mounted over an air chamber, the air pressure in the chamber forcing the air through the transformer. There are also type H oil-cooled transformers.

In the railway portion of the exhibit the Sprague-General Electric multiple-unit train control system, as perfected for the Interborough Rapid Transit Company, of New York, is shown, with car bottom elevated for convenient inspection.

Five different types of railway controllers are shown. A type P 14 air compressor supplies air for cleaning machinery about the exhibit. The General Electric Company's straight air brake system for electric cars is shown for the first time. The application of induction motors to cotton mill driving is illustrated by a 100-h.p. induction motor suspended overhead and belted to four lines of shafting, two belts being run from each end of the motor shaft. In connection with this is an improved starting switch with a curve-drawing wattmeter. The application of electric motors to hoisting is shown by a double-drum Lidgerwood machine hoist electric motor and controller.

A 7-ton mining locomotive is equipped with a cable reel which automatically winds as the locomotive advances or backs up. This new cable relay allows electric locomotives to be run into new portions of the mine where trolley wires have not been installed, and at the same time does not permit the cable to become tangled up or run over by the locomotive. The cable drum contains 700 ft. of cable, and the locomotive automatically winds this up.

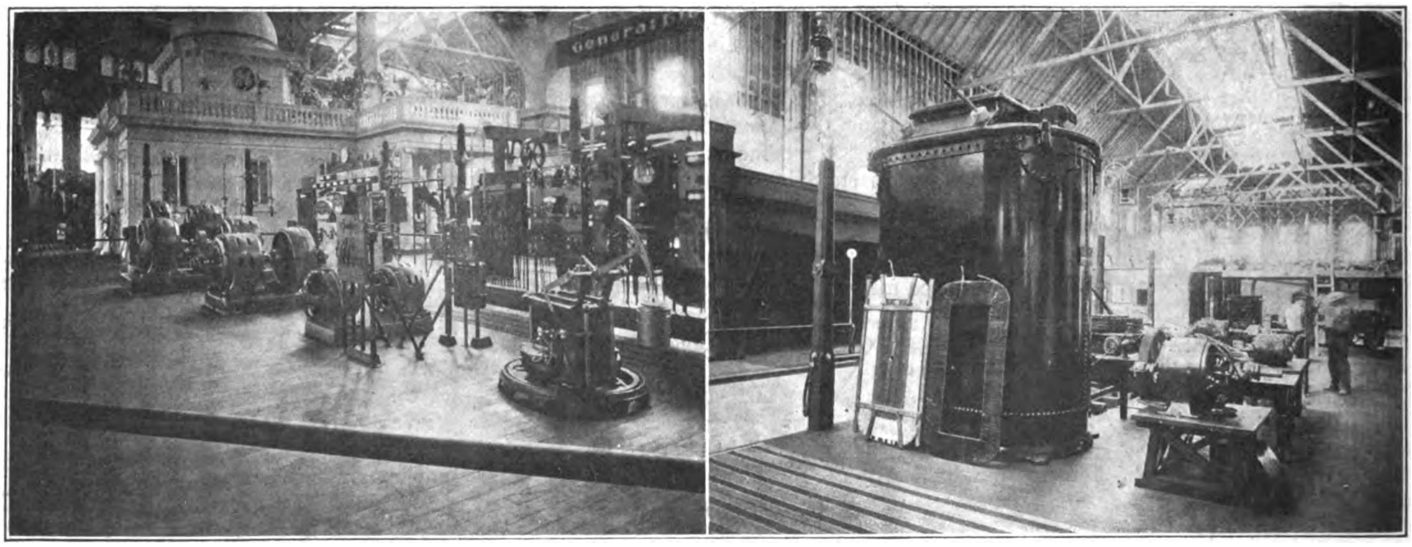
A mercury vapor rectifier with a capacity of 10 amperes, direct current is shown side by side with a motor-generator set for doing the same work, the cost of which is double that of a mercury vapor rectifier. This rectifier takes single-phase alternating current at one pair of terminals and delivers direct current at another pair. The one shown in the exhibit receives 220-volt alternating current at 60 cycles and delivers 70 volts direct current. The efficiency of the rectifier is 75 per cent. The maximum capacity of a rectifier output is 10 amperes, direct current. If more than 10 amperes is wanted, more tubes are added.



SMALL MOTOR APPLIANCES IN GENERAL ELECTRIC EXHIBIT.

CHAPMAN VALVE MFG. CO.
BOSTON, U.S.A.

ELECTRICALLY OPERATED VALVE.



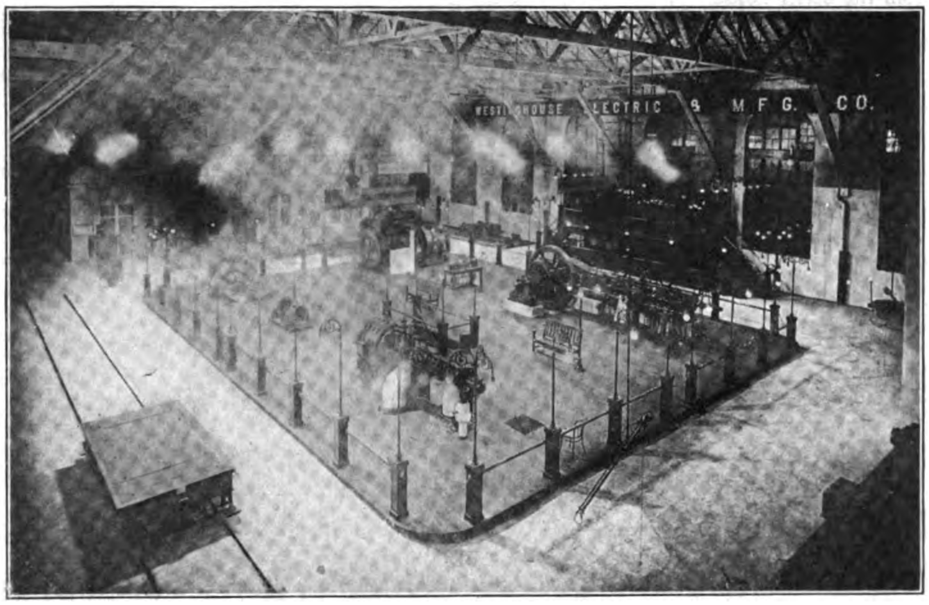
PORTIONS OF THE GENERAL ELECTRIC COMPANY'S EXHIBIT.

In one corner of the exhibit is a "tub" transformer with case removed showing the General Electric series alternating arc system. The 25 arc lamps supplied by this transformer are used about the company's exhibit. This is the system used by the Exposition for lighting the interior of the Exposition buildings, the Pike and outlying portions of the Exposition grounds. In connection with the arc lamps, the concentric diffuser is, of course, shown, and also a new white ceiling of metal, for use with arc lamps, to improve the general illumination.

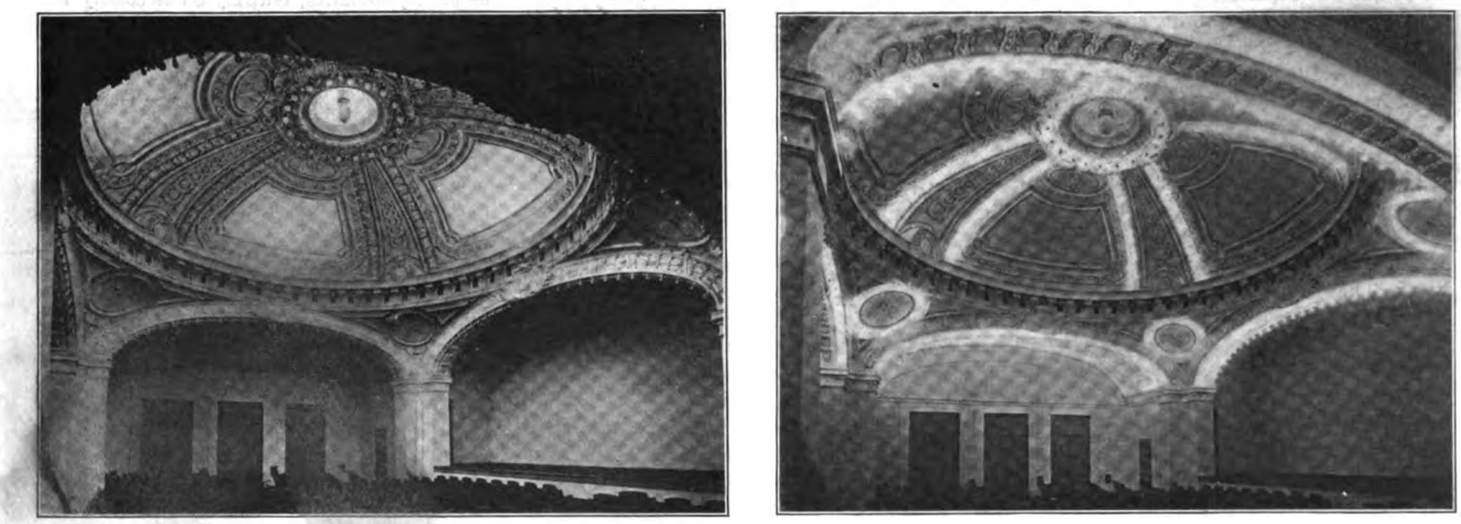
A great number of small motor appliances are shown, including a 24-in. electrically operated Chapman valve, centrifugal sugar-drying outfit with direct-connected, vertical shaft motor, portable drilling outfit with flexible shaft, alternating and direct-current sewing machine motors, electric motors, electric coffee grinder, electric buffing and grinding machines, electric meat chopper, horse-clipping and grooming machine, forge blower, job printing press, automatic envelope printing machine and a regular drill press. Voltage regulators, types TA, TD and AR, are in operation with loads which may be varied. An 18-in. searchlight electrically controlled from the main floor surmounts the tower of the company's office booth in the middle of the exhibit. The latest products of the company in wiring supplies, lamp sockets, insulators, cabinet panels, with all its classes of small work, are shown, but space does not permit a minute description of all improvements made in these small parts. An apparatus whereby a large number of condensers are charged in parallel and discharged in series so as to give one million volts is set up, and used in testing lightning arresters with a discharge similar to lightning discharge. Typical railway and lighting switchboards of several types are used in operating apparatus in the exhibit.

The exhibit of measuring instruments is especially interesting because a number of the company's new curve-drawing wattmeters and voltmeters are shown as well as the regular indicating instruments. A Thomson high-torque induction recording wattmeter is connected with a bank of lamps to show its operation on from one to sixty 4-c.p. lamps. The Thomson prepayment wattmeter can also be seen, as well as the new designs of Thomson recording wattmeter in different capacities.

THE WESTINGHOUSE EXHIBITS.—The main service plant at the Exposition which was designed and installed by Westinghouse, Church, Kerr & Co., is a notable feature of the Westinghouse exhibits which appeals, because of the commanding size of the electric generating units, each of 2000-kw. capacity, and their location in the central aisle of Machinery Hall, to practically all visitors to the Fair. The generators operate at a speed of 85 revolutions per minute and deliver a 25-cycle current at 6600 volts. Entrance to the service plant exhibit is through a large 35-foot plaster ring molded in close representation and in exact duplicate size of the stationary armature of the 5000-kw., alternating-current generators constructed for the elevated and subway train service in New York City. The total space devoted to the service electric plant in Machinery Hall, with the exciter units, condensers, cooling towers, and the 35-panel switchboard, is 26,260 square feet, and although within the Westinghouse walls at the west end of Machinery Hall, has not been laid out on elaborate lines to combine the diverse characteristics of exhibition and service, and is an exhibit plant only in so far as it is representative of modern practice at minimum cost. The various organizations associated with the Westinghouse name, which have united in representation at St. Louis under the title of the "Westinghouse Companies at Louisiana Purchase Exposition," have additional adjoining exhibit space in Machinery Hall, of 26,260 sq. ft., space in the Palace of Electricity of 10,100 sq. ft., where Baldwin-Westinghouse electric trucks and locomotives also are shown, and space in the Palace of Transportation of 3000 sq. ft., a total of 65,620 sq. ft. The Westinghouse exhibits and preparations for the reception and entertainment of visitors constitute a noteworthy feature of the industrial display at the Exposition. In Machinery Hall is the Westinghouse auditorium, which seats 350 persons, in which are displayed at regular hours through the day the biograph and mutoscope pictures of scenes in and about the various Westinghouse works in the Pittsburg district, including the first interior photography of the kind ever taken by means of the Cooper Hewitt mercury vapor lamp. Through the courtesy of the companies, this auditorium, which is rendered cool and comfortable by a ventilating system, and brilliantly lighted by the four principal systems of electric illumination, will be used throughout the Fair as a meeting place for scientific societies and technical congresses. The lighting of the hall is with the incandescent lamps of the Sawyer-Man Electric Company, Bremer arc lamps, Cooper Hewitt mercury vapor lamps, and the Nernst glowers, all of which are used extensively throughout the Westinghouse display. The Cooper Hewitt lamps are shown in the booths in Machinery Hall and in the Palace of Electricity as designed for use in general illuminating, photographing and photo-engraving. The lamps are in use on the grounds and in various exhibits, and never fail to excite comment. The most striking use of the lamp, however, is in the eight-foot tubes which are hung over the entrance to the Westinghouse auditorium and over the entrance to the Cooper Hewitt booth in the Palace of Electricity. There are in all about 10,000 Nernst glowers in use in the Exposition buildings, 6,000 of them in the Fine Arts Museum. It is interesting to recall that the first public appearance of the Nernst lamp in any considerable number was only three years ago, at the Pan-American Exposition. To-day the new lamp is playing a very prominent part in the illumination of the world's greatest exposition. On exhibition or in service the Westinghouse Companies have installed within the Exposition grounds 14,000 horse-power in generating machinery and 30,000 horse-power in other apparatus.

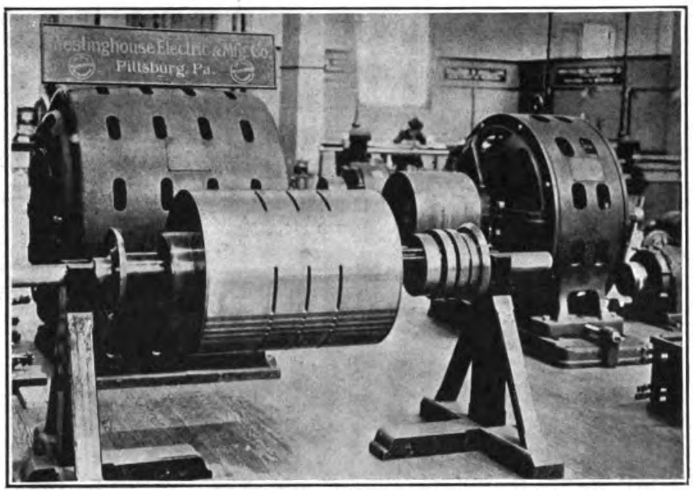


PART OF THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY'S EXHIBIT.



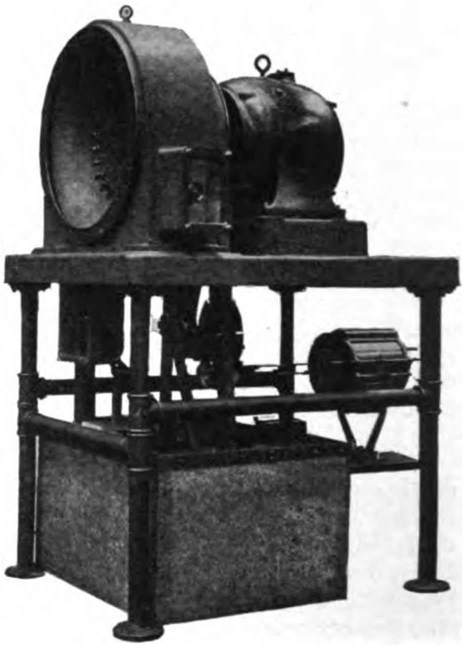
VIEWS SHOWING SUPERIORITY OF COOPER-HEWITT MERCURY VAPOR LAMPS OVER INCANDESCENT LAMPS FOR PHOTOGRAPHIC PURPOSES.

The Sawyer-Man Co.'s display of various types and sizes of its well-known incandescent lamps is in the general Westinghouse exhibit space in the Palace of Electricity. There, also, the Bryant Electric Company shows a variety of lamp sockets, receptacles, switches and other products, including details manufactured by the Perkins Electrical Switch Manufacturing Company. The R. D. Nuttall Co.'s exhibit of cut and planed gears, trolleys, trolley gears and pinions, for electric railway, mine and industrial haulage motors, is in Machinery Hall, near the Westinghouse headquarters. Steam for the electric service plant is piped from the boiler house, nearby, in which there has been installed a large battery of Babcock & Wilcox water tube boilers built into a single setting, with a total capacity of 6400 horsepower. Equipment here includes also Roney mechanical stokers at the furnaces, operated by Westinghouse standard steam engines, a complete coal conveying system furnished by the Link Belt Engineering Company, Cochrane feed water heaters, Worthington steam pumps, mechanical draft condensers, cooling towers and other apparatus to be found in a model station of the present day. The auxiliary apparatus in the electric plant includes three 80-kw., direct-current, 125-volt, direct-connected, engine-driven exciter units, two of which are sufficient to operate the entire plant and adjacent auxiliary machinery in the exhibit sections. Each of the four chief generating units receives steam from a separate line, supplied by a separate battery, the entire plant thus consisting of two sections which may be operated independently or together. The exhibit service plant, immediately west of the Companies' headquarters, is utilized to furnish power for various purposes, and includes a Westinghouse-Parsons steam turbine generating set of 400-kw. capacity, operating at a speed of 3600 r.p.m., and delivering a three-phase, 60-cycle current at a potential of 440 volts. The unit selected for exhibit is at the present time the smallest turbine unit built by the Westinghouse Machine Company. The construction of the rotating field of the generator shown in connection with the turbine on exhibit may be studied in the exhibit in the Palace of Electricity, where one of similar type is set up but not in operation. The exhibit service plant contains also a 125-h.p. vertical and a 225-h.p. horizontal gas engine, the first direct connected to standard two-wire, the second to standard three-wire, double-voltage, direct-current generators. Both single-acting and double-acting types of gas engines at present manufactured by the Westinghouse Machine Company are here represented in their latest form. An important part of the installation which is seen by few is the pumping apparatus under the beautiful Cascades in front of Festival Hall. This equipment was designed to supply 90,000 gallons of water a minute for these Cascades, by three large centrifugal pumps each driven by a 2000-h.p. induction motor. In the Palace of Electricity, the company occupies a space of over 10,000 sq. ft., including 1600 sq. ft. devoted to the display of electric trucks and locomotives constructed in conjunction with the Baldwin Locomotive Works. In the regular electrical equipment display are a 400-kw., turbine-type generator; typical generators for direct and alternating currents; for belt or direct connection; rotary converters; motor-generator sets; oil insulated and air blast transformers; direct-current and alternating-current railway motors and controllers; single and polyphase induction motors of constant and variable speeds; direct-current motors of many types, including motors for variable speed service from single and double-voltage circuits, switchboard apparatus, ammeters, voltmeters, wattmeters, synchroscopes, power factor meters, circuit breakers and switches, many of them electrically operated; portable instruments; instruments of precision; potential regulators, and innumerable other forms of auxiliary apparatus and instruments. The alternating current series wound, single-phase crane motors, similar in type and general construction to the single-phase railway motors exhibited in the Transportation Building, and the new unit switch system of multiple control are also to be seen in this section.



ROTATING FIELD OF TURBINE GENERATOR.

THE PELTON WATER WHEEL COMPANY'S exhibit, although covering a relatively small area, is very instructive. It consists of a 20-in. Pelton water wheel overhung on the shaft of a small General Electric generator and operated by water delivered in the usual manner through a needle nozzle and supplied from a centrifugal pump. The rim of the wheel at the point where the jet of water strikes the buckets is illuminated at fixed intervals by rays of light from a General Electric searchlight located beneath the wheel. The light beam is delivered into the wheel housing through a window in the bottom by a system of mirrors. Interposed between the searchlight and the water wheel is a sheet-iron disc with radial slots, the disc being revolved by means of gearing at a speed proportional to that of the wheel, so that the light passing through the rapidly moving slits illumines the wheel bucket at fixed intervals corresponding to the passage of each bucket at the point where the jet impinges. The result is that one sees the wheel apparently standing still and is able to observe the action of the water in the buckets and trace the path of the jet from the time it enters the bucket, through its reversal, to the clearance of the succeeding bucket. This apparatus makes it clear to the observer that the front lip of each bucket produces no disturbance of the water jet in entering the jet, that the water velocity is taken up on the surface of each bucket in a line vertical along the shaft center, and that the water is discharged from the sides of each pair of buckets without interference with the next succeeding pair or with the web of the wheel. No water is carried around with the wheel, the discharge occurring as soon as the water has transferred its kinetic energy to the rotating wheel. The exhibit is probably the most powerful argument in favor of the Pelton water wheel that could be made, obviating entirely all necessity for verbal argument so far as those who understand the fundamental principles of water wheel operation are concerned.



APPARATUS FOR OBSERVING WATER-WHEEL IN OPERATION.

THE DAYTON ELECTRICAL MANUFACTURING COMPANY, Dayton, Ohio, exhibits the Apple ignition apparatus. In addition are shown storage batteries, jump spark coils, contact coils, plugs, timers and magnetos made by this company. A 20-h.p. unit supplies the current for operating the exhibit and lighting a large sign. This engine is ignited by either jump spark, the touch spark or the Apple electric flame at the option of the attendant. On the switchboard a new design of ignition meter shows the number of charges taken by the engine and the number of charges ignited by each of the three systems mentioned, thus showing the comparative merit of each. On a long table are a dozen fly-wheels of various sizes operating twenty-four ignition dynamos fitted with Apple governors, which are said to maintain the speed of the generators constant regardless of the speed of the gas or gasoline engines.

THE OTTO GAS ENGINE WORKS, of Philadelphia, occupy a large space in Block 41, Aisles D and E, of Machinery Hall. The general display is consistent with the high grade of the Otto engine. There are seventeen engines for general and special work, eleven of which are fitted up and running, ranging in sizes from 2 to 140 horsepower. There are several features of more than ordinary interest, including a 40 h.p. horizontal, single-cylinder engine direct-connected to a Diehl generator, and a special electric light type of engine, fitted with a patented rotary ball governor which regulates on the "hit-and-miss" plan. The regulation of this engine is claimed to be perfect, giving a variation in voltage not exceeding 2 per cent. from full load down to but a few lights. The claim for this engine is that, being of the single-cylinder type, it requires less attention and is very much simpler in construction than an engine having a multiplication of cylinders in order to get the regulation for electric light purposes.

With this method of governing, the idle running gas consumption is said to be less than 18 per cent. of full load consumption, which, it is claimed, is more economical than the throttling method of governing or an engine having a multiplication of cylinders.

The two largest types of engines shown embody the latest features for large engine construction. They are fitted with self-starters, the method of starting being to set the engine at the point of ignition and with a hand pump deliver a charge into the cylinder; after the cylinder is charged it is cut off and a somewhat greater pressure is pumped into a vessel which is part of the starter, after which the hand lever is opened, allowing the greater pressure in the vessel to enter the engine cylinder and slowly turn the engine over, when the igniter snaps and the charge is ignited, which gives the flywheel sufficient momentum to draw in the next charge by the engine in the regular way.

All of the engines are fitted with electric igniters having both movable and stationary electrodes mounted in a phosphor bronze flange.

The marine-type, vertical, two-cylinder engine is of the standard Otto construction employed for submarine boats. Two types of pumping engines are shown, vertical and horizontal, the pump being directly geared to the engine, making a very compact design. There is also a 10-h.p. engine belted to an electric generator. The space is very brilliantly lighted by arc and incandescent lamps, which are supplied from dynamos run by engines in the exhibit space.

The company also exhibits a number of awards, gold and silver medals, which have been received at other prominent expositions; the company claims the distinction of having over a hundred gold and silver medals and numerous awards and diplomas.

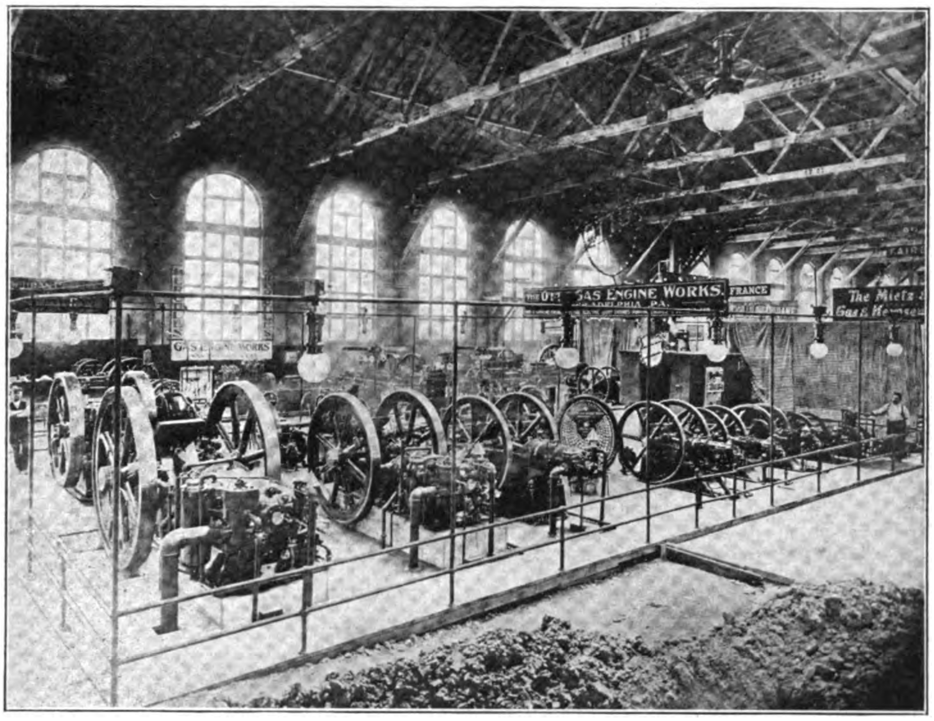


EXHIBIT OF OTTO GAS ENGINES.

NEW BOOK.

SPANGENBERG'S STEAM AND ELECTRICAL ENGINEERING. By E. Spangenberg, Albert Uhl and E. W. Pratt. St. Louis, Mo.; George E. Zeller. Cloth; 695 pages, 5½ ins. x 8½ ins.; over 600 illustrations. Price, $3.50.

This book belongs partly to the class of catechisms which have become so familiar in steam engineering, and as its title indicates, the authors endeavor to cover both steam and electrical engineering within the one volume. The catechism form, however, is restricted to the steam engineering section. In this section the properties of steam, the different thermometers, different types of steam boiler, engines, steam gauges, injectors, pumps and heaters are explained in elementary language, and the proper care of boilers, engines and other apparatus is indicated. The steam section also contains a considerable discussion of locomotives. In the electrical section the authors start out with an explanation of the fundamental units, followed by a discussion of simple circuits, electromagnetism, magnets and the dynamo. This is followed by a chapter on the details of armature winding, one on motors and motor control, and another on measuring instruments. The authors next discuss incandescent and arc lamps, storage batteries, alternating currents and apparatus, wiring calculations and the installation and repair of electrical apparatus, closing with a list of probable troubles and the remedies for them. This section is followed by a short one on compressed air apparatus, another on gas and gasoline engines, one on mechanical refrigeration, and still another on hydraulic elevators. The book closes with a brief chapter on machine shop repair work, which also contains a list of workshop recipes and useful tables and formulas.

A UNIQUE POWER-PLANT SALE.

Central station managers seeking an opportunity to purchase advantageously equipment for a power plant will be apt to find it in the disposal of the service station of the Louisiana Purchase Exposition. This plant is described in another part of this issue. It has a capacity of about 14,000 horsepower and was designed and installed by Westinghouse, Church, Kerr & Co., to illustrate the best practice in plants of such size. The equipment must be removed at the close of the Exposition and will be sold in whole or in part for immediate delivery when the fair is over.

The equipment was all new when installed and has been used just enough to insure the good running condition of all parts. There are four vertical cross compound engines, with 38-in. and 76-in. cylinders, 54-in. stroke, fitted with Monarch safety stops. Two of these engines are direct-connected to General Electric 2000-k.w. generators and two of them to Westinghouse generators of the same capacity; these are 3-phase, 25-cycle, 6600-volt machines of the revolving field pattern. Steam is furnished by sixteen 400-h.p. Babcock & Wilcox boilers equipped with Roney stokers.

The auxiliary apparatus includes a Worthington Admiralty pattern boiler feed pump, two Worthington compound feed pumps, two Cochrane feed-water heaters and purifiers, four 14-ft. mechanical draft fans, each driven by a Chandler & Taylor automatic engine, two Worthington elevated jet condensers, a Worthington vertical dry vacuum pump and two Worthington horizontal flywheel dry vacuum pumps, sixteen Seymour fans driven by a Westinghouse compound engine, three Worthington Volute centrifugal pumps, three Westinghouse 80-kw. exciter units, a switchboard and all its appurtenances, and a 40-ton, 80-ft., 3-motor, Niles-Bement-Pond crane. In addition there is a large amount of steam and water piping, valves, gauges, traps and apparatus used in the Holly system for returning condensed water to the boilers. So many conjectures have been made concerning the disposition of this plant after the close of the Exposition that we are glad to be able to make this announcement.

NOTES FROM THE CONTRACTORS' CONVENTION.

There was in evidence at the National Contractors' Convention held at St. Louis a contingent of manufacturers and representatives worthy the National Electric Light Conventions in the best days of the "Exhibit" feature.

The Nernst Lamp Company: A. K. Hurst, St. Louis.

V. C. Gilpin was on hand to discuss DeVeau telephones.

American Carbon & Battery Company, St. Louis: Mr. Henry Wrape.

American Conduit Manufacturing Company, Pittsburg, C. A. Flack.

The Phelps Company, Detroit: Messrs. W. E. Phelps and J. W. Phelps.

Dayton Electrical Manufacturing Company, Dayton, Ohio: Mr. G. Apple.

The Benjamin Electric Manufacturing Company, Chicago, Ill., B. B. Benjamin.

American Electrical Heater Company, Detroit: Mr. B. H. Scranton, president.

Habirshaw wires had as sponsor Manager J. B. Olson, of the New York Office.

Mr. Robert Garland represented the Safety Armourite Company, of Pittsburg.

W. H. Morton, of Johnson & Morton, Utica, N. Y., made many new friends.

Mr. W. S. Sissons, of Providence, was there to talk the merits of D. & W. fuses.

Faries Manufacturing Company, of Decatur, Ill., was represented by Dr. W. J. Grady.

"Diamond H" switches were spoken for by Mr. W. P. Crockett, of the Chicago office.

Mr. Charles E. Lee came from Boston to represent the Electric Gas Lighting Company.

The Electric Appliance Company, of Chicago, sent its very best—Mr. William W. Lowe.

Pass & Seymour were represented by Messrs. Salsbury and Brooks, of the Syracuse office.

The Pardridge Shade & Reflector Company, Chicago, was represented by Mr. J. S. Pardridge.

W. R. Ostrander & Company sent Messrs. Vaughan and Monk to look after their interests.

Hart & Hegeman Manufacturing Company, Hartford: Mgr. George S. Searing, of the Chicago office.

Franklin Electric Manufacturing Company, Hartford and New York: Mr. Charles I. Hills, president.

Bossert Electric Construction Company, Utica, N. Y., had President Bossert himself as representative.

The Sprague Electric Company had the Greenfield conduit well spoken for by Mr. Alex. Henderson.

Gould Storage Batteries were ably championed by Messrs. W. W. Donaldson, E. L. Draffen and A. S. Hubbard.

H. B. Coho, New York representative of the Keystone Electric Company, Erie, Pa., was on hand in the interests of his company.

Condit Electrical Manufacturing Company, Boston, was represented by Mr. Fred W. Nason, who explained the merits of Eden circuit-breakers.

The Seidler-Miner Company, of Detroit, had Mr. Frank J. Miner in attendance. Mr. Miner has just recovered from a very serious illness.

Mr. Hugo Reisinger, in addition to his duties as World's Fair Commissioner and Juror, had time to make known the merits of "Electra" carbons.

The Ewing-Merkle Electric Company, St. Louis: Messrs. A. P. Ewing, W. S. Merkle, W. G. Brown, A. L. Philo, T. P. Gleeson, W. G. Sims, R. L. Faries.

The Wagner Electric Manufacturing Company, St. Louis, was represented by Mr. W. A. Layman and various members of its engineering and sales departments.

Manhattan Electrical Supply Company had two sturdy representatives in Messrs. McDowell and Pierce, from the New York and Chicago offices respectively.

Of the Missouri American Electric Company, St. Louis, Mo., Mr. A. W. Miller, president, and Mr. George P. McDowell, vice-president, remained in St. Louis.

The Warren Electric Manufacturing Company, Sandusky, Ohio, was represented by the staff of the Wesco Supply Company, the local agent for the Warren alternators.

"Flexduct" was ably represented by Messrs. C. E. Corrigan, Harry Osburn and C. B. Roulet. Mr. Bennett, Chicago representative, was also in attendance as an understudy.

The Locke Insulator Manufacturing Company, Victor, N. Y., was represented by the staff of the Wesco Supply Company, which company is the local agent for the Locke insulators.

The Columbia Incandescent Lamp Company, St. Louis, Mo., entertained at its new factory. Mr. Garrison, president of this company, and associates were "at home" during the entire week.

The Schaeffer & Budenberg Manufacturing Company had Mr. A. L. Portong in attendance, and its exhibit of steam specialties at the Fair attracted much interest among the delegates.

Crocker-Wheeler Company, Ampere, N. J., was represented by its president Dr. Schuyler S. Wheeler, Messrs. Gano S. Dunn and Rodman Gilder and other members of the engineering and commercial departments.

The Dale Company, New York, was represented by John H. Dale and O. J. Bryan, from New York, who distributed a handsome souvenir of their new wireless cluster that has met with such marked success.

John A. Roebling's Sons Company sent two able delegates in Frank W. Harrington and G. W. Swan, and while Mr. H. L. Shippy could not be there, he sent a neat little characteristic souvenir in the shape of a corkscrew made of Roebling wire.

Wesco Supply Company, St. Louis, was naturally strong in its representation, Messrs. Roger Scudder and A. L. Scudder, J. E. Ecoff, N. J. Roth, F. S. Weimeyer, A. A. Marr, George F. Schminke, V. E. Raggio, R. S. Waldfield, J. W. Krueger and G. W. Cooper being almost constantly on hand.

The American Circular Loom Company was kept constantly in mind through the strenuous efforts of Messrs. H. B. Kirkland, T. H. Bibber and Thomas G. Grier. This was Mr. Kirkland's first convention since his serious illness of last spring, and he was congratulated on all sides on regaining his "old form."

The American Diesel Engine Company, New York, was represented by Mr. Norman McCarthy, sales manager. The sixty-thousand-dollar installation of the Diesel oil-burning engines made by this company for lighting the Tyrolean Alps on the Exposition grounds attracted much attention from visiting engineers.

OBITUARY.

J. B. RAMP, of the Murray Iron Works, Burlington, Ia., died recently at the age of seventy-four years. Mr. Ramp was for nearly twenty-five years superintendent of the foundry of the Murray Iron Works and was held in the highest esteem by both his employers and his subordinates. He was a native of New York City and was a Civil War veteran.

PHILIP W. MOEN, formerly of the Washburn & Moen Manufacturing Company, Worcester, Mass., died on September 12 from a stroke of apoplexy. Mr. Moen was one of the pioneers in the manufacture of wires for electric light and power circuits. At the time of his death he was a director of the Worcester Consolidated Street Railway Company and the Boston & Worcester Street Railway Company.

RICHARD S. WARNING, a founder of the Standard Underground Cable Company, died recently at Elmira, N. Y. Mr. Waring was born in Saratoga County, N. Y., in 1833 and went to Pittsburg, Pa., when he was about twenty-three years of age. After widely varied and successful experiences in other lines of business, Mr. Waring organized the Standard Underground Cable Company in 1882, and although there was at that time practically no market for underground cables in this country he spent money liberally in perfecting the cable system and methods of manufacture which have made the company one of the most successful in the world. In 1887 Mr. Waring organized in England the Fowler-Waring Cables Company, Ltd., for the manufacture of the same line of cables then being turned out by the American company. About five years ago he was obliged to retire from active business on account of failing health and had since resided at Elmira.

PERSONAL.

DR. F. A. C. PERRINE, formerly vice-president of the Stanley Electric Manufacturing Company, Pittsfield, Mass., has entered the field of consulting engineering, with headquarters at 49 Wall Street, New York.

MR. F. V. HENSHAW, for several years past a prominent member of the engineering staff of the Crocker-Wheeler Company, has resigned his position with that company and is now taking a well-earned rest before engaging in other work.

MR. BUDD FRANKENFIELD has resigned his position on the engineering staff of the Nernst Lamp Company to accept a position in the engineering department of the Bullock Electric & Manufacturing Company, Norwood, Ohio.

MR. R. C. ROUTLEDGE, formerly connected with the firm of Thomas F. Smith & Co., New York, has been placed in charge of the contracting department of the H. W. Johns-Manville Company, this city, and will give his personal attention to all inquiries and orders.

MR. J. A. GORDON, of the International Telephone Manufacturing Company, Chicago, has been put in charge of the new construction work of the Public Service telephone system in the town of Neepawa, Manitoba, which system is being practically doubled in capacity.

MR. L. P. HAMMOND has resigned his position as manager of the Denver branch office of the Crocker-Wheeler Company to accept the sales managership of the Denver Engineering Works Company. Mr. Hammond's headquarters will be at the Denver office of the company.

MR. ARTHUR HARTWELL, who for a number of years has been general sales manager of the Westinghouse Electric & Manufacturing Company, has resigned that position to accept the position of general manager of the Sterling Varnish Company of Pittsburg.

MR. O. H. ENSIGN, who has been prominently connected with the Los Angeles Edison Electric Company, has resigned his position there to accept one as consulting engineer with the United States Reclamation Service. Mr. Ensign will have supervision of all of the electrical and hydraulic power development work of the Reclamation Service and will have his headquarers in Los Angeles.

MR. EDWARD E. GOUDEY, formerly general manager of the Goudey-McLean Company, who recently resigned that position to take a partnership interest in the engineering firm of B. F. Bell & Company, has since joined in the organization of the Bell Engineering & Construction Company to succeed the firm of B. F. Bell & Company in the business of consulting and contracting engineering.

MR. G. STANLEY RICHMOND, recently a member of the engineering staff of the Interborough Railway Company, has established headquarters in the Morton Building, New York, where he will engage in consulting electrical engineering. Mr. Richmond was in charge of the recent inspection of the ground return systems of the Richmond (Va.) electric railways. He will make a specialty of investigations and reports in this particular field and also upon underground distributing systems and fuel testing departments in power houses and central stations.

TRADE PUBLICATIONS.

BLAST FURNACE PLANTS. The William D. Pollock Company, Youngstown, Ohio.—A superbly executed book, containing half-tone illustrations of a number of modern blast furnaces which have been erected by this company and also of some of the chief detail apparatus.

ELECTRIC HOISTS AND WINCHES. C. W. Hunt Company, West New Brighton, N. Y.—Catalogue No. 046, containing a detailed description of the Hunt electric hoists, winches and capstans, in connection with which both direct-current and alternating-current motors are used.

RUST WATER TUBE BOILERS. The Rust Boiler Company, Pittsburg, Pa.—A handsome catalogue of standard size containing a well-illustrated description of the Rust boiler construction, some remarks on the selection of boilers and a discussion of types different from the Rust boiler.

TELPHERAGE FOR COAL HANDLING IN POWER STATIONS. United Telpherage Company, Westfield, N. J.—This is circular No. 52 describing the Telpherage Company's system for handling coal in gas works, electric light and power stations and other large manufacturing establishments.

PUMPING MACHINERY AT ST. LOUIS. International Steam Pump Company, New York.—This is a reprint of an article published in the *Iron Age* on the pumping and air-compressing machinery at the Exposition, this machinery, it is scarcely necessary to say, being of the Worthington manufacture.

DIRECT-CURRENT TURBINE-DYNAMOS. De Laval Steam Turbine Company, Trenton, N. J.—This is bulletin No. 2, containing an illustrated detailed description of the turbine-dynamo outfits built by this company in sizes ranging from 7 to 300 horse-power for direct-current service. The company has also issued bulletin No. 6 calling attention to De Laval turbine blowers.

A. B. C. STEAM ENGINES. American Blower Company, Detroit, Mich.—Bulletins Nos. 162, 163 and 164, devoted respectively to Type F vertical engines, Types B and C vertical engines and Type I horizontal engines. The Type F engines are built in three styles, one with automatic shaft governor, another with the ordinary flyball throttling governor, and the third without any governor for direct-connection to blower fans. Types B and C are all equipped with automatic governors of the Rites design and intended primarily for direct-connection to dynamos. The Type I engine is built in three styles corresponding to those of Type F.

OPINIONS OF THE AUTOMATIC TELEPHONE. Automatic Electric Company, Chicago.—Two attractively executed pamphlets, one containing a large number of opinions concerning the service of the automatic exchange in Grand Rapids, Mich., and another containing similar opinions concerning the service of the automatic exchange in Portland, Me. The testimonials are signed by prominent citizens in both places and all are extremely complimentary. The annual report of the secretary of the Grand Rapids company has been published in pamphlet form by the Automatic Company and makes an excellent showing for the automatic exchange in Grand Rapids.

AIR BRAKE TESTING. The Westinghouse Air Brake Company, Wilmerding, Pa.—This is a splendidly executed book of 323 pages, containing a vast amount of highly valuable information on the subject of air brakes and air brake tests. Beginning with a short chapter on the growth of car braking, the book presents most complete reports of the Galton-Westinghouse tests made in England in 1878, Paris and Lyons tests made in 1879, the Burlington Railway trials made in 1886 and 1887, and so on throughout a long list of important tests of air brakes on steam railroads, the latest being those made last year on the Central Railroad of New Jersey at Atsion Station. All of the trials were competitive and in all of them the Westinghouse system made the best showing.

BUSINESS NEWS.

ELECTRO DYNAMIC COMPANY, Philadelphia, Pa., has removed its manufacturing headquarters to Bayonne, N. J., where a new large factory, well equipped for the production of dynamos, motors and other apparatus, has been established. The local address is corner of Avenue A and North Street.

MACHADO & ROLLER, New York, have been appointed Eastern sales agents for the dynamos and motors built by the Fidelity Electric Company, Lancaster, Pa. The Fidelity Electric Company makes a specialty of small machines, including special polishing and buffing motors, vertical type motors, small rotary converters, etc. Machado & Roller will carry a complete line of the representative sizes in stock in New York.

THE MACON-EVANS VARNISH COMPANY has been organized in Pittsburg for the manufacture of high-grade varnishes and insulating materials, with main office and works at Esplen Borough. L. S. Macon is president of the company and Cadwallader Evans, Jr., is secretary and general manager. Mr. Macon was for a number of years secretary of the Sterling Varnish Company; Mr. Evans was formerly with the Oliver Iron & Steel Company, of Pittsburg.

GOULD STORAGE BATTERY COMPANY, New York, reports among recent contracts the following: City & Suburban Railway Company, Portland, Ore., a 280-cell battery and regulating booster; Edison Electrical Illuminating Company, Topeka, Kan., a 280 cells battery and regulating booster; Leominster, Shirley & Ayer Street Railway Company, Shirley, Mass., 224 cells; Corporation of the Town of Port Arthur, Canada, 240 cells. The company has also installed a large number of batteries in isolated plants recently.

THE SPRAGUE ELECTRIC COMPANY, New York, is enjoying an excellent business in electrical hoisting apparatus. Among recent orders are eight electric hoisting outfits to be used in handling castings in the construction of the new Pennsylvania Railroad tunnel in this city, thirteen hoists for the Pennsylvania Railroad car wheel foundry at Altoona, and twenty for the new works of the International Steam Pump Company, Harririson, N. J. The company's flexible metallic conduit is used throughout the cars of the subway system in New York for the lighting circuits. This conduit, it may be remembered, is a flexible one consisting of steel tapes wound spirally into tubular form.

THE STERLING ELECTRICAL MANUFACTURING COMPANY, Warren, Ohio, which was awarded the contract last year for the United States Navy supply of incandescent lamps aggregating approximately 160,000 lamps, announces that it has not only filled the rigid requirements of the contract, but has not had a single lamp rejected as the result of life tests or drop in candle-power tests, and the number rejected on photometer readings is remarkably small. The original contract has been supplemented by additional orders from the government, so that the number of lamps actually supplied will aggregate about 200,000. The company is still filling government orders satisfactorily, and is fully equipped to handle any large requirements on close specifications.

MARINETTE GAS ENGINE COMPANY, Chicago Heights, Ill., is now well established in its new factory plant, which is favorably located, large, roomy, well lighted and excellently equipped. The company has recently made some important shipments of gas engines for electric light service, including several engines direct-connected to generators which were sent to Lisbon, Portugal. Among some of the larger installations are three 85-h.p. direct-connected engines in the Pittsburg Post Building, Pittsburg, Pa.; three 125-h.p. direct-connected outfits in the Pittsburg Exchange Building, and nine 85-h.p. direct-connected units in the Diamond Light & Power Company's plant. The company has recently secured a contract from the United States Government for the installation of a 75-h.p. engine for direct connection to a generator at Fort Hamilton, N. Y.

DODGE & DAY, of Philadelphia, Pa., have been commissioned by Alexander Brothers, of that city, to take charge of the electrical installations in the property recently acquired by them. A generator will be required, several motors, switchboard, line-shafting, wiring, etc. These engineers have just placed orders for two horizontal high-speed engines of 160 and 240-h.p. respectively with Ames Iron Works, Oswego, N. Y.; 600-h.p. of tubular boilers with Ervien & Company, Philadelphia, and 100 and 150-kw. generators with Crocker-Wheeler Company for the Victor Talking Machine Company's new plant in Camden, N. J. Other commissions of this firm are the purchase and installation of a night set for the new plant of the Jeanesville Iron Works Company, Hazleton, Pa., and the running of transmission line to Jeanesville (a distance of two miles) to furnish illumination for the town and residences; a heating system for residence of James C. Haydon, Janesville, Pa.; ten automobile garage and electrical equipment thereof for the Link-Belt Engineering Company, Nicetown, Pa.

THE REEVES ENGINE COMPANY, Trenton, N. J., and New York, has just published a most interesting bulletin containing the results of tests made by Professors Carpenter and Diederichs at Sibley College, Cornell, with a Reeves simple engine having a cylinder 15 inches diameter by 14 inches stroke. The average initial steam pressure of the various tests was 114 pounds. Running non-condensing the engine showed a consumption of 40 pounds of dry steam per hour per indicated horse-power at 37 horse-power, 30 pounds at about 77 horse-power and 28 pounds at 120 horse-power. The mechanical efficiency was 65% at 35 horse-power, 80% at 75 horse-power and 90% at 122 horse-power. Running condensing the steam per indicated horse-power-hour was 35 pounds at 27 horse-power, 27 pounds at 80 horse-power, about 26 at 120 horse-power and the same at 140. The steam per hour per developed horse-power condensing was 44 pounds at 25 horse-power, 28 pounds at 100 horse-power and 27½ at 140 horse-power, the mechanical efficiency being 95% at 133 horse-power (developed). When running condensing the vacuum was about 23½ inches.

THE NEW ENGLAND MOTOR COMPANY, Lowell, Mass., is bringing out a line of storage batteries for stationary and vehicle work, which, while not exhibiting anything startlingly novel in their construction, still show features of merit. The plates are of the pasted type, the oxides being applied to moulded grids in the usual manner. The negative plates, after being formed, are subjected to considerable pressure, so as to consolidate the spongy lead and make it more adhesive. The positive grids are oxidized before being pasted. In the vehicle battery cells grooved wooden separators are used. The wood is treated by a special process to prevent the formation of acetic acid or gum-dextrin. The details of this process are not given, but it has been the result of considerable experimentation on the part of the company. The New England Motor Company has been building these batteries for some two and a half years and using them on automobiles and launches with a view to thoroughly testing their efficiency and capability of withstanding hard usage. The results have more than come up to the anticipations. While no special effort has been made to obtain large output per pound in the vehicle cells, the performance is very creditable. The 150-ampere-hour cell for 4-hour rate weighs complete 28 lbs., and this is said to be lighter than any other cell of equal capacity on the market, being an output of 10 watts per pound of complete cell at the 4-hour rate. The grids, it is stated, are of such a form as to give great mechanical rigidity. Special machinery has been designed for the production of the plates, and prompt shipments can be made in almost any quantities. The company will, upon application, be pleased to furnish bulletins descriptive of these storage batteries.

CENTRAL STATION NEWS

ALABAMA.

SHEFFIELD.—Mr. George M. Morris is superintendent of the plant of the Sheffield Company.

MOBILE.—The Gulf Electric Company has filed articles of incorporation with the Secretary of State. The capital stock is $70,000 and the incorporators are J. H. Wilson, C. W. Chase, R. W. Jones and Sidney Lewenstein.

GADSDEN.—The Etowah Light & Power Company, which is building an extensive electric plant, has let the contracts for the operating machinery and other equipment. Capt. W. P. Lay, the owner of the company, states that between 500 and 800 horse-power will be transmitted to this city for lighting and power purposes.

ARIZONA.

GLOBE.—Mr. Charles M. Clark, of the Globe Power Company, announces that the project of establishing an electric power plant for this city and the adjacent mining camps will soon be developed in accordance with the original plans. The company has received from the Government the necessary grants of rights-of-way for its canal, transmission lines, etc. The company has already expended about $30,000 in surveys and preliminary work, and it is estimated that the cost of constructing and installing the plant will approximate $1,200,000. The minimum capacity of the plant when completed will be 6000 horse-power. The construction work includes one tunnel 7657 feet long and about eight miles of small tunnels, ditches and flumes.

ARKANSAS.

BOONEVILLE.—H. G. Sadler & Company have been granted a franchise for the establishment of an electric light plant.

FORDYCE.—Mr. J. M. Covey is superintendent and chief electrician of the Fordyce Light & Water Company, which also furnishes lighting current to Kingsland.

HARRISBURG.—It is reported that the business men of this city have secured a subscription of $4000 for the purpose of establishing water works and an electric plant.

THORNTON.—The Pine Bluff City Electric Company and the Stout-Greer Lumber Company, of Thornton, are said to have secured the contract for the installation of an electric light plant at Thornton.

FORT SMITH.—The Fort Smith Light & Traction Company has appointed H. M. Byllesby & Company, of Chicago, engineers to undertake the work of extending and improving its electric light, gas and power plant; extensions will also be made to the street railway system. The following are the present officers of the company: President, W. R. Abbott; vice-president, George T. Sparks; secretary and treasurer, R. G. Hunt; superintendent, G. H. Wilmarth; chief engineer, L. Robertson; chief electrician, J. F. Johnson.

CALIFORNIA.

HEALDSBURG.—It is necessary to readvertise for bids for the new machinery required by the increased demands on the power plant, as the contracts formerly awarded were not advertised for the required period.

FRESNO.—Messrs. W. M. Spencer and J. A. Stroud, of Oakland, are said to be interested with Fresno capitalists in a proposition to generate power near Tehipite Dome for use in Fresno and vicinity. They have organized under the name of the Tehipite Dome Power Company.

WINTERS.—Mr. E. D. N. Lehe, manager of the Dixon Electric Power & Water Company, of Dixon, this State, announces that preliminary arrangements have been made for the installation of an electric light and power plant in this city. He has lately completed the installation of the several power plants on the banks of Putah Creek, the last of which is within about six miles of Winters.

SAN FRANCISCO.—A representative of the California Gas & Electric Corporation informs us that the newspaper reports of the recent accident to the pipe line near the electric power station were greatly exaggerated. According to this authority, the damage consisted of the breaking of a length of pipe near the manifold, and this was repaired in three days at a cost not exceeding $3000; no injury was done to the power house.

LOS ANGELES.—The Edison Electric Company reports that it is now constructing a steel pole line from the plant at Santa Monica to connect that portion of its system originally known as the Edison System with the transmission system of what was formerly the United Electric Gas & Power Company. This connecting link covers a distance of some thirteen miles and joins the company's Los Angeles steam station No. 3 with the sub-station in course of construction at Inglewood.

SAN FRANCISCO.—Mr. H. W. Goode, president of the Portland General Electric Company, was chosen president of the Pacific Coast Electrical Association at the eighth annual convention held recently at Monterey. The association's constitution and by-laws were amended so as to permit corporations and individuals engaged in the distribution and generation of electric power to become members. Heretofore the membership had been limited to those engaged in the actual transmission of electric power to a distance.

REDDING.—Another power plant is projected in Shasta County to transmit current to Redding and other points. Mr. J. E. Frick, of Berkeley, who has filed on 40,000 inches of water to be taken from Rising River and Crystal Lake at a point six miles east of Redding, states that the capitalists who are behind him will form a company and install a power plant which will transmit electricity down the Sacramento Valley. The above-mentioned sources of water are also tributary to Hat Creek, from which the Shasta Power Company expects to divert water for its projected plant. It is said that an extensive transmission system will be constructed.

COLORADO.

GEORGETOWN.—The United Light & Power Company is building ten miles of transmission line which will carry current at 10,000 volts.

MANCOS.—The Mancos Electric Light Company, which began operations here in February of this year, is owned and operated by Mr. John Pinyan, who is manager and superintendent of the plant.

DURANGO.—The Durango Light & Power Company is installing new condensing machinery and will shortly add a 250-kw., 2200-volt, 60-cycle, single-phase alternator which will enable it to operate an alternating-current day circuit.

DENVER.—Mr. George D. James, civil and mining engineer, of this city, representing Eastern capital, has several surveying parties in the field for the purpose of gathering accurate data in Colorado, Utah, New Mexico, Arizona and California as to the feasibility of generating electric power from the facilities afforded by the largest rivers traversing those States and Territories, the principal streams under consideration being the Colorado, Green, Grand, Arkansas, Rio Grande, South Platte, Pecos and Gila rivers and their tributaries. It is proposed to furnish electricity to various mining camps and to supply to other sections water for irrigation and domestic purposes.

CONNECTICUT.

WINDSOR LOCKS.—Control of the Windsor Locks Electric Lighting Company has been acquired by Thomas C. Perkins, of Hartford, who recently disposed of the Mystic Electric Light Company. Mr. Perkins will take possession of the property about January 1 and will proceed to greatly enlarge and improve the plant and increase the water power in order to furnish a day service for light manufacturing; at present current is supplied for lighting purposes only.

NORFOLK.—The Norfolk Electric Light & Power Company has leased its plant in West Norfolk to the recently incorporated Canaan Company and the new company has taken possession. The streets of Canaan, which have been in darkness for the past three months, are being lighted by the Norfolk plant. Norfolk's lights will be furnished at the rate of $15 a year as at present. It is understood that the plant is to be remodeled and enlarged and will operate both day and night circuits.

FLORIDA.

MILTON.—The Milton Electric Light Company has been granted a franchise to erect and maintain poles and wires for the distribution of electricity for power and lighting purposes. Construction work is to begin within five months.

JACKSONVILLE.—Superintendent R. N. Ellis, of the city electric light plant, has been requested to submit an estimate of what extensions will be necessary in the electric lighting, water works and sewer systems in order to meet the demands of the city for the next ten years.

GEORGIA.

NEWNAN.—Reports state that it is proposed to either construct or purchase an electric light plant, and that a special election will be held to decide whether or not $20,000 bonds shall be issued for that purpose.

THOMASVILLE.—The Mayor and Council have entered a protest, with other citizens, against a bill introduced in the State Senate providing for ownership of lighting plants by municipalities and making compulsory the purchase of existing plants.

IDAHO.

IDAHO FALLS.—It is reported that the Idaho Power & Transportation Company will construct a power plant on Snake River ten miles south of here.

POCATELLO.—Mr. William S. Cone is now superintendent of the American Falls Power, Light & Water Company's plant in this city. The company also lights Blackfoot, American Falls and Rexburg.

ILLINOIS.

CANTON.—The People's Gas & Electric Light Company expects in another year to change over to a 60-cycle, direct-current system.

CHICAGO.—Mr. J. F. Foster is now superintendent of the lighting plant operated by the South Park Commissioners at 57th Street and Cottage Grove Avenue.

FAIRBURY.—Improvements are being made in the equipment of the plant of the Fairbury Electric Light, Heat & Power Company, which include the installation of a 120-kw. generator.

CHICAGO.—The incorporation of the Madison Electric Company is reported. Among the incorporators are Messrs. E. J. Ryan and John Felker. The company's capital is $2500.

MOUND CITY.—The Mound City Water, Light, Power, Heat & Manufacturing Company has completed the erection of its new boiler house and the installation of four new boilers therein. The equipment is to be still further increased next year by the addition of a new engine.

MEREDOSIA.—Messrs. C. M. Skinner, J. W. Skinner and T. D. Beeley have filed articles of incorporation for the Meredosia Light, Heat & Water Company. The company is capitalized at $20,000 and was organized for the purpose of operating a heat, light and power plant.

EAST ST. LOUIS.—Articles of incorporation have been filed by the Illinois Illuminating Company, having a capital stock of $50,000. Messrs. C. E. Harris, George F. McNulty and E. G. Bruckmann are the incorporators. The corporation is to furnish light, heat and power for East St. Louis, St. Clair and Madison counties.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

PARIS.—The Paris Gas, Light & Coke Company has been absorbed by the Paris Gas & Electric Company, which recently filed articles of incorporation with a capital of $150,000. The officers of the latter company are: President, A. A. Boyd, of Michigan City, Ind.; vice-president, W. J. Hunter, Paris; secretary, Frank Garretson, Michigan City; treasurer, J. E. Parrish, of this city. The gas, heating and electric light plants will be remodelled and improved at once.

HAMILTON.—The Hamilton Light & Power Company, just organized, has secured the contract for the city lighting, current being supplied to 17 2000-c.p. city arc lights on a moonlight schedule and to 500 16-c.p. commercial incandescents, the latter receiving a 24-hour service. The company has not as yet its own power station, power being obtained from the Keokuk Light & Power Company, of Keokuk, Iowa. The capital stock is $10,000 and the officers are: President, R. R. Wallace; vice-president, R. D. Manson; secretary, treasurer and manager, J. A. Gordon.

EFFINGHAM.—The Effingham Electric Light & Power Company announces its intention to entirely rebuild its plant within the next six months. The plans have not been fully developed yet, but they include an alternating-current generator of 225 horse-power capacity, a Corliss engine, boilers, a superheater, condenser and transformer, also from 56 to 60 500-volt alternating-current series lamps.

INDIANA.

LOGANSPORT.—The city has appropriated $30,000 to be spent in improving the lighting plant here.

INDIANAPOLIS.—A franchise for lighting the downtown streets of the city has been granted to the Merchants' Heat & Light Company.

ROCKVILLE.—Mr. E. G. Lanning has been superintendent of the Rockville Electric Light Works since June 1, having succeeded Mr. E. Newkirk.

LAFAYETTE.—The Merchants' Electric Light Association, of this city, has placed an order for a new 150-kw. alternator to be installed at its electric light plant.

NEW HARMONY.—The city has purchased the plant of the New Harmony Electric Light Company, in consideration of $7000, and appointed Mr. Thomas J. Phillips superintendent and general manager.

LOGANSPORT.—A large electric power plant is to be erected in this city by Denis Uhl and others at a cost of $150,000. The plant will be operated by water power, necessitating the construction of a dam in Eel River.

TERRE HAUTE.—The city's present contract with the Terre Haute Electric Company expires February 15, 1905, and the council has instructed the Board of Public Works to advertise at once for bids for a new electric lighting contract.

IOWA.

ST. ANSGAR.—Two new 85-h.p. boilers are to be installed soon in the lighting plant here.

WEST POINT.—The citizens have voted for the establishment of a municipal lighting plant at an estimated cost of $4000.

FARMINGTON.—Mr. Charles Cleave is manager and superintendent of the Farmington municipal electric lighting plant. It has been decided to install new arc lamps for the street lighting.

KANSAS.

COLUMBUS.—The Columbus Electric Company announces that it is preparing to embark in the steam heating business in a small way. The plans will be perfected shortly.

TOPEKA.—The Edison Electric Illuminating Company is making a one-story brick addition to its engine house. The building is to cost $6000 and will be completed by October 15.

KINSLEY.—Mr. H. P. Ketelson, proprietor of the electric light plant of this place, writes that the number of lights being supplied by the incandescent circuit has been increased recently from 750 to 1000.

HUTCHINSON.—The following are the present officers of the Hutchinson Water, Light & Gas Company: President and manager, W. E. Hutchinson, Boston; vice-president and secretary, George A. Lewis, Boston; treasurer, J. W. Hamer, Philadelphia; chief engineer and eelctrician, James Holt.

KENTUCKY.

LEBANON.—A new electric light and power plant is to be installed here.

FRANKLIN.—Mr. E. E. Kirtley has succeeded Mr. W. H. Isbell as chief engineer and electrician of the Franklin Electric Company's plant.

LOUISVILLE.—When the generating station on the great Ohio Falls, near this city, is completed it will furnish more power than any other single plant. Two hundred thousand horse-power will be generated and distributed to Cincinnati, Evansville, Indianapolis and Louisville.

DANVILLE.—Mr. Frank T. Snyder, representing St. Louis capitalists, has been granted a franchise by the City Council to construct an electric light and power plant. He has also secured a franchise for a street railway and will run an interurban line from Danville to Junction City along the Shelby City pike.

LOUISIANA.

AMITE.—The Amite Light & Power Company recently purchased the electric light plant here and is making extensive improvements and enlargements. High-tension equipment is to be installed as soon as the new building is completed, with the expectation of supplying lighting current to Independence seven miles below here and Tongipohoo, ten miles above, as well as the smaller towns intervening. The system when completed will include ice, light and water plants. C. S. Stewart is president; D. H. Hull, vice-president and manager, and F. T. Mayer, secretary and treasurer.

MARYLAND.

CUMBERLAND.—The water board has appointed Ernest J. Laughlin superintendent of the city electric light plant, to succeed F. P. Lawler, who recently resigned.

BALTIMORE.—Subway Engineer Phelps submitted a report to Mayor Timanus showing the estimated cost of a municipal plant for supplying light, heat and power to the City Hall, the court house, the new docks and piers and Center Market space. He estimates the total cost of the plant at $175,000, and states that it would have sufficient capacity to light the parks as well as the public buildings, the docks and market places.

SALISBURY.—The incorporators of the Wicomico Electric Power Company met in Salisbury and organized with the following officers: Thomas Perry, president; Charles R. Disharoon, vice-president; W. S. Gordy, Jr., secretary; H. L. Brewington, treasurer; W. J. Staton, James T. Truitt, E. A. Toadcine, M. A. Humphreys, J. D. Price, Dr. Samuel L. Graham, of Salisbury. The charter granted at the last session of the Legislature was very liberal, the limit of capitalization being $2,000,000.

HIGHLANDTOWN.—The Baltimore County Water & Electric Company is a consolidation of the Chesapeake Electric & Water Company, Catonsville Water Company and the Towson Water Company. The company lights Highlandtown, Catonville and vicinities, and also supplies light to Relay, St. Denis, Paradise, Irvington, Olla and Orangeville. The company is capitalized at $300,000 and has the following officers: President, Martin Myerdirck, first vice-president, John W. H. Geiger; second vice-president, William S. Speed; treasurer, secretary and manager, Albert H. Wehr; superintendent and chief engineer, S. W. Cooper, and chief electrician, E. G. Rush. The company has under way the installation of a new alternating-current incandescent arc lighting system.

MASSACHUSETTS.

TAUNTON.—The current for the new electric lights which have been installed throughout the J. R. Williams stove lining plant will be supplied from the municipal electric lighting plant.

FRANKLIN.—Mr. George Batchelor has been elected president of the Union Electric Light Company, and Mr. E. L. Blanchard is superintendent. Mr. L. C. Lincoln continues as secretary, treasurer and manager.

LENOX.—A meeting of the Lenox Electric Light Company has been held and the following officers were elected for the ensuing year; President, William D. Curtis; vice-president, Henry Sedgwick; secretary, William G. Clifford; treasurer and water commissioner, Mr. Isaac J. Newton.

CHESTER.—Mr. Leroy Gardner is proprietor of the electric light plant which is operated under the style of the Chester Electric Light Company. The plant has been in operation since 1899 and Mr. Gardner now contemplates increasing its generator and storage capacity in order to meet the additional demand for lights.

BROCKTON.—The Edison Illuminating Company of Brockton has been authorized to issue 1000 shares of additional capital stock at $100 per share. Half of the proceeds will be used to pay off the debt incurred by additions to the plant and the other half will be devoted to the purchase of the plant of the Whitman Light & Power Company.

GREENFIELD.—The Greenfield Electric Light Company has petitioned the Board of Gas and Electric Light Commissioners for an increase of $35,000 capital stock necessary to complete the construction of the large concrete dam and power station on the Deerfield River, the entire cost of which will probably amount to about $125,000. About 1200 horse-power will be developed at the dam, which will probably be sufficient except during a few of the driest weeks in summer, during which period auxiliary power will be obtained from a steam plant.

CLINTON.—In about a year from now the work of building the Wachusett dam will have been completed and there will then be no further use for the power plant now located just across the town line in Boylston. It was suggested at a recent meeting of the Board of Trade that the plant could be made available as a source of power for Clinton industries. The plant is advantageously situated on a spur track already laid from the Central Massachusetts Railroad and it is said that 2000 horse-power could be developed. The plant was installed six years ago to furnish power for the use of the contractors at the quarry and dam, and when their work is completed it is probable that the plant can be purchased very reasonably. The matter will be considered further and its possibilities for utilization thoroughly investigated.

MICHIGAN.

DETROIT.—The Economy Heating & Lighting Company has been incorporated with a capital of $5000.

PENTWATER.—Mr. B. C. Lindley is manager of the plant of the Oceana Electric Company, of this city.

ANN ARBOR.—Mr. A. N. Richardson is superintendent of the plant of the Washtenaw Electric Company.

EATON RAPIDS.—The work of constructing the new electric light plant, for which bonds have been issued, will begin soon.

STURGIS.—Mr. E. B. Gray is purchasing agent and superintendent of the city lighting plant, and Mr. Charles Sprester is chief engineer and electrician.

KALAMAZOO.—The contracts recently awarded for the improvements to be made at the municipal lighting plant include a 400-h.p. engine, 90-light dynamos, boiler, condenser and shafting; also a new switchboard, new piping and 300 enclosed arc lamps. The total cost of the work is estimated at $20,661.

LANSING.—The Platt Power & Manufacturing Company has been organized with a capital of $500,000 to improve the water power in Lansing and extend the heating mains. The company also recently acquired the title to the Dimondale water power. It is proposed to transmit this power to Lansing to be used in connection with the power plants here.

SHELBY.—The council has been considering the advisability of either shutting down the municipal

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

electric lighting plant or raising the rates so as to put the plant on a self-supporting basis. It was thought that the outcome of the matter might be the issuing of bonds for the installation of a complete new plant, the present one being inadequate to supply the needs of the village, but this proposition was defeated at an election held for the purpose of deciding the question.

MACKINAC ISLAND.—The Board of Public Works is considering the question of purchasing the water, light and sewerage systems now in operation here. The plant was installed three years ago under the administration of ex-Mayor Bailey at a cost of $108,000, and it was decided at the time that the city should not operate the plant. If the board reports favorably to the council, the matter will be submitted to the people at a special election to be held soon.

MINNESOTA.

MONTEVIDEO.—The electric light plant is installing water-power long-distance transmission lines.

PELICAN RAPIDS.—Mr. C. M. Guy is superintendent and chief electrician of the village lighting plant.

SOUTH STILLWATER.—Mr. Walter Hill has been appointed superintendent of the new electric lighting plant at this place.

FARIBAULT.—The Polar Star Electric Company expects to install very shortly a 150 or 200-kw. generator at its power plant.

STARBUCK.—A new engine is about to be intalled in the municipal lighting plant. Mr. A. H. Dreyer is manager of the plant.

THIEF RIVER FALLS.—The contract for erecting the electric lighting plant here has been awarded to Mr. Carl Bartelson for $2755.

BARNESVILLE.—Mr. L. H. Clark is superintendent and manager of the municipal lighting plant, and Mr. H. H. Pierce is chief electrician.

WINTHROP.—A special election has been held, at which it was voted to issue $7000 bonds for extending the water mains and enlarging the electric light plant.

ST. PAUL.—The St. Paul Gas & Electric Company has been granted a franchise to extend its electric service to Lexington; also to St. Anthony Hill district, this city.

HALLOCK.—Articles of incorporation for the Hallock Light Company have been filed by Edward McVean, P. H. Konzin and others. The company is capitalized at $15,000.

BAGLEY.—Messrs. Kolb & Bohmer, who established an electric light plant here a few months ago, are erecting several blocks of new line and will install some new street lights. They have also secured additional contracts for lighting fifteen residences.

STILLWATER.—The Stillwater Gas & Electric Light Company contemplates making large extensions to its local system. Mr. E. L. Hospes has been re-elected president of the company, and Mr. R. S. Davis has been made secretary and treasurer, succeeding Mr. Otis Staples as secretary and Mr. George Mayer as treasurer.

MISSISSIPPI.

GREENWOOD.—Mr. A. L. Dabney has been elected manager of the water works and electric light plant in this city.

OXFORD.—It has been decided by the Town Council to issue $8000 worth of bonds to establish a new electric light plant.

MACON.—It is reported that all bids have been rejected for the $42,000 bond issue to be used in securing a new water works and electric light plant.

WOODVILLE.—The citizens by an almost unanimous vote have declared for an additional issue of $7500 in bonds for the construction of an electric light plant and water works system.

SENATOBIA.—The municipal lighting plant, which has been in operation since May of this year, is in charge of Mr. F. W. Funk as superintendent.

GREENWOOD.—The city has just purchased the plant of the Citizens' Light & Water Company, of which Mr. C. E. Wright was manager. Bonds to the amount of $15,000 were issued for the purpose.

MERIDIAN.—The new fireproof power house being erected by the Meridian Light & Railway Company is nearly completed. The company is laying several miles of 60 and 70-lb. rails to replace the old 35-lb. rails, and is constantly extending its lighting circuits.

PURVIS.—The Purvis Light & Power Company has been recently organized with the following officers: W. H. Magee, president; J. W. Woodward, vice-president and general manager; C. V. Hathorne, secretary and treasurer. The purpose of the corporation is to operate an electric light plant, a local telephone system and water works and manufacture ice. Orders for the machinery for the electric light plant have been placed.

GREENVILLE.—Mr. E. J. Lentz, superintendent and chief electrician of the Delta Electric Light, Power & Manufacturing Company, writes that extensive and costly improvements are being planned by the company. These will include a $30,000 addition to the main generating plant and the construction of an interurban electric road from this city to Leland, a distance of nine miles. The cost of the road and the necessary additional equipment is estimated at $150,000. The company's lighting circuit comprises 6000 lamps.

SARDIS.—The Panola Electric Light & Power Company has established a light and power station here to furnish light to this city, Batesville and Como. Transmission lines will be built to Batesville, eight miles distant, and to Como, seven miles away. The equipment will include a 100-kw. 60-cycle two-phase alternator, a 138-h.p. automatic engine, four 25-kw. step-up and step-down transformers, two series alternating current arc light systems of 15 lights capacity each, besides other supplies necessary to complete the equipment.

MISSOURI.

WELLSVILLE.—Mr. E. F. McBroom's lighting contract with the city has been renewed for five years.

CANTON.—The new municipal plant for the town of Canton is now in operation. It has cost the town about $16,000. Mr. W. S. Peters is chief engineer and electrician.

ST. JOSEPH.—It is stated that between $6000 and $7000 can be saved to the city in operating expenses of the electric lighting plant if the present antiquated machinery is discarded and modern equipment installed in its place. The citizens have voted for a bond issue of $75,000 to be used in building and equipping a new plant.

TRENTON.—The Trenton Gas Light & Power Company has recently rebuilt its plant and is now operating fifteen motors. The company also has under construction, one mile south of here on Grand River, a new 500-h.p. water power plant, in which turbine wheels will be installed. This plant will cost $50,000 and it is expected to be completed by December 1, 1904.

CARUTHERSVILLE.—The Caruthersville Ice & Light Company is capitalized at $25,000, with the following officers: C. B. Faris, president; H. C. Schult, vice-president; J. F. Franklin, secretary; W. A. Ward, treasurer; J. S. Wahl, manager; B. F. Colter, chief engineer; D. C. Acuff, chief electrician. The company has the city lighting contract, which includes ten 1200-c.p. arc lights at $100 per lamp per year and 100 32-c.p. incandescent lights at $24 each per pear; also six commercial arc lights and 2500 commercial incandescent lights.

MONTANA.

FORT HARRISON.—Bids for installing an electric lighting system have been advertised for, also current for lighting.

MISSOULA.—The Missoula Light & Water Company states that in 1905 a steam plant will be constructed at a probable cost of $25,000.

FORSYTH.—J. E. Edwards has been granted a franchise for the construction of water works and an electric light plant.

BOZEMAN.—It is reported that the Gallatin Water Power Company has been incorporated with a capital stock of $150,000 for the purpose of establishing a power plant at Sheep Rock, on the West Gallatin River. Messrs. George Cox, E. J. Carter and E. W. King are among the directors.

NEBRASKA.

VERDIGRIS.—Mr. M. Gruenberg is manager of the Verdigris Electric Company's plant.

CLARKS.—The electric lighting plant here has been destroyed by fire; the loss is not known.

LINCOLN.—Mr. George H. Morse has been awarded the contract for the construction of the lighting plant for this city, for which $65,000 bonds were issued a few weeks ago.

NEW HAMPSHIRE.

DERRY.—Mr. Harry L. Bartlett has resigned his position with the Derry Electric Light Company to engage in business for himself. He is prepared to do all kinds of wiring and electrical work for parties who may need his services.

NEW JERSEY.

LONG BRANCH.—The Consolidated Gas Company of New Jersey has been consolidated with the Long Branch Gas Light Company and the Long Branch Electric Light Company.

JERSEY CITY.—The incorporation is reported of the Conchas River Power Company, with an authorized capital stock of $25,000. Among the directors are J. E. Kelly and G. E. Griswold.

NEWTON.—The Newton Gas & Electric Company announces that its electric station is being entirely remodelled. A complete three-phase system will be installed, the power to be furnished by gas engines operated from a producer plant.

HAMMONTON.—The Hammonton & Egg Harbor City Gas Company is reported to have purchased from the Atlantic County Electrical Company the electric lighting plant here. The new owners will merge the lighting and gas plants on West End Avenue and expend $16,000 in building a power house and installing new machinery.

HADDONFIELD.—Engineers have reported upon municipal water works and an electric lighting plant for this borough, the plants to be operated jointly and to be constructed at a total approximate cost of $125,000. The proposition, however, has as yet only reached the stage of full discussion, and it may be some months before the construction is authorized.

NEW YORK.

SPENCERPORT.—Various improvements are under way at the electric lighting plant in this place.

ELMIRA.—The Elmira Water, Light & Railroad Company has recently added to its equipment a 1500-h.p. gas engine.

BUFFALO.—The Buffalo General Electric Company has increased its capital stock from $2,400,000 to $5,000,000, and will double the capacity of its plant.

CAMDEN.—A site has been selected for the municipal electric light plant and plans and specifications are being prepared. Bids will soon be advertised for.

ONEIDA.—The Madison County Gas & Electric Company is a consolidation of the Onedia Light & Power Company, Oneida Gas Light Company, J. W. Warner's plant and the Canastota Electric Light & Power Company. The company's authorized capital is $300,000. Mr. C. W. Koiner, of this city, is superintendent and chief engineer.

ALBION.—The Albion Electric Light, Power & Gas Company has elected the following officers and directors for the ensuing year: President, Bird W. Spencer; vice-president and general manager, W. C. Johnson; treasurer, L. H. Tyng; secretary, S. T. Church; who, with Hon. Frank A. Dudley, William Young and Frederick W. Cole, form the board of directors.

AMSTERDAM.—The following are the officers of the Amsterdam Street Railway Company, which owns the Amsterdam Arc Light Company and the Edison Electric Light & Power Company: President and manager, J. L. Hees; vice-president, S. H. Shotwell; secretary and treasurer, G. M. Place;

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

purchasing agent, J. N. Shannahan; chief electrician, T. Pettingill.

NEW YORK CITY.—The Miller Electric Company, with offices at 16 William Street, this city, has filed articles of incorporation with a capital stock of $100,000. The incorporators are Alexander A. Miller, August J. Miller and Edward H. Scattergood. The concern will engage in the manufacture and sale of electric light, heat and power for public and private use.

PORTCHESTER.—The New York & Westchester Lighting Company has been incorporated with a capital stock of $250,000 to operate in New York City, Yonkers, New Rochelle, Mt. Vernon and the towns and villages of Westchester County. The directors are named as follows: Cortland Betts, Morristown, N. J.; Fred N. Gilboyl, Brooklyn; Joseph E. Freeman, New York City. The Westchester Lighting Company has been absorbed by the new concern, which is said to be controlled by the Consolidated Gas Company of New York.

LYONS.—At the annual meeting of the Wayne County Electric Company, held recently, the following officers were elected: President, Dwight P. Chamberlain; vice-president, Charles A. Lux; secretary and treasurer, William H. Akenhead. The following-named gentlemen compose the board of directors: John Dunn, Jr., F. C. Eddy, C. D. Beebe, H. H. Crowell, James W. Putnam, Charles A. Lux and Dwight P. Chamberlain. The annual report of the treasurer as presented showed a substantial dividend to have been earned the past year.

NORTH CAROLINA.

ROCKY MOUNT.—The municipal lighting plant is in charge of Mr. A. S. Lyons, as superintendent and manager.

GREENSBORO.—We have been informed that the Cape Fear Power Company will soon move its offices from this city to Fayetteville, N. C.

MAXTON.—The Carolina Electric Company will probably remove its plant to a point about three miles from its present location in order to secure cheaper power.

WILMINGTON.—Mr. R. W. MacRae is chief engineer of the plant of the Wilmington Consolidated Railways, Light & Power Company, and Mr. R. M. Hunt is chief electrician.

BURLINGTON.—Mr. O. P. Dickenson is superintendent and chief electrician of the municipal lighting plant which was installed here a few months ago, Mr. R. E. Andrews being chief engineer.

NORTH DAKOTA.

PARK RIVER.—A new condenser is being installed at the municipal lighting plant, of which Mr. R. G. Wieland is superintendent and chief engineer and electrician.

OHIO.

XENIA.—The Xenia Heat, Light & Power Company is preparing plans for a central heating and electric light plant.

LONDONVILLE.—Mr. John D. Dyerman is manager and superintendent of the municipal electric lighting plant.

HICKSVILLE.—The Hicksville Electric Light Company is considering the installation of another direct-current dynamo.

ANTWERP.—Mr. Henry Harris is the proprietor of the local electric lighting plant. Mr. J. P. Lubbs is chief engineer and electrician.

COLUMBUS.—An ordinance is said to have passed the council providing for an issue of bonds for erecting and completing the electric light works in this city.

ATHENS.—The plant of the Athens Gas Light & Electric Company is reported to have been sold to and succeeded by the Athens Municipal Electric Light Company.

GARRETTSVILLE.—Messrs. A. W. Green, W. B. Martin, O. J. Martin and others have filed articles of incorporation for the Forde Lighting Company, fixing the capital stock at $25,000.

SIDNEY.—The Citizens' Light & Power Company has filed articles of incorporation with a capital stock of $150,000. Mr. G. T. Spahr and Mr. A. Dobbie are named among the directors.

ZANESVILLE.—An ordinance has passed the City Council, granting a franchise to the Southeastern Ohio Railway, Light & Power Company to erect poles and string and maintain lines of wire for conducting electricity to be used for heat, light and power.

OREGON.

GRANT'S PASS.—The Middle Fork Electric Company has been organized here for the development of power on the Middle Fork of the John Day River. Mr. R. C. Reese, of Dixie Meadows, is president of the company.

MOLALLA.—Mr. F. P. Hurst of the Molalla Power & Irrigation Ditch Company has secured the right to appropriate water from the Molalla River for the operation of an electric plant to furnish Canby, Hubbard, Woodburn and other valley towns of Oregon with light.

TOLO.—The Medford & Condon Water & Power Company has its new plant in operation with a present capacity of 800 horse-power, to which 6000 horse-power will be added. The company is furnishing a motor service for mining and irrigation purposes and has secured lighting contracts for Medford, Grant's Pass and Central Point. The lighting and power circuits include forty miles of transmission line. The officers of the company as as follows: President and general manager, C. R. Ray; secretary, E. R. Ray; superintendent and chief engineer, J. D. Alsup; chief electrician, J. K. Soden.

PENNSYLVANIA.

SPRINGFIELD.—The Springfield Electric Light Company, with a capital stock of $5000, has been granted a charter.

DERRY STATION.—Mr. George Mowry is now president of the Derry Electric Light Company; Mr. D. Keit, vice-president; Mr. D. Brown, secretary and manager.

EAST LANDSDOWNE.—It is reported that Philadelphia capitalists are promoting an enterprise for the installation of steam heat and electric light plants in this territory.

SOUTH FORK.—The following-named gentlemen are the officers of the South Fork Electric Light, Heat & Power Company: W. I. Stineman, president; J. C. Stineman, secretary and treasurer; Alex. M. Cover, superintendent; William Rebaugh, chief engineer.

NORTHUMBERLAND.—The Borough Council has adopted a resolution to submit to the taxpayers at the election to be held November 8 the proposition to vote on issuing bonds to the amount of $15,000 for the purpose of building a municipal electric light plant for the borough.

NEW KENSINGTON.—The New Kensington Electric Light, Heat & Power Company is officered as follows: G. B. Ingham, president; Thomas M. Conville, secretary and treasurer; B. J. Rarie, superintendent; John Spencer, chief engineer. The company also furnishes light to Parnassus.

PHILADELPHIA.—Mr. A. J. De Camp is manager of the Philadelphia Electric Company; Mr. H. C. Lucas is purchasing agent; Mr. W. H. Norris, chief engineer of motive power; William C. L. Elgin, chief electrician for the incandescent lighting system, and Mr. A. H. Manwaring, chief electrician of the arc lighting system.

YORK.—The commercial value of the great York Haven electric power plant is now being felt in York as well as in the coal regions. Not only are the local and suburban trolley cars being operated, but a large number of the largest manufacturing plants in the city are being run by means of the river power; it is said that the service is giving entire satisfaction to the manufacturers. The York Haven Corporation has also contracted with the Edison Electric Light Company for the supply of the necessary current for lighting the city of York and private houses.

BEECHCREEK.—The Town Council has passed an ordinance granting to W. P. Mitchell, of Indianapolis, Ind., and N. J. Mitchell, for a corporation to be formed by them, the exclusive right for 99 years to establish a system of water works, electric lighting and sewerage. The water is to be taken from Cove Run, near Mapes, where a reservoir will be built. It is proposed to extend the water works to Blanchard. The electric lighting plan includes the furnishing of light to this borough, Blanchard and Howard. Work on the water system must begin before April 1, 1905, and be completed by Feb. 1, 1906. Two years are given for the completion of the electric light system and 3 years for the system of sewerage. It is stated that the persons interested will at once form a company and apply for a charter.

SHENANDOAH.—The People's Light, Heat & Power Company, of Mahanoy City and Shenandoah, has purchased the ground and the title of the leased land owned by the Hooven Mercantile Company, situated on East Railroad Street, Mahanoy City. Work on the erection of the plant will begin at once as most of the contracts were awarded several weeks ago. At the same time a force of men will be put to work erecting the line between the two towns, taking in the surrounding places. The plant will have an initial capacity of 1000 horse-power supplied by two 500-h.p. direct-connected dynamos, and provisions will be made for doubling this output.

RHODE ISLAND.

NARRAGANSETT PIER.—The Narragansett Pier Electric Light & Power Company states that it is proposed to abandon the present power plant, which, however, will be left intact for the present. Current will be purchased from the Sea View Railroad Company and distributed on its primaries at 2000 volts. The lines are now being placed in condition for this increased voltage. Enclosed arc lamps will be installed and operated on a three-phase system at 60 cycles. Other improvements will also be made.

SOUTH CAROLINA.

BATESBURG.—Mr. Frederick Minshall, of Abbeville, has been awarded the contract for the construction of the electric light plant and system of water works, for which the city recently issued bonds to the amount of $20,000.

COLUMBIA.—The Columbia Water Power Company, which does a power business only, furnishes current to the Columbia Electric Street Railway, Light & Power Company. Mr. Frank P. Carpenter, of Manchester, N. H., is president of the company; Mr. Frederick S. Anabar, Boston, Mass., secretary; Mr. Alvin F. Sortwell, Cambridge, Mass., vice-president and treasurer; Mr. W. M. Shannon, this city, superintendent and chief engineer and electrician.

TENNESSEE.

GREENVILLE.—Mr. H. Reeves, who is proprietor of the local electric light plant, is arranging to install 25 new 6-ampere alternating-current enclosed arc lights with regulators.

KNOXVILLE.—Work has begun on the plant of the Knoxville Power Company, which will be constructed on the head waters of the Little Tennessee by New York capitalists, and in which R. W. Austin, of Knoxville, is interested. The probable cost of the work is $100,000. Mr. John Bogart, of New York, is the chief engineer.

CHATTANOOGA.—Local press reports state that the city of Chattanooga will not build the proposed "suck" power plant. The right as vested in the act of Congress, which was approved by President Roosevelt, April 28, now goes to J. C. Guild, C. E. James and associates, whom, it is reported, will at once take steps to erect the proposed lock and dam power plant to be erected.

TEXAS.

QUANAH.—Mr. E. A. Clousnetzer owns and operates the electric light plant of this city.

CLEBURNE.—L. W. Dunne and associates are reported to be interested in the construction of an electric light plant and street railway at Cleburne.

JACKSBORO.—The electric light plant here is now operated under the style of Hensley Brothers, they having consolidated the Jacksboro Light & Power Company with Hensley & Latimer.

BROWNWOOD.—The Boysen Light & Power Company will probably install within the next few months a 150-kw. alternator and a new Corliss engine. Mr. F. Hall is superintendent of the company's plant.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

LULING.—Mr. F. Zedler is president of the Luling Electric Light & Power Company; Mr. H. Zedler, vice-president; Mr. F. A. Heise, secretary; Mr. Charles Zedler, treasurer; Mr. Oscar H. Stair, manager, superintendent and chief engineer and electrician.

COMMERCE.—The following are the present officers of the Commerce Electric Light Company: President, Mr. T. W. Thompson; vice-president, Mr. W. B. De Jeanett; secretary and treasurer, Mr. J. D. Jernigan; manager and superintendent, Mr. C. E. Randle.

VERMONT.

BELLOWS FALLS.—The following officers have been elected by the Fall Mountain Electric Light & Power Company: President, W. A. Russell; treasurer, P. H. Hadley; manager, L. J. Royce; chief electrician, D. W. Connors.

RANDOLPH.—The White River Electric Company, which holds the city contract for electric lighting, obtains its power from the Bethel Electric Light & Power Company, of Bethel, Vt. Mr. F. H. Ketcham is manager and superintendent.

VIRGINIA.

NEWPORT NEWS.—The Consumers' Light, Heat & Ice Company, of this city, is in the hands of a receiver and the plant is closed, probably permanently.

CULPEPER.—The Culpeper Electric Light Company, composed of Dr. O. Nalle and G. F. Major, is considering the addition of an 8-ton ice plant to its present electric plant.

WASHINGTON.

ABERDEEN.—The Aberdeen Electric Company has sold its property, plant and franchises to the Gray's Harbor Electric Company.

RITZVILLE.—C. O. Green, who owns the Ritzville Electric Light Company, is preparing to install a sub-station at the corner of H and Second Streets.

FOREST.—It is reported that Harry West has secured control of the water power of Hylack Mill for a term of fifteen years and will proceed at once to construct a lighting plant to be operated by means of the power developed at the mill.

MENATCHEE.—Mr. Charles F. Keiser is superintendent of the Menatchee Electric Company's plant. The officers of the company are: President, Mr. Arthur Gunn, who is also manager; secretary, Mr. Charles F. Brown; treasurer, Mr. L. M. Marr.

WEST VIRGINIA.

KEYSTONE.—Mr. G. J. Evans is manager of the plant of the Keystone Light & Power Company, of which Mr. John Evans is superintendent.

MORGANTOWN.—The following are the present officers of the Union Utility Company, which is a consolidation of the Morgantown Electric Light & Traction Company and the Morgantown Electric Light & Power Company: President, I. C. White; vice-president, Davis Elkins; secretary, George C. Sturgess; treasurer and manager, H. R. Warfield; superintendent and chief engineer and electrician, W. S. Ingram.

WISCONSIN.

LAKE GENEVA.—The Equitable Electric Light Company announces that it will extend its lines around Lake Geneva within the coming year.

BALDWIN.—Mr. E. J. Core is owner and manager of the local lighting plant, and Mr. S. F. Core is secretary and chief engineer and electrician.

JANESVILLE.—The Janesville Electric Company furnishes heat, light and power to the city of Janesville, Wis., and operates three generating plants for this purpose. The central or main station is located at Janesville on the bank of Rock River and is equipped with both alternating and direct-current machinery, the direct-current machines being used for the street railway and the larger part of the motor and incandescent lighting loads, while the alternating current generator, in conjunction with the Monterey plant, situated 1½ miles down the river, and the Fulton plant, located 12 miles north of the Yahara River, supply the smaller portion of the incandescent and motor load and the series alternating arc lamps used for street lighting. The machines are driven from a central shaft, which derives its power primarily from water wheels, but steam is also provided as a safeguard against low water or possible injury to the turbines. The central plant is being replaced by a new station, which is located farther up the river, and to which the old machinery will be transferred. The building is to be constructed on the Palmer system, using concrete blocks. The forebay is about 75 feet wide and the center of the measuring gates are approximately 40 feet from the wall of the penstocks. The engine room is 80 feet long by 55 feet wide and has an equipment which should take care of any breakdown that might occur. The direct-current portion consists of six machines. Six turbines are to be used in all; four of them will be 56-inch Samson turbines, while the other two are 72-inch Leffel wheels, which are used at present in the old central station. These turbines are arranged in pairs, two being placed in each penstock, and are so connected to the shaft by jaw clutches that two, four or the entire six may be used at the same time. The company furnishes current for 250 motors with capacities ranging from ¼ to 30-h.p., and the day load is oftentimes heavier than the peak night load. The new plant when completed will be one of the most modern installations of its size in the State.

CANADA.

ST. JOHNS, QUE.—Mr. S. Fletcher is superintendent of the plant of the St. Johns Electric Light Company.

COWANSVILLE, QUE.—The Cowansville electric light plant is now owned and operated by Mr. Nelson Buzzele.

MONTREAL, QUE.—Mr. R. M. Wilson is superintendent of stations for the Montreal Light, Heat & Power Company.

BRANTFORD, ONT.—The Brantford Electric & Operating Company, Ltd., is contemplating installing a new steam plant.

REGINA, MAN.—Mr. J. A. Johnston is manager of the municipal electric light plant of this city, which was established in April of this year.

PERTH, ONT.—The Canadian Electric & Water Power Company announces its intention of installing meters and will abolish the present flat-rate system.

PORT ARTHUR, ONT.—The town authorities are making arrangements to install a new alternator and a 500-h.p. water wheel in the municipal lighting plant. Mr. T. H. McCaubry is manager and superintendent of the plant.

VANCOUVER, B. C.—The British Columbia Electric Railway Company, which furnishes lighting current to this city, New Westminster and Victoria, has acquired the business and plant of the Vancouver Gas Company and announces a reduction of 20 per cent.

PRESTON, ONT.—The taxpayers of the town have decided in favor of municipal ownership of the electric lighting plant. A by-law has been carried to raise the sum of $27,000 to purchase the existing incandescent plant and the arc system now owned by private individuals. A new power house will be erected and a first-class plant will be installed.

CHILLAWACK, B. C.—The Chillawack Power & Light Company, now seeking a municipal franchise, purposes spending $100,000 in developing electric energy for power and lighting purposes. Surveys are being made on the Chillawack River and the general plans for the development of the property which the company has acquired have been determined upon.

SUSSEX, N. B.—The Sussex Water & Electric Company has been absorbed by the Sussex Manufacturing Company, which also controls the William Howes Foundry Machine Shop and the Ross & McPherson Woodworking Company. Mr. S. H. White is president; Mr. G. H. White, vice-president and manager; Mr. H. B. Price, secretary and manager, and Mr. C. D. Mills, chief engineer and electrician.

KINGSTON, ONT.—The city recently took over the plants of the Kingston Light, Heat & Power Company at a cost of $182,000, and they will hereafter be operated as municipal utilities. Mr. John M. Campbell, an electrical expert, has been engaged to investigate the condition of both the gas and electric plants, and the city will make such extensions and alterations as may be necessary to make them thoroughly efficient. It is estimated that about $100,000 will probably be spent in improvements. Manufacturers have been notified of the discontinuance of the flat rate for the present; new rates will be made later on.

WINNIPEG, MAN.—A company has recently been organized here, under the name of the Manitoba Water-Power Electrical Company, with a capital of $5,000,000, for the purpose of establishing a power plant at Silver Falls on the lower Winnipeg River. The officers are: H. J. McDonald, former premier of the province, president; Daniel McMillan, governor of Manitoba, vice-president, and R. L. Roblin, the present premier, secretary and treasurer. The company expects to have the plant in operation in two years and to be able to deliver power to manufacturers at half the present cost of steam. The current will be transmitted a distance of forty miles. About $100,000 has already been spent in development and engineering work.

TORONTO, ONT.—E. J. Davis, Commissioner of Crown Lands, is stated to have turned over to E. W. Backus, of Minneapolis, Minn., president of the Backus-Brooks Company and of the Koochiching Company, the final papers granting full and exclusive water power rights on Koochiching Falls on the Ontario-Minnesota international boundary. The plans of dam construction submitted by Engineers Wallace and Fanning have been approved, subject to the survey of the government engineers. The plans provide for a dam to raise the waters of Rainy River to high-water mark. The dam will produce a fall of about 32 feet, and will develop about 30,000 horse-power, the total cost of the work being estimated at about $500,000. Office of the company is in the Andrus Building, Minneapolis, Minn.

MEXICO.

ARANDAS, JALISCO.—It is reported that the state authorities have granted permission to Porfirio Torres Camerenas, of Guadalajara, to construct and operate an electric lighting plant in this town. The electricity will be generated by means of steam.

TEPIC, TEPIC.—Advices state that a company has been organized by Alfred Lonergan, Cristobal Villanuena and Estiridon Ramirez, all of Ixtlan del Rio, this state, for the purpose of building an electric light plant in this city. The cost of the plant is estimated at $40,000.

AMECA, JALISCO.—Mr. Aurelio Reyes, of Guadalajara, who operates an alcohol factory in this city, has entered into a contract with the City Council for the establishment of an electric light and power plant here. The plant will be operated in connection with the alcohol factory and will cost about $20,000.

TORREON, COAHUILA.—At a recent meeting of the board of directors of the Compania de Tranvias Electricos, of this city, it was decided to endeavor to merge that company and the Torreon Electric Light Company into one concern. It is proposed that the same plant shall furnish power for lighting the city and operating the new electric street railway here.

PUEBLA, PUEBLA.—Miguel M. Navarro, of Mexico City, is said to have obtained a concession from the Government for the construction of a water power plant on River Les Molinos, districts of Atlixco and Cholula, this state. The right to use 3000 liters of water has been secured. The concessionaire has pledged himself to begin work within the next six months.

IXTLAN DEL RIO, TEPIC.—The City Council has entered into a contract with Messrs. Ugarte and Garcia Fuentes, of Guadalajara, for the establishment of an electric light and power plant in this city. The contract calls for 20 arc lights and 800 incandescent lights. It is the intention of the contractors ultimately to secure power from the falls of Elojo de Agua, situated about forty miles from the city.

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

American Electrician.

Vol. XVI. New York, November, 1904. No. 11.

THE ELECTRICAL EQUIPMENT OF A MODERN TYPE FOUNDRY

PLANT OF THE AMERICAN TYPE FOUNDERS' COMPANY AT COMMUNIPAW, N. J.

The American Type Founders' Company has recently established a central plant for the production of printing type at Communipaw, N. J., in which electricity is used exclusively for power and lighting purposes. The main building is a three-story fireproof structure, having a frontage of 200 ft. on Communipaw Avenue, with two 190-ft. wings extending backwards. These wings are connected by two one-story bays which are separated by courts. The buildings were planned with a view to obtaining all the light possible so that they are bountifully supplied with large windows, as some of the illustrations will show. The bays, which contain the type-casting machines, are provided with glass skylights in addition, so that a good distribution of light may be obtained for these important machines. The general lay out is such that extensive additions may be made should future occasion require it.

The power generating plant, which is capable of furnishing all of the power needed in the entire works, both for motors and for electric lighting, is installed at a point on the shop grounds about 200 feet north of the main group of buildings; and from here electric current and steam are delivered to the various buildings through conductors and pipes located in a covered trench. The equipment of the power plant, both mechanical and electrical, is fully in keeping with the character of the building in which it is housed, not only with respect to the thoroughly high grade character of the apparatus, but also to the completeness of detail manifested in the installation. The structure is of brick and is fireproof. It is 150 ft. long by 50 ft. wide, and is divided by brick partition walls into three equal sections consisting of a smelting-room, engine-room and boiler-room, which, owing to the lay of the ground, are arranged step fashion; the boiler-room floor being about 6 ft. below the engine-room floor, and this in turn being slightly lower than the smelting-room floor. This arrangement, while made of necessity, possesses many advantages.

Some of the most noticeable features of the power-house are the abundant supply

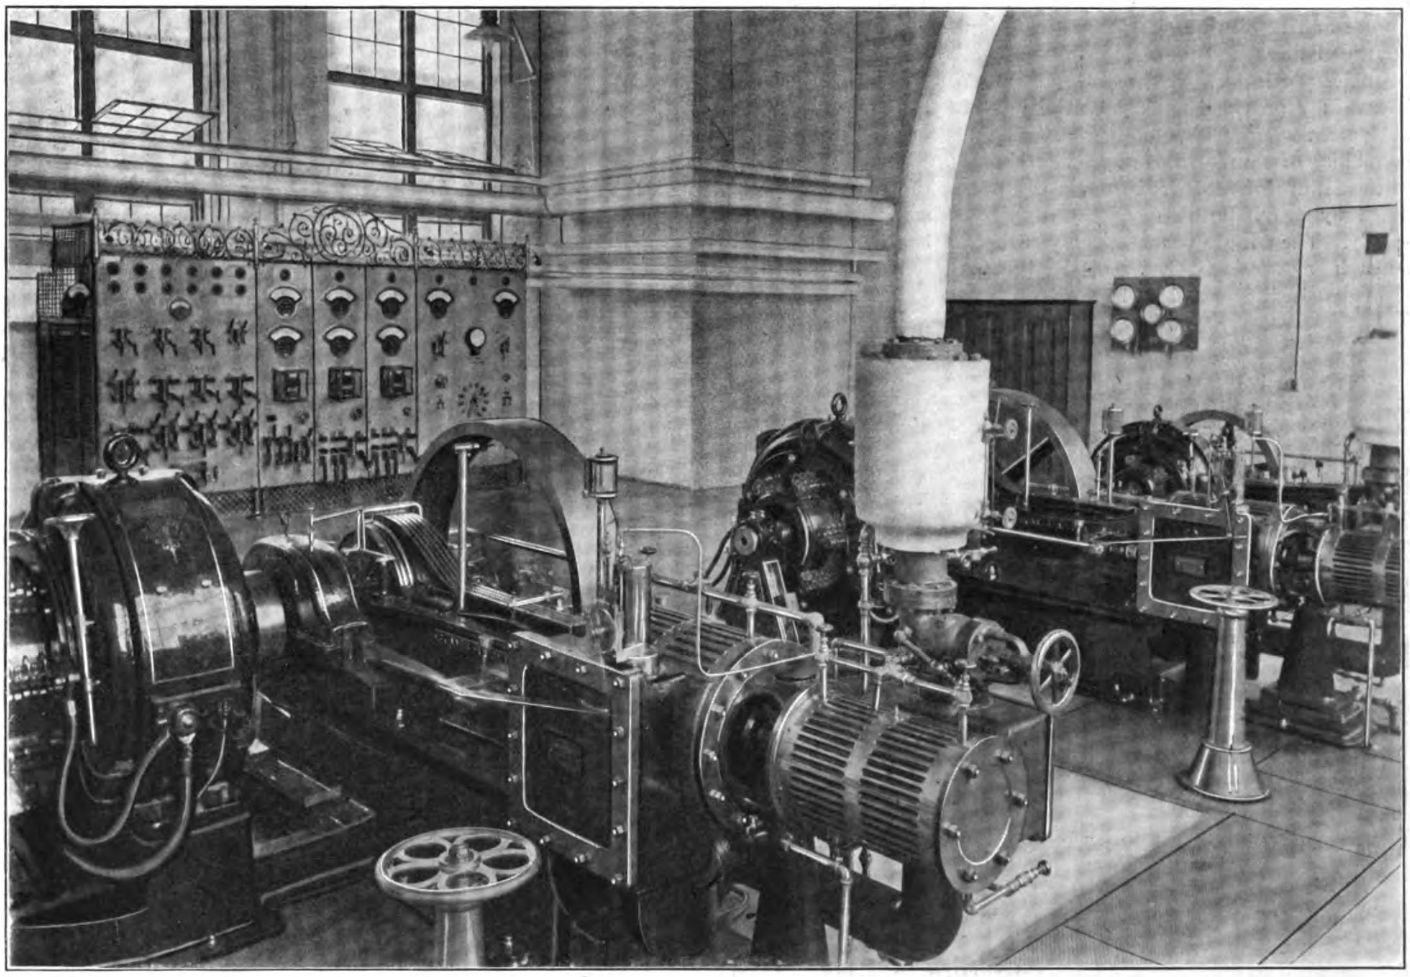

FIG. I.—GENERAL VIEW OF ENGINE ROOM IN POWER HOUSE OF AMERICAN TYPEFOUNDERS' COMPANY.

of daylight and excellent ventilation and the convenient arrangement of all the apparatus. A coal pocket is built outside the power-house with openings into the boiler-room, and the fuel is carted and dumped into the pocket from above. The site is hard by the Jersey Central Railroad tracks, and in time it is hoped that a spur will be built from the road to the coal pocket so that coal will be delivered direct.

The boiler equipment consists of two 150-h.p. Heine water-tube boilers, which are equipped with "Tread-kill" rocking grates made by M. H. Treadwell & Co., of New York, and with improved Argand blowers made by The McClave-Brooks Co., of Scranton, Pa. The usual water columns, feed and blow-off connections, gauges, injectors and safety valves are provided. The smoke breeching delivers into a radial brick chimney 5 ft. in diameter and 100 ft. high, the draught being governed by an automatic Kiely damper regulator placed in the flue. The boilers are hand-fired with buckwheat anthracite coal. Space is provided for the future installation of additional boilers.

Care and taste were shown in the design of the boiler feed and blow-off piping. Troublesome leakage at the blow-off valves is carefully provided against by the use of the patent surface blow-off cocks, and the possibility of shutdown of any boiler owing to the failure of feed-water supply is eliminated by providing two sources of water supply. The feed-water pumps deliver through a 500-h.p. Cochrane feed-water heater built by the Harrison Safety Boiler Works, of Philadelphia, Pa., and thence to the boilers. The connections provided in the feed-water system are very flexibly arranged. There are three pumps provided, one of which may be used as a fire pump. These are all of the Deane duplex type, 7½ and 5 in. by 6 in. They are located conveniently for access in the open space in the boiler-room between the boilers and the engine-room partition. The feed-water heater is located to the left of the pumps. Fig. 3 shows the admirable arrangement of the pumps and connections. The necessary valves are provided for using the pumps interchangeably and for by-passing the feed-water heater should this be necessary. Water is usually taken from the city water mains, but a storage tank of 6000 gallons capacity is provided in addition. A muffler and grease separator is installed in the boiler-room and connected in the exhaust line. Exhaust steam is used for heating, the line being provided with a back pressure valve; but live steam may also be used if required, connections being provided for the purpose through a reducing valve.

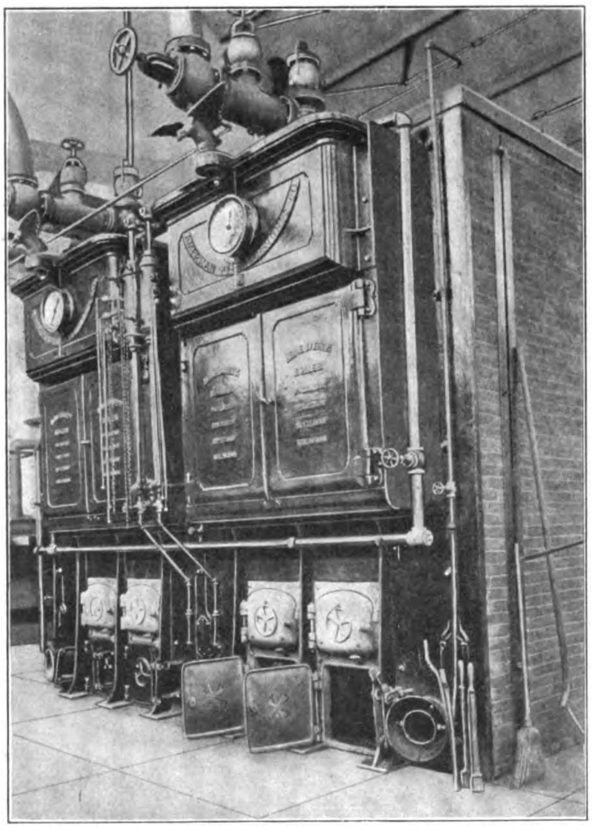

FIG. 2.—VIEW OF BOILERS.

Steam is delivered from the boilers at 135 lbs. pressure through 10-in. copper bends to a single main boiler. Drainage is provided for by a Cochrane separator which bleeds to a Bundy steam trap. To the main header in the boiler room an 8-in. main is connected which runs along the side of the engine-room. This main is controlled by a gate valve. Steam is delivered to the engines through 3½-in. copper bends, each engine being provided with a separator above the steam chest and a gate valve as shown in the leading illustration. The separators are connected to a common return pipe leading to a steam trap, and the low pressure drips on each engine feed to the blow-off tank, check valves being provided on each engine drip.

The exhaust valve of each engine is controlled by a stand and handwheel located on the floor to one side of the cylinder as shown by Fig. 1. The line runs in a covered trench in the floor. Drainage is carefully provided for in the entire system of steam piping as well as at the engines. Condensation is, however, minimized throughout the entire plant by non-conducting coverings on all steam piping which are, in addition, covered with heavy canvas and painted. The auxiliary steam piping for the pumps, etc., is taken direct from the boilers through valves situated directly behind the main valves. The steam piping and boilers were installed by the Blake & Williams Company, of New York City.

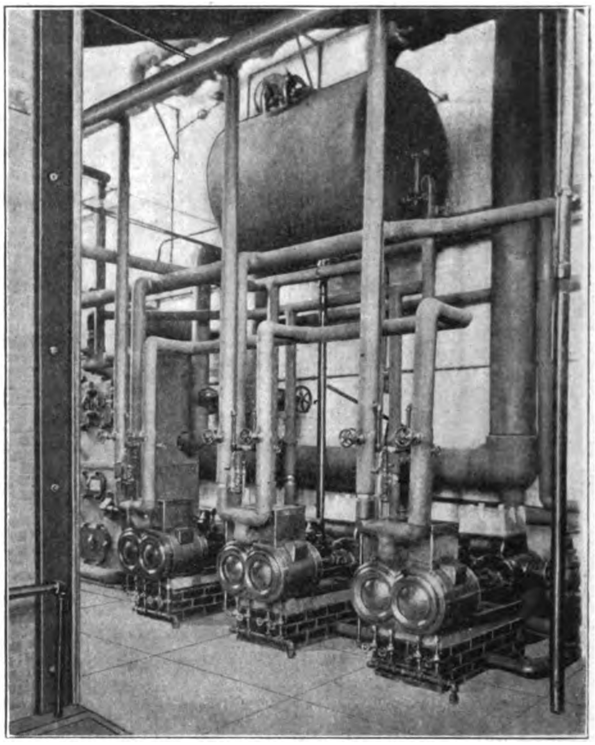

FIG. 3.—FEED-WATER PUMPS AND AUXILIARIES.

The generating equipment consists of three direct-connected units. Two of the engines are tandem-compound of 125 h.p. each, built by the Skinner Engine Company, of Erie, Pa.; the other is a 60-h.p. Woodbury engine, built by the Stearns Manufacturing Company, of Erie, Pa. An automatic oiling system is provided, and the engine cylinders are provided with snifting valves and are drilled and tapped for indicator connections. The engines are operated non-condensing and are provided with the usual centrifugal fly-wheel governor. The generators are all of C & C make, two being of 75 kilowatts capacity, and the other of 30 kilowatts capacity. They are compound-wound machines and generate an e.m.f. of 125 volts. A gauge board is provided on the wall of the engine-room as shown in Fig. 1, containing two high-pressure steam gauges, a low-pressure steam gauge, a recording steam gauge and a clock.

The switchboard is a beautiful five-panel board of 2-in. marble built by the F. A. La Roche Company, of New York, and installed by the Tucker Electrical Construction Company. It is 19 ft. long and stands 8½ feet high, the panels being of a uniform height of 7½ feet and surmounted with an ornamental copper grill. The arrangement of the panels from left to right is as follows: One 5-ft. distributing panel, three 3-ft. generator panels and one 5-ft. storage battery panel. The distribution panel has 12 pilot lamps in a double row across the top, four 50-ampere circuit-breakers, three 400-ampere circuit-breakers, one 150-ampere circuit-breaker, four 800-ampere circuit-breakers, and one 1000-ampere, double-pole switch for connecting the street service should this become necessary. The voltmeter shown in the center of the panel is of the double-reading type, serving also as a ground detector. It is controlled by a push-button switch. The three generator panels are all equipped alike. Each panel has a pilot lamp, Empire voltmeter and ammeter, Thomson integrating wattmeter, field rheostat, plug for parallel connection, one 750-ampere double-pole switch, one 750-ampere single-pole switch and one 750-ampere circuit-breaker. The storage-battery panel has three pilot lamps, Empire voltmeter and double-reading ammeter, one 150-ampere battery circuit-breaker, one 30-ampere circuit-breaker for the booster motor, one Bristol recording voltmeter with a 25-ampere double-throw switch, one 25-ampere circuit-breaker, one 200-ampere double-pole main switch for battery charge and discharge, one 100-ampere motor switch and a ten-point end-cell switch. A swinging differential voltmeter is mounted on a bracket on the left end of the board and is used for coupling the generators in parallel. A rear view of the switchboard is shown by Fig. 5. From this it will be noted that all of the instruments excepting the recording meters are set in the back of the board and have dials illuminated by incandescent lamps from the rear. The connections are neatly and securely made, all of the wiring being enclosed in Circular Loom. The cables from the battery are brought into an iron pole box fastened to the wall, and from there to the switchboard. The cables from the generators are brought across the floor in conduit to the rear of the switchboard, and from the point where they leave the conduit to the lugs on the board they are heavily corded and painted. Upright busses convey the current from the switches to terminals at the top of the board, distribution cables starting here and crossing over to an iron pole box whence they run to the main buildings in a covered trench.

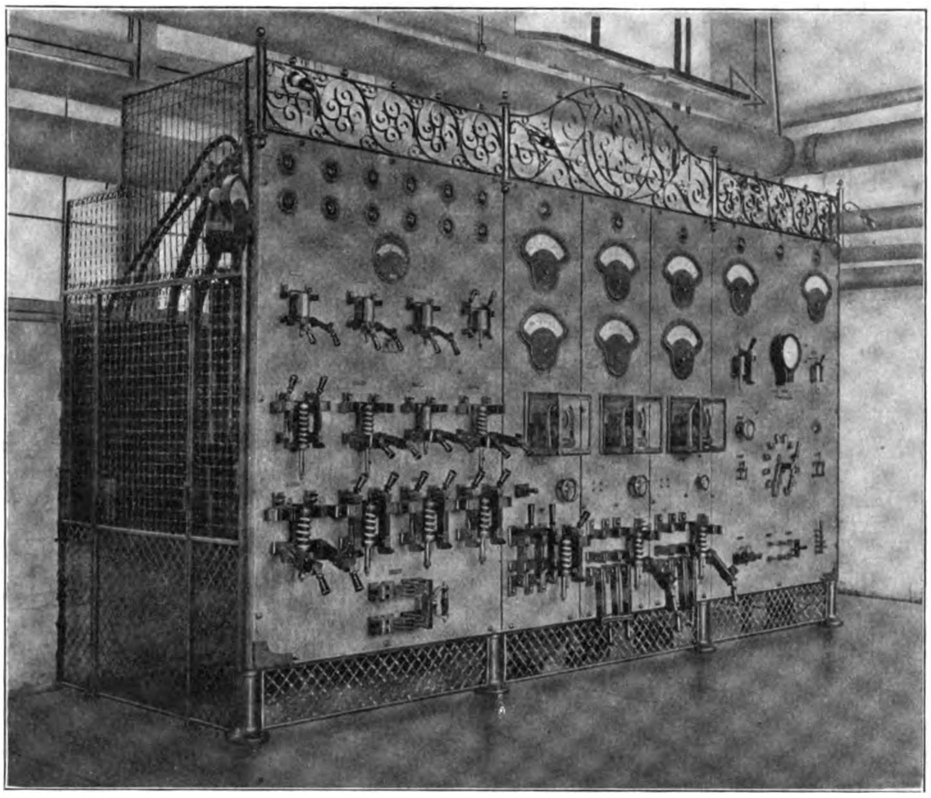

FIG. 4.—FRONT VIEW OF SWITCHBOARD.

In one corner of the room is a small motor-generator made by the Electro Dynamic Company, of Philadelphia, Pa. This is used for charging the battery, the motor operating at 120 volts and 45 amperes and the generator delivering 50 amperes at 60 volts. The battery is of standard make and is composed of 70 Chloride cells, having a capacity of 125 ampere-hours.

The general electrical distribution is on the two-wire system at 125 volts. All of the motors and also the lamps, both arc and incandescent, are supplied with current from the same bus bars in the power plant. The distances from the switchboard to the various points of current consumption are not great so that even with the maximum distance the e.m.f. generated is sufficiently economical, and it was preferable that no higher voltage be used for the sake of simplicity and safety. Only a few arc lamps are used and these are of the enclosed type. The greater part of the illumination is by incandescent lamps. There are in the neighborhood of 1500 drop lights provided, a lamp being invariably placed at each machine tool; whereas for general illumination clusters are used. All of the wiring throughout the buildings is in iron conduit. Leads are run from the various distributing boxes and each circuit feeds about ten lamps.

The main feeders are run from their respective switches on the distribution panel of the switchboard in the power-house through the covered trench to a terminal board in the building. There are six feeders in all, and there are 1,500,000 cir. mil lead-covered cables. In the trench they are suspended on hangers fitted with insulated iron sleeves. Each pair of cables connects to a five-switch panel forming part of the distribution board, and the panels in turn may be connected together with switches so that all six cables can carry the load if desired. The main board has marbleized panels with slate gutters and doors, the copper being highly polished. Fifteen main circuits controlled by as many fused switches furnish the light and power to the main buildings. Each circuit feeds a distribution box which in turn controls the local lighting and power mains. The panel boxes are constructed much in the same manner as the main board, the switches being provided with enclosed fuses and the copper being highly polished. The wiring for the motors is run in iron conduit, the starting boxes for individual motors being placed on the machine within easy reach of the operator as may be seen by reference to Fig. 10.

Fig. 6 is a view of the lower right wing of the machine shop. In this department the machines, being small, are group-driven from line shafting. There are two groups and each is belt-driven by a 5-h.p. G. E. motor mounted on a bracket with the starting box and panel directly beneath.

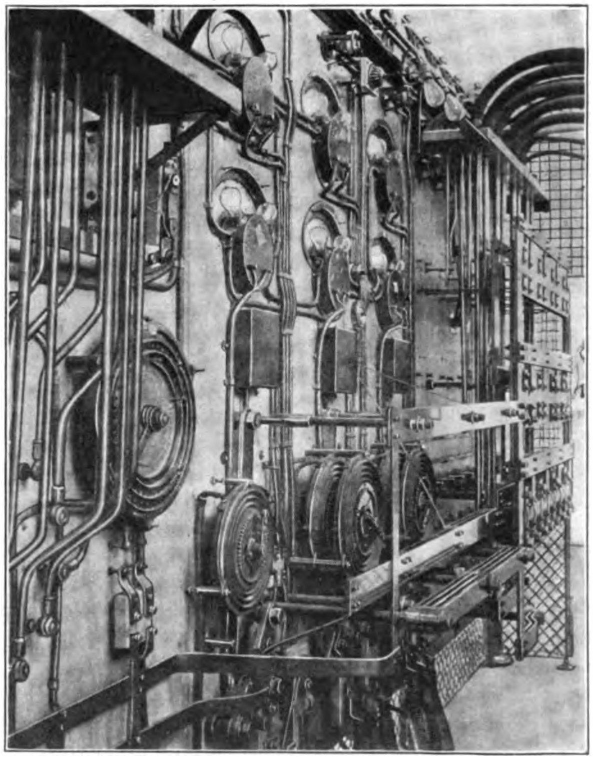

FIG. 5.—REAR VIEW OF SWITCHBOARD.

The bay immediately adjoining this wing

is shown by Fig. 7. Attention may be directed to the care displayed in running the wires and pipes in this bay. In the center of the bay, running the entire length, is a trench connecting with the main trench, and in this are placed electric cables, water pipes, compressed air mains and gas mains; the water, air and gas being used in the numerous type-casting machines in the bay. Four electric circuits are provided in the trench and each of these feeds seven panel switches. These panels have two fused switches each, and from them two circuits lead to floor-boxes from which wires run to the type-casting machines. A switch is provided on each machine with leads running to the starting box of the motor. Connections are also provided for the flexible metallic lamp fixture shown at each machine.

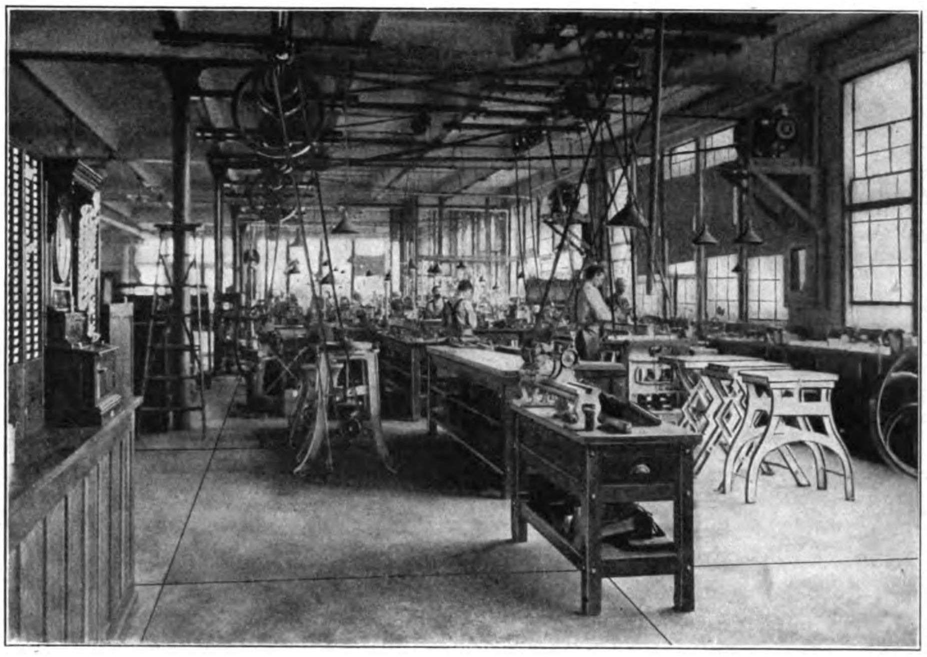

FIG. 6.—GENERAL VIEW OF MACHINE SHOP IN LOWER RIGHT WING.

The operation of type-casting machines has always been difficult owing to the excessive speed variations required. The size of type made by the machines varies all the way from a letter about 1-32 of an inch to an initial letter about 2½ in. wide. The speed of the machine must be regulated according to the size of type being cast, the pumping of metal, cutting, trimming and notching of the type requiring a longer period with large type than with the smaller sizes. The type-casting machines are equipped with Stow multi-speed motors, built by the Stow Manufacturing Company, of Binghamton, N. Y. The motors are back geared and the speed is varied through a wide range by the rheostat and the well-known method used in the Stow motors of changing the magnetic reluctance of the field. Two nicking machines, each driven by a ½-h.p. Holtzer-Cabot motor are also installed.

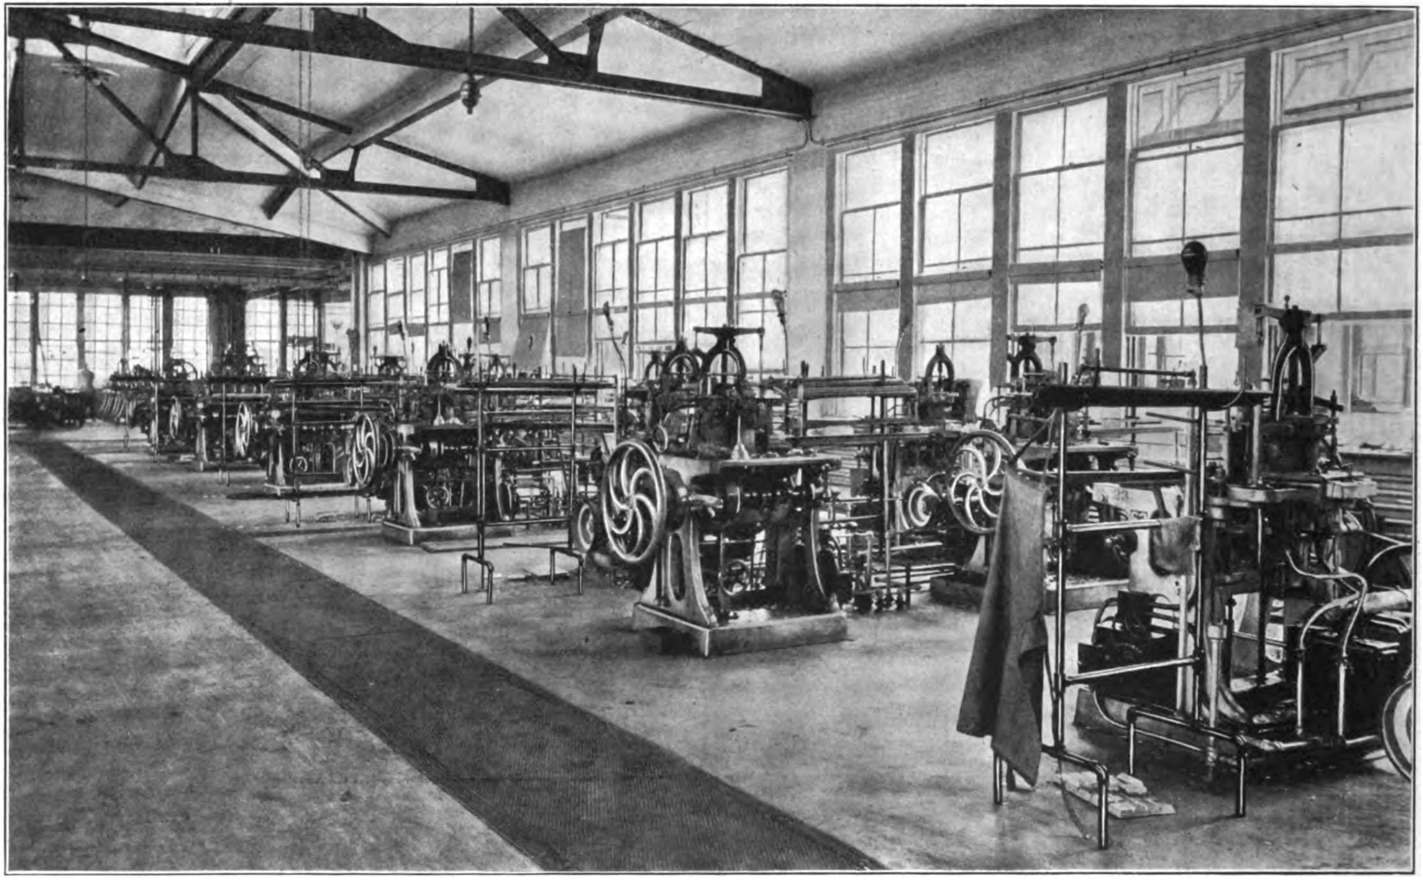

FIG. 7.—VIEW OF BAY CONTAINING TYPE-CASTING MACHINES.

The gas and compressed air are used to generate an intense heat for the crucibles containing the type metal. The compressed air is also used to clear the mould of any metal adhering to it after the type has been cast. A compressed air plant is installed in the right wing to supply this service. The equipment consists of two 8 by 10 Clayton compressors, driven through Renold silent chains by two 7½-h.p. G. E. motors. The compressors store in two large tanks from which the air is fed to the machines under a pressure of 10 pounds. The second bay is also equipped with type-casting machines; but these are of a larger size and require 2-h.p. motors.

The equipment of the engraving department on the second floor consists of eight Holtzer-Cabot motors driving as many engraving machines at 7200 r.p.m. The motors run at about 2500 r.p.m. and are belted to a small countershaft from which a small flexible shaft is driven at the high speed mentioned. The grinders used in sharpening the engraving tools are driven by small Eck motors.

The matrix fitting department contains nine matrix cutters. These are direct-driven by ⅓-h.p. compound-wound Sprague motors fitted with switches on top of the motor. The saws and routing machines in this department are also driven by 1-h.p. and ½-h.p. Sprague motors respectively; the former being direct-connected and the latter belt-driven.

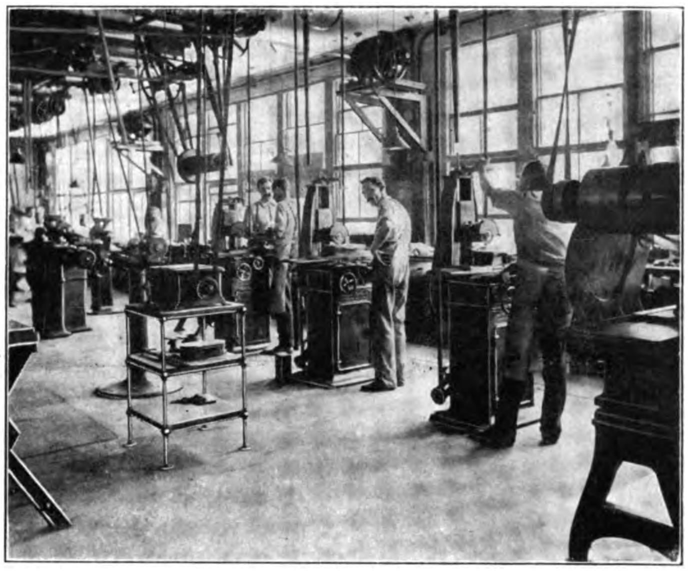

FIG. 8.—VIEW OF MOULD-MAKING DEPARTMENT.

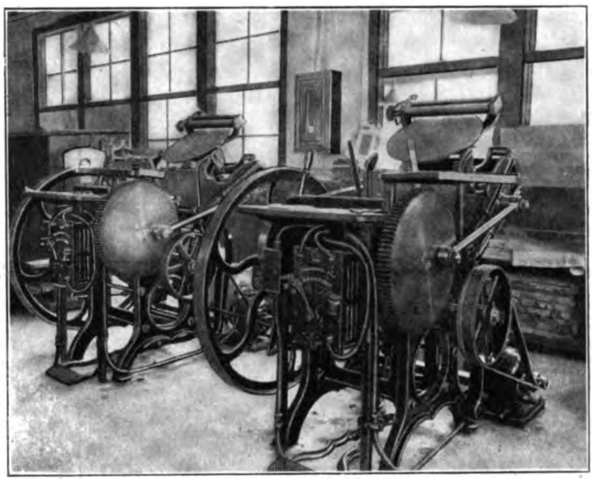

FIG. 10.—MOTOR-DRIVEN GORDON PRESSES.

Fig. 8 is a view of the mould-making department which adjoins the matrix-fitting department. The machines here, like those in the lower right wing, are group-driven by two 5-h.p. G. E. motors. A feature of this department is the magnetic chuck made by The O. S. Walker Co., of Worcester, Mass. One of these chucks is provided on each of the machines shown in the foreground of the illustration. There are four of these machines in operation, one large and three small, and they operate very satisfactorily. A Walker demagnetizer is also provided.

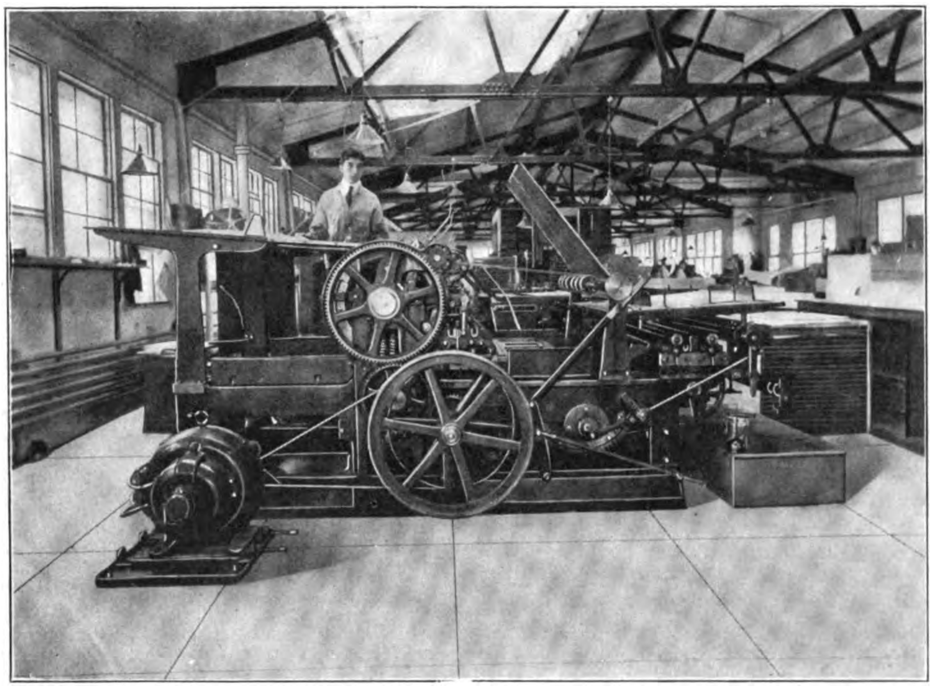

FIG. 9.—MOTOR-DRIVEN WHITLOCK CYLINDER PRESS.

On the third floor of the main building is the printing department. Here are installed five Whitlock cylinder presses belted to 3-h.p. Holtzer-Cabot motors as shown in Fig. 9. Each of these presses is provided with a no-voltage and push-button release starting box made by the Carpenter Enclosed Resistance Company, of New York City. The motor-speed controllers are of Cutler-Hammer make. Other equipment on this floor consists of two Universal presses belted to ½-h.p. Holtzer-Cabot motors; two Gordon jobbers belted to ¼-h.p. Holtzer-Cabot motors as shown in Fig. 10; two cutters belt-driven by 1-h.p. Holtzer-Cabot motors; one folder belted to a ½-h.p. Holtzer-Cabot motor; one stitcher and one saw, each belted to a ⅙-h.p. motor.

The main group of buildings has three electric freight elevators and three automatic dumb waiters. The freight elevators were built by the Marine Engine & Machine Company, of Newark, N. J., and are driven by Crocker-Wheeler motors. Two of the elevators have a lifting capacity of 6000 lbs., and the other has a capacity of 10,000 lbs., the speed of all three being 50 feet per minute. The smelting room, which forms part of the power-house, is equipped with an electric lift for elevating cars from the smelting-room floor to a track running from the smelting-room along the ground to the main factory. The two stirrers in this room are driven by a 5-h.p. G. E. motor through countershafting.

The plant has been in operation now for some time and has given every satisfaction. We take this opportunity to record our indebtedness to Mr. W. S. Marder for courtesies extended in the preparation of this article.

◆

PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION.

The Pennsylvania State Independent Telephone Association was organized September 27, at Harrisburg, Pa., by representative independent telephone interests. The following is the list of officers: B. F. Meyers, president; R. E. Flinn, vice-president; Charles Griffith, second vice-president; H. E. Bradley, secretary, and C. E. Wilson, treasurer. The executive committee consists of B. F. Meyers, C. E. Wilson, R. E. Umbel, E. D. Schade, C. W. Kline, J. G. Splane, W. D. Barnard, W. B. Trask and G. B. Rudy.

At the afternoon session held the next day, the following papers were submitted and read: "Long-Distance Service Equipment," by S. H. Browne; "Telephone Auditing," by I. D. Gindhart, Jr.; "Progress of Independent Telephony," by W. Scarlett; "Telephone Exchange Equipment," by C. Russell, and "Traffic Associations," by H. E. Bradley. In the evening a banquet was held at which many prominent independent telephone men made addresses.

FEED-WATER HEATING.

BY R. T. STROHM.

Three considerations demand that the feed-water, before being permitted to enter the boiler, shall be heated to a greater or less extent. Some plants may involve all three, and others only two. But for at least two good reasons the boiler feed-water should be passed through a preliminary heater. The first consideration is that of economy. Manifestly, it will require less heat to change a pound of hot water into steam at a given pressure than to convert a pound of cold water into steam of equal pressure. Consequently, each heat unit added to the water before it reaches the boiler is a gain, as far as the fuel consumption of the boiler is concerned. The saving which can be effected, therefore, is directly proportional to the rise in the temperature of the feed-water. The percentage of saving in fuel which may be secured by heating the feed-water is easily calculated, knowing the steam pressure and the initial and final temperatures of the water, by the use of the formula

$$k = \frac{100\,(t'' - t')}{H - t + 32}$$

in which

k = percentage of saving;

t'' = temperature to which the feed-water is heated;

t' = temperature to which the feed-water had formerly been heated;

H = total heat of the steam at the usual working pressure;

t = initial temperature of the feed-water.

For example, suppose that in a plant using water whose initial temperature is 60° F. and generating steam at 120 pounds gauge pressure the feed-water temperature should be increased from 140° F. to 210° F. The fuel saving would then be

$$k = \frac{100\,(210 - 140)}{1188 - 60 + 32} = \frac{7000}{1160} = 6\% \text{ nearly.}$$

This, it must be understood, it but the apparent saving, however. The actual net saving will be less, owing to the fact that it becomes necessary to deduct from the above an amount equal to the sum of the interest on the heater investment, the cost of repairs, and the depreciation loss.

The second consideration is that of safety. It is no longer a matter of doubt as to what effect cold feed-water has upon a boiler, especially one carrying high steam pressure. Engineers have come to recognize the fact that it is extremely poor practice to introduce comparatively cold feed-water into a boiler whose plates are at a temperature of from 100° to 200° higher than that of the water. The contraction and expansion set up, due to changes of temperature, hasten the deterioration of the shell and weaken it, by the well-known principle of fatigue of metals, and are contrary to all ideas of safety.

The third and last consideration is that of purification. It is this one which may exist only in occasional instances. The two foregoing reasons apply to every plant. But since feed-waters contain many impurities which no amount of heating will remove, purification by this means is possible only in certain instances. For example, if a feed-water contains carbonate of lime or of magnesia, heating it will serve to drive off the carbonic acid by which the carbonates are held in solution, thereby precipitating them. The sulphates may also be thrown down by heating to a temperature of nearly 300° F. If the feed-water contains acids, mud, grease or organic matter of various kinds, simply heating it will not purify it.

Boiler feed-water is heated by either or both of two methods. First, it may obtain its heat from steam, or it may absorb heat from the furnace gases after they have left the boiler heating surfaces. If steam is used for heating, it may be either live steam, taken direct from the boiler, or it may be exhaust steam from the engines, pumps and auxiliary apparatus, which might otherwise go to waste.

At first glance, it would seem impossible to gain anything by taking steam from a boiler to heat the feed-water for that boiler, except in the matter of purification and the prevention of stresses due to unequal expansion. The idea of a thermal gain, or saving of fuel, would seem preposterous, inasmuch as all the heat taken from the boiler would be returned thereto, neglecting radiation losses, leaving the heat balance just the same. Yet the actual economy of this method has been proved by the use of live steam heaters, and hence there must be some rational explanation of the apparent contradiction. The explanation lies in the fact that the hot feed-water is better able to absorb heat rapidly than the colder water, while at the same time the circulation is augmented, which further tends to increase the rapidity of heat transmission. The prevention of heavy scale formations also facilitates the heating and reduces heat losses.

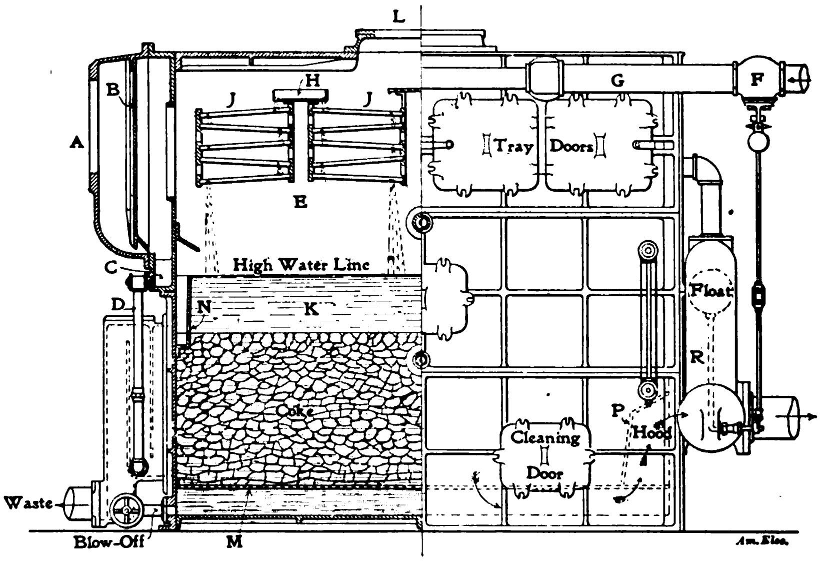

FIG. 1.

As commonly understood, a feed-water heater is a device which enables the heat of exhaust steam to be returned to the boiler, and by far the larger number of heaters are built for this purpose. If the heater is built to utilize the heat of waste furnace gases, it is termed an economizer. A live steam feed-water heater is usually spoken of as a purifier, because that is its main purpose, and so there is little or no likelihood of confusing these types of heaters.

Exhaust heaters, or more simply, feed-water heaters, are divided into two general classes, known as open heaters and closed heaters. In the former the feed-water is exposed to atmospheric pressure, being in contact with the outside air. In the latter there is no contact of feed-water and atmosphere, the water being enclosed in the heater and subjected to the pressure existing in the boiler, for which reason this class is frequently designated by the term "pressure heaters." There is no mingling of steam and feed-water in the closed heater. Each has its own path of circulation, heat from the steam being transmitted to the water through metal walls separating them.

Open heaters may be still further subdivided into two groups, known as direct-contact heaters and coil heaters. In the direct-contact open heater the exhaust steam is led into a chamber where it is mingled with a spray of water, heating the latter and condensing the former. This chamber is open to the atmosphere, which permits all uncondensed steam to escape. In the coil open heater a number of coils of pipe are arranged in an open tank or vessel, the exhaust steam passing through the coils and heating the feed-water which surrounds them.

A well-known type of direct-contact open heater is illustrated by Fig. 1, one half being shown in section and the other half in outside elevation. The heater proper is an approximately rectangular box built up of cast-iron plates securely bolted together, these plates being ribbed on the exterior surfaces to give the requisite strength. The exhaust steam enters at A, where it is immediately thrown against a vertical ribbed plate B which deflects the current and at the same time catches the particles of oil which come over from the engine cylinder. The oil and condensed steam then drip from the plate *B* into the pocket *C* and thence to the waste overflow through the drip pipe *D*. The steam being thus purified to a large extent, passes on into the condensing chamber *E*, where it meets the cold water supply. The water enters through the regulating valve *F* and the pipe *G*, the latter having two branches, one opening into each half of the heater. One branch, shown only in part, conducts a portion of the feed supply to the pan *H*, whence the water overflows and runs down upon the inclined trays *J*, *J*, which have serrated edges, and are alternately inclined at opposite angles, so as not only to break up the feed-water current into a number of thin sheets, but at the same time to give it a comparatively lengthy travel before allowing it to drop into the hot well *K*. A similar set of trays occupies the upper part of the other half of the heater, and they are supplied with water by the other branch of the pipe *G*. The steam, coming in contact with the thin sheets of water as they fall from tray to tray, rapidly heats the water, adding to the latter the condensation resulting. Any steam not condensed escapes by the outlet *L* to the atmosphere. The water thus heated falls to the bottom of the heater, which forms the hot well. In the lower part of this chamber is a perforated plate *M* which supports a thick bed of coke through which the hot feed-water must pass on its way to the boiler. The coke forms a filter bed which not only removes any impurities entrained by the incoming feed, but also catches the carbonates of lime and magnesia which have been precipitated by the heat of the exhaust steam. A skimming device *N* serves to remove all of the lighter impurities, such as oil and scum, which would float on the surface of the water, and discharges them into the waste pipe.

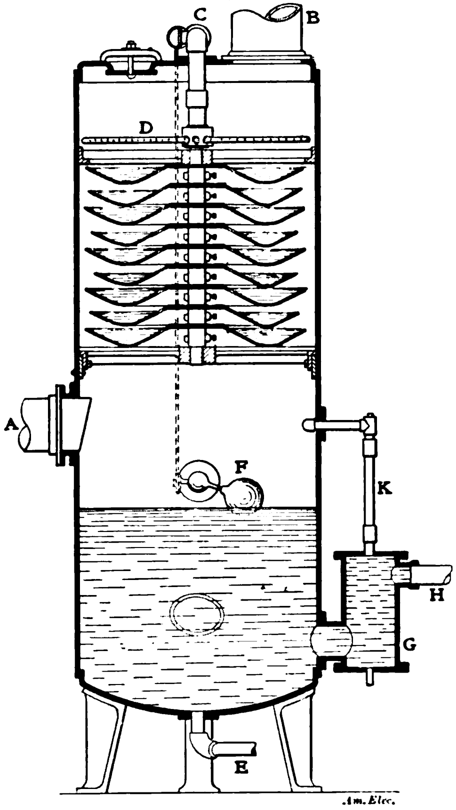

FIG. 2.

The purified feed-water, having reached the chamber beneath the perforated bottom, passes under the hood *P* into the pump suction chamber *R*, in which is a float regulating the supply valve according to the demands made upon the heater by the boiler feed pump. The hood *P* prevents the passage of any of the hot feed-water to the pump without first going through the filter bed. The heater is provided with a large number of cleaning doors by which entrance to the interior may be had, to remove the trays or to clean the inner surfaces.

Another type of direct-contact open heater is illustrated by Fig. 2. It has a cylindrical iron shell supported on legs, into which the exhaust steam is admitted at *A*, and from which all uncondensed vapor escapes at *B*. The cold feed-water enters through the balanced valve *C*, and passes thence to the distributer *D*, falling into the upper tray of the series contained in the top of the heater. The top pan or tray becoming filled, the water runs over its inner edge, falling to the tray below, filling the second and then flowing over its outer rim to the third, and so on. The incoming water is thus divided into a large number of thin sheets which rapidly absorb heat from the exhaust steam. The lower half of the shell forms a settling chamber, and is furnished with a blow-off valve *E* by means of which the precipitated impurities may be blown out at intervals. A float *F* regulates the rate of inflow of the cold water, the hot feed-water leaving the heater through the small cylinder *G*. The arrangement of this auxiliary cylinder is such that no oil can be pumped from the heater to the boiler. For, if the water level falls below the level of the suction pipe *H*, the pump will draw steam through the pipe *K*, breaking its action and preventing its taking any more water until the level rises.

The open heater of the coil class consists merely of a tank full of water in which is submerged a coil of pipe through which the steam is circulated. It is not a much-used form because of its low efficiency, but it is easy to construct when there is no possibility of obtaining a better, which is probably the only reason for its use.

A closed heater is shown in section by Fig. 3. In this type the water occupies the main part of the shell while the steam circulates through the pipes. The exhaust steam enters the heater at *A* and passes downward through the left bank of tubes until it reaches the closed chamber *B*. Here the direction of the current is changed and the steam ascends through the right bank of tubes to the outlet *C*. All condensation which results from the giving up of heat is collected in the chamber *B*, together with the oil carried over from the engine. These are removed by means of a trap connected to a drip pipe *D*. The feed-water enters at the lower connection *E*, flowing upward and across the heater to the outlet *F*, thus necessarily passing among the heater tubes. It will be noticed that the direction of flow of the water is directly opposed to that of the steam, which is the condition required for obtaining maximum feed-water temperature.

The tubes in this heater are given a bend at their lower ends, being expanded into a cast-iron plate at the top and into the roof-shaped cover of the chamber *B* at the bottom, this chamber forming the oil separator. The separator is thus suspended from the upper tube sheet by means of the heater tubes. The reason for this peculiar construction is to allow perfect freedom for contraction and expansion. One of the great problems in the design of tubular feed-water heaters is to obtain a form which will maintain tight joints and yet permit the expansion and contraction which inevitably follow changes of temperature. By the construction shown in Fig. 3 there is little or no restriction offered to either change of length or position of the tubes, so that no strains are set up which could loosen the joints and cause them to leak.

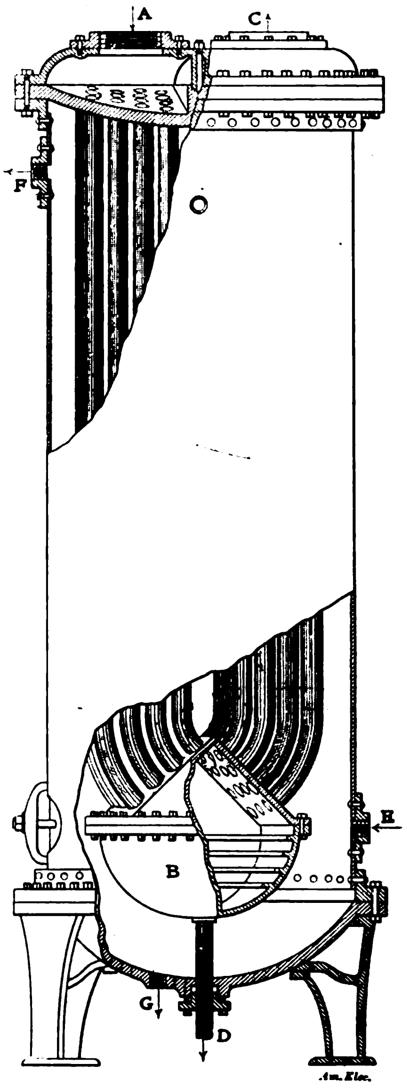

FIG. 3.

To prevent the steam current from picking up the oil from the bottom of chamber *B*, as it reverses in direction, the lower walls have a number of projecting baffles cast on them, which, by their downward slope, tend to check any upward movement of water or oil. Beneath the oil separator, and forming the lower end of the heater shell, is a hemispherical settling chamber in which the precipitated impurities collect and are removed by the blow-off pipe *G*. The drip pipe *D* is provided with a stuffing-box and gland, allowing vertical motion without leakage.

Another form of closed heater is illustrated by Fig. 4. It differs from the previous one in that the steam flows outside the tubes while the water flows through them. The shell is of cast-iron with a large chamber at each end. The water enters the lower one, *A*, in a direction almost tangent to the interior surface of the shell, instead of diametrically. The result is that the feed-water is given a whirling motion in the chamber *A*, making it practically certain that the water will rise through all the tubes in approximately equal amounts, a thing which might not happen if the water in the lower chamber were quiescent or nearly so. The tubes are corrugated, as shown, and are made of copper, being rigidly fixed into the upper and lower cast-iron heads of the heater. The corrugations offer sufficient flexibility to take up all expansion or contraction which may occur. At the same time they increase the effective heating surface and cause the water to be kept thoroughly agitated while flowing through them. The feed passes upward and out at *B*, while the exhaust steam entering at *C* passes downward and out at *D*. The usual drip and blow-off pipes are provided, at *E* and *F* respectively, while a relief valve is placed at *G*. Every heater through which water is forced on its way to the boiler should have a safety or relief valve on it to prevent damage in case the pump is started while the boiler feed valve is closed.

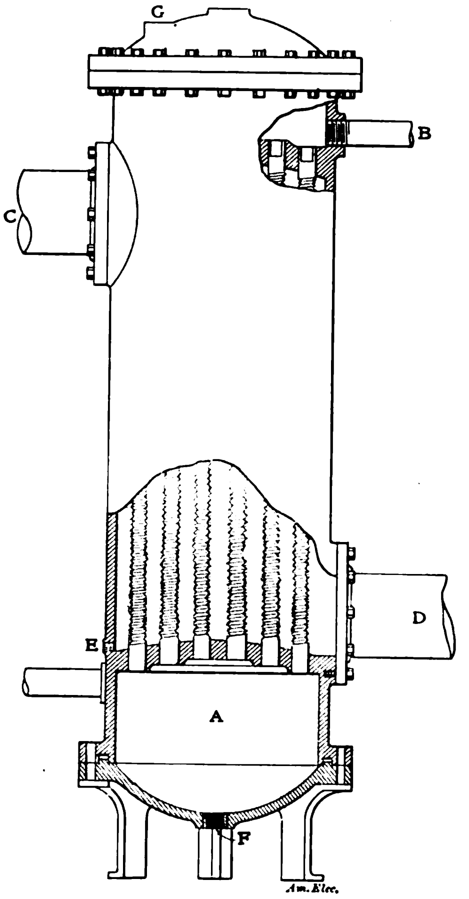

FIG. 4.

Still another method of making allowance for the expansion and contraction is to arrange the heater tubes in long coils made of seamless copper pipe, and fastened rigidly at their ends only, somewhat as in Fig. 5, the feed-water going in at *A* and out at *B*. The steam rises vertically through the heater from the inlet *C* to the outlet *D*. Iron rods, *E, E, E,* sustain the weight of the coils but do not hinder their lateral movement.

The reason for using copper pipe in many of these heaters is to obtain rapid transmission of the heat, inasmuch as the thermal conductivity of copper is much greater than that of iron, which means that one square foot of copper pipe will transmit more heat in a given time than a square foot of iron pipe, all other conditions being the same.

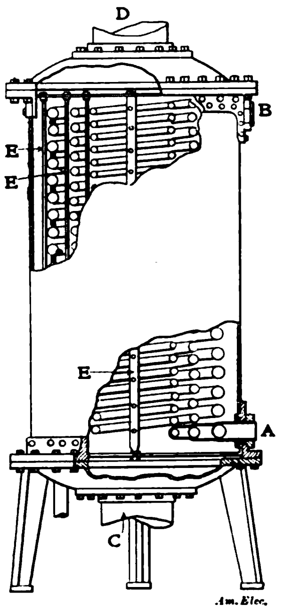

FIG. 5.

The economizer, which is a special form of feed-water heater, is radically different from the ordinary exhaust heater in its construction and operation, and hence will not be described in this connection. Indeed, the subject of economizers is quite extensive enough to warrant its treatment in a separate article.

◆◆◆

DISTRIBUTING SYSTEMS FROM THE STANDPOINT OF THEORY AND PRACTICE.

BY PHILIP TORCHIO.

Systems of distribution of electrical energy are classified into *direct systems*, which utilize directly, without transformation, the electricity furnished by the generating station; and *indirect systems*, which modify the intensity and potential of the current by means of secondary apparatus, such as transformers, storage batteries, etc.

The direct systems are adopted where the electrical energy generated is to be distributed in the immediate vicinity of the power station. Since the beginning of the early eighties it was, however, a recognized fact that on account of the prohibitive cost of transmission to great distances the direct systems alone could not give the solution of the general problem of economical generation of large amounts of power at a central point and economical distribution to distributing centers covering large areas, more or less distant from the station.

One of the first solutions which was suggested was the use of direct-current, high-tension transmission, feeding in series a number of electric storage batteries distributed at convenient points along the high-tension circuit. Each storage battery would independently, supply current to the local installation lamps. The limitations of this system were soon recognized, and its importance was lost when the alternating-current transformer was brought into the field.

The National Company for Distribution of Electricity by Secondary Generators, Limited, exploiting the inventions of Messrs. Gaulard and Gibbs, showed in 1884, at the Exhibition of Turin (Italy), a system consisting of a 30-h.p., 2000-volt, 50-cycle, single-phase alternator, feeding a single wire transmission circuit 48 miles long, having connected in series at different points along its route a number of transformers of the Gaulard and Gibbs type, feeding at different voltages through their secondaries a variety of incandescent and arc lamps.

Gaulard and Gibbs, recognizing as important that an alternating-current transmitting system should be capable of transforming alternating into direct current, devised a high-efficiency, direct-current, autocommutating machine, which was schematically a self-starting, single-phase, 50-cycle, rotary converter. Soon after the close of the Turin Exhibition of 1884, Messrs. Zipernowsky, Deri and Blathy developed the parallel type of transformer for connection in multiple arc, which was exhibited at the Budapest Exhibition of 1885.

The results obtained with the Gaulard and Gibbs transformers at the Turin Exhibition attracted the widest attention among engineers, and opened the way to classical laboratory researches and monumental discoveries in the field of application, which laid the foundation to all future developments. From this beginning it became apparent to the best engineers what was the line to follow in the development of the distribution of electrical energy.

Since 1884 great progress has been made in the applications of electricity, but it is remarkable that in no essential features have the systems as developed departed from the general lines conceived at that time.

There have been and there still are differences of opinion as to more or less important details, but the general idea set forth, of a single generating station transmitting high-tension current to centers of distribution, which is then transformed to lower potentials for supplying the translating devices, has been the keynote of all the later developments. The problem of distribution is at present narrowed down to the consideration of engineering and commercial features, which must now guide the engineer.

One of the main points to solve is, how to distribute the low-potential current to the translating devices? One is thus brought to face the selection of a system which will give the most satisfactory result, and to select between overhead lines or underground distribution, direct-current system or alternating current, and whether single-phase or polyphase system, and of two, three, four or five-wire distribution, the selection of the suitable voltage for translating devices and a number of other similar questions.

Now by defining any of these features one affects the whole system and gives a characteristic stamp to practically every piece of apparatus required for the generation, distribution and utilization of electric current. It is evident, therefore, that on account of the complexity of the problem the systems of distribution could not be studied from the standpoint of theory alone. One can, with the aid of mathematics and physics, analyze special features of any one system, but to make the applications one must always bring to bear all the commercial and practical considerations which are also factors of the problems and which cannot be expressed by formulas.

To study intelligently any one problem one must have before him the most salient conditions to be met. Among these characteristic conditions are the following:

(1) The amount and character of business; (2) the local field of development; (3) the density of distribution; (4) the local conditions of cost of real estate for sub-stations; (5) the fire hazards; (6) patents and questions of policy; (7) the cost of capital, and (8) the cost of station supplies.

General considerations of the above character are usually sufficient to determine the main features of the system to be selected; or at least they will shape the problem within well-defined limits, which will point to only a few alternative solutions which can then be treated on their respective merits.

It would be impracticable to attempt to co-ordinate the knowledge we have of the different systems in order to arrive at general conclusions which could then be applied to any individual case. There are, however, general features that any system must possess, and among them the most important are the following:

(*a*) An ideal system should be of the greatest simplicity; (*b*) a distributing system should be as uniform and flexible as it can be made; (*c*) a system must be as economical as possible to install and to operate, at the same time fulfilling the requirements it has to meet; (*d*) a system must be reliable.

We may now see how the different systems commonly used in practice comply with these general requirements. For convenience we may subdivide the systems into *overhead* and *underground.*

Outside of local installations for factories or other plants for special local purposes, we may broadly state that overhead systems are applicable where the territory covered is scattered or the demand for current is light. Underground systems instead are only applicable to territories densely built up with heavy demand for current.

In the case of overhead distribution for lighting in scattered districts, single-phase distribution is usually preferable; two or three-phase generators can be used at the station, and the additional power wires required for any motor installation above 10 or 15 horse-power can easily be strung on the existing pole lines without heavy extra cost. The problem does not present great difficulties, and the engineer is governed by common practice.

In the case of underground distribution in heavily loaded districts, one usually finds an existing system already fully developed, and the extension of that system is usually a foregone conclusion.

There is no definite line of demarcation between these two cases, and it would be difficult to say when it would pay to put an overhead line underground. There is, however, no doubt that when a system has reached a density of about 1000 kilowatt demand per square mile, the extra cost of an underground system is no longer prohibitive, and the standard of the service would be materially enhanced. There are now in America a number of such overhead systems, which have grown to large proportions and which will gradually be put underground in the near future.

It is in these cases particularly that the engineer will be called upon to select a system which will meet the new conditions, and it is precisely in these instances that one is liable to find great differences of opinion among engineers. As this is an important subject of live interest, I shall take a practical case upon which to fix the ideas in the general discussion of the problem of distribution.

Let us assume a concrete case of a medium-sized city, covering a territory of, say, 10 square miles, and having at present the following classes of service:

Series city lighting, 750-kw. max., series direct current.
Multiple incandescent and arc lighting, 1500-kw. max., alt. cur., single-phase.
Power service, 750-kw. max., 500-volt direct current.
Total, 3000-kw. max.

Of the total amount of station output, the business section of the city, covering, say, one-half a square mile, would take about the following percentages:

City lighting	10%—	75 kw.
Incandescent	75%—	1125 kw.
Power	80%—	600 kw.
Total		1800 kw.

The existing customer installation in this district would consist, say, of 150 series arcs, 40,000 equivalent 16-c.p. incandescent lamps, 100 multiple arcs and 1800 horse-power of motors. It is proposed to put this section of business underground. We shall assume that the location of the generating station is fixed by existing conditions, and that the alternating-current generators are wound two-phase, 60 cycles. For a first case we shall assume that the station is 5000 ft. distant from the center of the underground section. Let us then consider the systems that could be applied to the underground territory with the view of selecting a system that shall be *simple, flexible, economical* and *reliable.*

For the sake of simplicity of generation and distribution, we should adopt, if possible, a system having a common source of supply for all services, and a common set of distributing mains similar to the distribution of water and gas. For the sake of flexibility, the network of mains should be a meshed system, making a solid network of cable mains all of one or two standard sizes, so that extensions can be made without replacing any of the cable previously laid. To be economical the system should require low fixed charges for interest and depreciation, have a high efficiency at maximum load and good all-day efficiency. To be reliable any part of the distribution should be free from interruption of current on account of troubles at the generating end or at the transmitting and transforming apparatus. In this country it is customary to insure against any conceivable kind of losses and to consider too lightly the obvious safeguards against the failure of the light and power supply that moves the wheels of trade of the business section of an important commercial center would be an unpardonable mistake of serious commercial detriment to the supply company. On the other hand, an almost absolute guarantee of reliability of service would be invaluable to the successful exploitation of the product. The remarkable success achieved by almost all Edison companies, with their splendid records of continuous uninterrupted service, gives an inkling of the great importance of some of the purely practical considerations not taken account of by theory.

Besides these general qualifications the system should have all those points of superiority that would make the service best adapted to the utilization of the current by present and prospective customers.

It is not probable that all of these requirements could be fully met by any one specific system. We shall have, therefore, to undertake several tentative solutions and then discuss the different results each on its own merits.

The first solution that suggests itself is the continuance of the existing system readjusted for underground conditions. The 500-volt power service and the series city lighting could be readily adjusted for underground operation. The standard American type of subway construction with its great flexibility would not present any difficulties in carrying out this work. For the incandescent lighting we would have to build a system of ducts for drawing in a number of single-phase circuits, feeding one or several transformers at the centers of small districts, each covered by an independent small network of three-wire, low-tension mains (Fig. 1). The transformers would have to be installed either in manholes under the street surface or in kiosks in the street or in the cellars of private customers. Any one of these locations is more or less objectionable. The manhole location requires perfect sewerage conditions, and also requires for reliability of operation that each transformer be fed by a separate feeder, thereby eliminating the primary fuses which are unreliable in a manhole, and also in some cases making possible the use of transformers of low iron and high copper loss, and regulated by individual regulators for each feeder. Transformer-houses or kiosks on business streets are seldom practicable, but would be fairly satisfactory in operation. When insurance regulations allow it and convenient leases for long periods can be arranged, the private building location is preferable. Transformers in this case should be installed in suitable enclosures, these enclosures being accessible by a locked door preferably opening on the street, or in any event always accessible at any hour of the day or night. The dependence upon a number of private owners is, however, somewhat of a drawback in most instances where this system is in use in this country.

Let us assume to have settled upon a definite location as found best suitable for the conditions. In the case of manhole transformers for commercial and technical reasons, it will be advantageous not to make the transformers and districts too small and for safety not too large. We can then decide upon say 12 100-k.w. transformers, supplying 12 independent districts. For emergency conditions we shall provide suitable switches for tying together neighboring districts, thereby making it feasible for the trouble man to give temporary relief to a district which, through the failure of its primary feeder or transformer, has been put out of service.

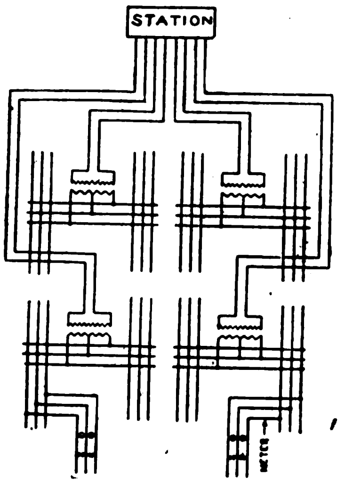

FIG. 1.

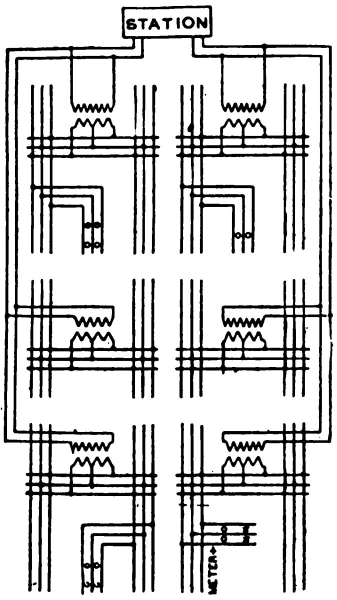

FIG. 2.

In the case of transformers in kiosks or private buildings, we may safely use secondary fuses with the transformers and connect several of them so as to feed into a large meshed network of mains. We may, for instance, divide the whole underground section into two districts designed to subdivide the load approximately equally between the two phases of the generators, and in each district have six primary feeders, with 100-kw. transformers, as before, the only difference being that the secondaries of each six transformers would be connected in a meshed network of mains, each transformer being protected by secondary fuses or by circuit breakers in case of large transformers.

By using different criteria in design and adopting good regulating transformers, we may arrange the primary feeders for the two districts last mentioned in a different manner. We may use two single large feeders, connecting all six transformers in multiple for each district (Fig. 2). This arrangement requires primary fuses for each transformer and independent secondaries for each transformer district. To mesh into a network also the secondary mains of the six districts, thereby forming a meshed primary and meshed secondary, distribution would be unsafe owing to the difficulty of properly subdividing the loads among the different transformers; this is, however, done in some cases and with proper protective devices and careful study of the layout the system might be made operative. It is understood that with this system the regulation of all six transformers being done at the station upon a single feeder, this must be designed for a small maximum drop not to exceed, say, 2 per cent, otherwise poor regulation will result. The all-day efficiency of the system is, however, lower than in the case of the individual feeders for each transformer; it is, therefore, better adapted to plants where energy is cheap, as in water-power plants.

The solution of our problem along the above lines would not give us the desired unification of the generating station; the subdivision of the underground system into small districts would not give us the advantages of a meshed network, thereby reducing to some extent its flexibility and largely the reliability of service of any one district. In fact this continuity is dependent exclusively upon the year in and year out absolute freedom from failures and breakdowns of any part of the long cable feeder and transformer supplying the network of mains in the district.

As to economy, one can see without making calculations that the three independent systems of generation and distribution of current for the three separate classes of service cannot lead to maximum economy of investment and cost of operation and maintenance.

The unification of generating apparatus can readily be decided upon from the consideration of respective percentages of power required for different services. As 50 per cent of the total output is for alternating 60-cycle lighting, 25 per cent for direct-current series arc lighting and 25 per cent for 500-volt power, and as the alternating current 60-cycle service for the overhead distribution is a necessity, the selection of alternating-current 60-cycle generation is a foregone conclusion. The series direct-current service could, in the majority of cases, be economically transformed into a series alternating-current system with constant current transformers; or, if preferable, the direct-current arc machines could be operated by alternating-current motors, the selection depending upon consideration of local requirements. Whatever developments in the art of arc lighting may follow the investigations and experiments that are now being made, they will not be in the way of the direct or indirect use of alternating current. The 500-volt power generation could be obtained from motor-generator sets, the motors being operated from the 60-cycle alternating-current supply. It is, however, doubtful if the existing 500-volt generating units are reasonably efficient, that it would pay to discard them and add the investment of new motor-generator sets. In many cases we may, therefore, have to abandon the idea of unification of generating apparatus and possibly only add some synchronous motor-generator sets that would tie together the two systems and serve as reserve, and also for shutting down the system at light loads.

We would, therefore, have a composite station with 75 per cent in alternating-current generating capacity and 25 per cent 500-volt, direct-current generating capacity. Any further step toward unification of the system will depend entirely upon what can be accomplished in the unification of the distributing system in the underground district representing the bulk of the commercial light-and-power service. We may neglect the question of the city series arc in this district, as most probably the series alternating-current system would do for the case or multiple arcs fed from the lighting mains could easily be adopted, if found convenient. The serious question to face is the supply of current to motors. If single-phase, alternating-current motors could be made to operate under the same conditions that direct-current motors are operated, there is no question that even at the large sacrifice of replacing with new alternating-current motors the 1800 horse-power of customers' motors, it would pay in the end to do it, as we would save the duplication of separate mains for light and for power and we would be in the position of securing the advantages of unification of station apparatus and more economical operation. At present single-phase alternating-current motors cannot meet these requirements, and as the several attempts to develop a commercially satisfactory single-phase motor have been only partially successful, we may exclude it from consideration. The promises held forth in the field of single-phase railway motors may eventually bring the long-wanted solution, but at present, while there are undoubtedly many cases where single-phase motors could and should be used, we still shall have to operate the 500-volt power circuit for a number of cases where the present single-phase motors are not applicable. Therefore, we are brought to the conclusion in favor of a composite alternating-current and 500-volt, direct-current generating station and duplicate system of distributing feeders and mains for light and for power. This conclusion seems hardly logical, but there are open only two other alternatives, which are hereafter discussed.

The first alternative is the adoption of polyphase-current distribution for the underground districts as used for the overhead district. The second is the distribution of direct current through an underground

Edison three-wire system. Before comparing these two systems, we must make a statement of fact that as far as the electric service requirements in the business section of a city are concerned, the direct-current systems have no drawbacks to contend with in the unlimited variety of their applications, while the alternating-current systems, without any advantages in efficiency, are, in many cases, handicapped by limitations in their adaptabilities to meet important uses, as, for instance, in the case of variable speed motors for elevators and hoists and the direct charging of storage batteries. The greater adaptability of direct-current motors in city work is, in the case of low-speed motors, usually accompanied by lower first cost and higher efficiency of operation. Another consideration is the presence in a business section of quite a number of private plants, all operating direct-current generators and translating devices. Central station break-down connections for these prospective customers become impossible with alternating-current systems of distribution, and their limitations in adaptability to specific services and the difficulties encountered in readapting the existing installations of motors and arc lamps make the eventual full central station service to these customers very difficult to secure, without making local installations of direct-current converting apparatus to be operated continuously. A few large installations of this kind would weigh a good deal in the final results. Returning now to the study of the application of polyphase and direct-current systems, we shall take up first the polyphase system.

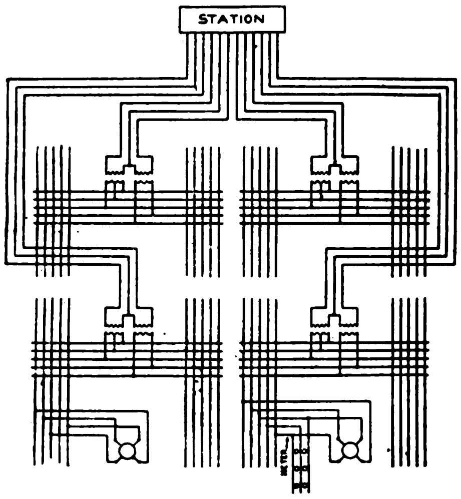

FIG. 3.

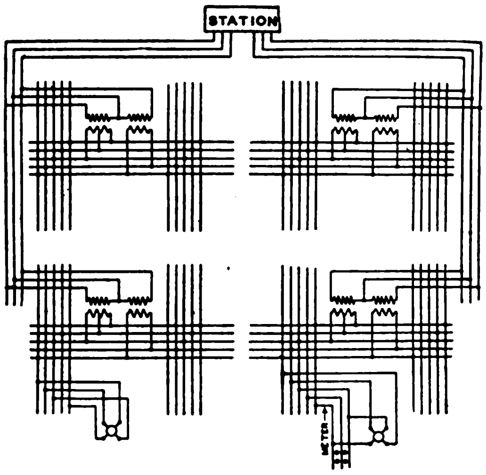

FIG. 4.

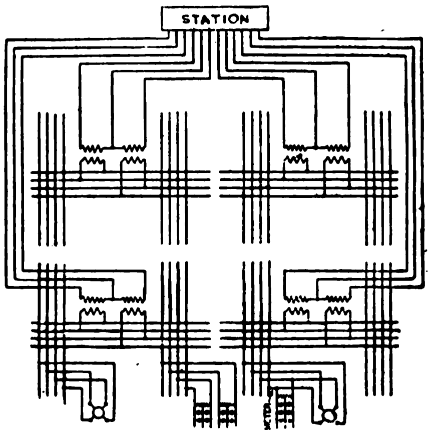

FIG. 5.

Having at the generating station two-phase generators, we shall lay out an underground two-phase system. By rewinding the generators it may be feasible to use three-phase distribution if we shall find it preferable. The two-phase distribution could be accomplished according to several plans. One plan would be to adopt the single-phase distribution for light by districts, as in the previous case, and parallel the system with primary feeders, transformers and a two-wire network of 220-volt mains of opposite phase for power (Fig. 3). The primary feeders could be two duplex cables or one three-conductor cable, using the third wire for the power circuit, regulators being mounted only on the lighting circuit. This system would not be less complicated than the previous system with 500-volt direct-current mains, its only advantage being the unification of generating apparatus at the station.

A two-phase three-wire meshed primary and a three-wire meshed network of 110-volt mains could supply light and power to the whole district (Fig. 4). It is an unbalanced system even at equal distribution of loads among phases; it requires a large amount of copper for mains, on account of the low voltage; the metering of current at customers' premises requires polyphase meters or two single-phase meters for each class of service; the neutral of the three-wire wiring in buildings must be of larger cross-section than the outside wires, which is not always the case in existing installations. On account of all these drawbacks, this system may be discarded for our case. By using a five-wire meshed network of 220-volt mains, the total amount of copper for mains could be reduced, but it would add complications of wiring without corresponding advantages.

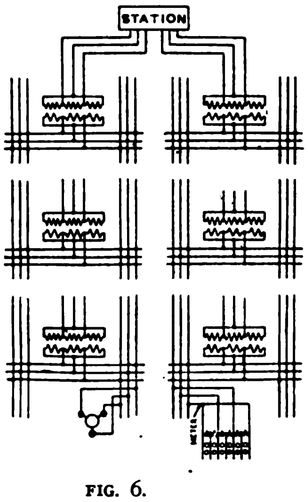

FIG. 6.

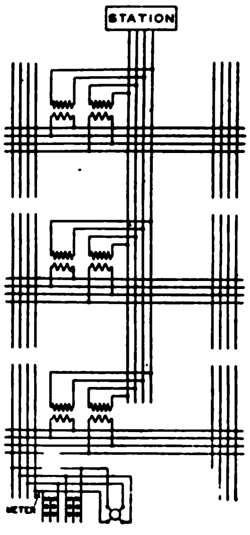

FIG. 7.

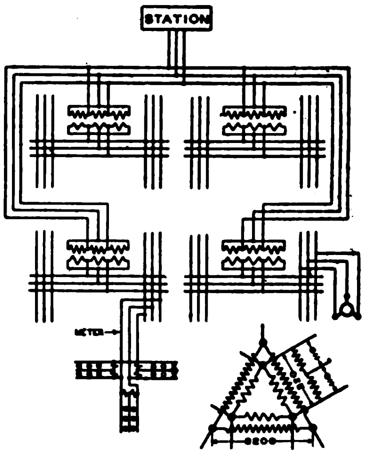

FIG. 8.

A duplicate three-wire single-phase system along the lines first described would have the advantage of good regulation with reasonable requirement of copper, but the six cable wires would be cumbersome and costly. By omitting the neutral wire and delivering 220-volt current for each phase the last system could be reduced to four wires, which would be an advantage if 220-volt incandescent lamps were as efficient and 220-volt arc lamps as satisfactory as 110-volt lamps. In 1901* the writer demonstrated that for conditions similar to the one under consideration, it would not be economical to use 220-volt lamps. The tendency upward due to the advantages of high voltages in the case of the Nernst lamps is now offset by the tendency to lower voltages in the osmium lamps. We have, therefore, to discard the system as unsuitable for our conditions. We could, however, install at each customer's premises a balancing 2 x 110-volt transformer, which would permit us to use the two-wire 220-volt mains and the more efficient 110-volt lamps (Fig. 5). In most of the cases this arrangement would work well, but in a dense district such as we have under consideration, the first cost of these balancing transformers, together with their losses, would undoubtedly make the system as expensive as the neutral main wires which they replace. This system is, however, the best that can be made out from a two-phase distribution, and we shall, therefore, give to it further consideration in our final selection.

If we adopt three-phase generators we

---

*Transactions of the A. I. E. E., vol. xviii.

can select between a three-wire or a four-wire system for the primary feeders and several combinations of secondary mains. The straight three-wire primary would, perhaps, be preferable; we would then use three-phase or two-phase T-connected transformers and make the combinations desired on the secondaries. We can then distribute through a three-wire network of 110-volt mains, but its cost would be high. We can distribute through a six-wire network of 2 x 110-volt mains, but the six-cable mains would be cumbersome and expensive. We can distribute through a three-wire network of 220-volt mains, but it would not be economical on account of the low efficiency of 220-volt lamps. By the use of the balancing transformers (Fig. 6), we would obtain the best workable three-phase three-wire system, which we shall consider later.

By dividing the underground territory into three equal districts and operating three-phase generators, one can lay out some system by which light is delivered single-phase by a three-wire network of mains for each district, and power from an additional two-wire cable main. This system, which works very well for overhead conditions, would be expensive and undesirable for underground conditions.

From this review of the alternating-current systems with distributed transformers, we have found that the following systems are more or less desirable, but all of them possible for our conditions:

Case A.—Single-phase distribution of light, 500 volts for power separate (Fig. 1).

(1) Twelve independent two-wire primary feeders, equally divided between the two phases, each one feeding a separate secondary district, consisting of a single-phase transformer supplying a three-wire, 2 x 110-volt network of mains.

(2) Same as (1), but with each group of the same phase of secondary district mains connected in two solid mesh networks.

(3) Same as (1), but with only two single-phase, two-wire primary circuits, one for each phase, mesh primaries (Fig. 2).

Case B.—Two-phase distribution for light and power.

(4) Twelve independent three-wire primary feeders, each one feeding a separate secondary district consisting of a set of two-phase transformers, supplying a three-wire, 2 x 110-volt network of mains, and a two-wire, 220-volt network, the latter being used for motors only (Fig. 3).

(5) Same as (4), but with two halves of the district mains connected in two solid secondary mesh networks.

(6) Same as (4), but with only two sets of two-phase primary circuits, meshed primaries (Fig. 4).

(7) Twelve, or less, two-phase primary circuits and sets of two-phase transformers with twelve, or less, districts, covered by duplicate two-wire, 220-volt; single-phase network of mains, with balancing transformers at customers' premises for lighting, the lighting of each customer being from one of the single-phase circuits, the balancing of phases being accomplished by distributing evenly the customers' connections between the two phases (Fig. 5).

(8) Same as (7), but with the mains of all districts connected in a solid meshed secondary network.

(9) Same as (7), but with only one set of two-phase primary circuits, meshed primaries (Fig. 7).

Case C.—Three-phase distribution for light and power.

(10) Twelve, or less, three-wire, three-phase primary feeders, each one feeding a separate secondary district consisting of a three-phase transformer supplying a three-wire, 220-volt, three-phase network of mains with balancing transformers at customers' premises for lighting, the installations of any importance being wired for three independent three-wire circuits, one for each phase (Fig. 6).

(11) Same as (10), but with the mains of all districts connected in a solid meshed secondary network.

(12) Same as (10), but with only one set of three-phase circuits, meshed primaries (Fig. 8).

As an alternative to any of the above systems with distributed transformers, we may select equivalent secondary networks of mains, fed by low-tension feeders from a single sub-station, at which are located all the step-down transformers. As we have already noted the practical drawbacks of distributed transformers in a heavily-loaded district, it is important to give the case of a sub-station thorough consideration. The objections to the distribution of large amounts of alternating current, through lead-covered cables, are in practice less serious than one would expect. Care must be taken in the sub-station and subways to eliminate looping of phases with iron pipes or other magnetic materials, but the difficulties would not be greater than in all other wiring for alternating-current distribution.

For our underground district, we could apply four layouts corresponding to (2), (5), (8) and (11), which we shall designate respectively by the numbers 13, 14, 15 and 16.

(13) With a single-phase for lighting and 500-volt, direct current for power, the alternating-current distribution from sub-station could be accomplished by dividing the system into two equal and independent sections, for balancing the phases of the two-phase generators, and feed the two sections, each covered by a meshed network of mains, by means of low-tension feeders in the same manner that Edison three-wire systems are operated. For feeders and mains the Edison tubes would fill the requirements exceedingly well, though for practical reasons cables would be preferable. In cases of cables the feeders should be of multi-conductor type, making them the equivalent of an Edison three-wire tube; the mains should preferably be single-conductor cables. The regulation of each feeder could probably be efficiently obtained by having the secondaries of the step-down transformers built with a neutral tap at the middle and a 10 per cent or 15 per cent tap on each end, each tap being connected to corresponding station busses, the middle bus being for the neutral of the feeders and the two sets of outside busses being intended for connecting of an auto-transformer regulator mounted on each outside leg of the low-tension feeder. The two regulators would give perfect regulation for drop in feeders as well as for unbalancing of the two sides of the three-wire system. The single-phase, two-wire, 220-volt distribution with balancing transformers at customers' premises would save the neutral wire of feeders and mains; a balancing transformer at the end of each feeder would save the neutral feeder wire. In the case of a two-wire, 220-volt distribution with balancing transformers, it may be desirable to distribute the two-phase current, single-phase, from a single set of busses into a single meshed network of mains. This could be done by using the transformers of special design and of somewhat larger capacity, connected in two-phase relation on the primaries and the two secondaries in series delivering single-phase current (Fig. 10). The secondary winding must be specially designed for avoiding magnetic unbalancing on account of the regulating taps on one end of each transformer.

(14) With two parallel sets of low-tension feeders and mains, one single-phase, three-wire for lighting and power, and one alternating-current, two-wire, 220-volt for power only, the system would require similar layouts, as just described, for the single-phase system (13), with the addition of two-wire circuit feeders and mains for which, however, no regulation would be required at the sub-station, thereby making the sub-station connections rather simple and, perhaps, also, poor regulation in the line permissible. With this system it would be necessary to operate the underground districts divided into two equal sections operated from two busses (Fig. 11). With balancing transformers at the end of lighting feeders or at customers' premises, the neutral wire in feeders, or feeders and mains, could be saved, thereby making the distributing system four-wire instead of five-wire.

(15) By connecting lights on both circuits of the four-wire system last mentioned, we would have independent wires, two-phase distribution with two wires, 220 volts on each phase and balancing transformers at the customers' services. The balancing of phases would be accomplished from house to house. The secondaries would form a solid meshed network of four-wire mains. Both mains in each street require regulation at the sub-station and same regulation in lines (Fig. 12).

(16) Three-phase, low-tension distribution can be done by three-wire, 220-volt feeders and mains and balancing transformers at customers' premises, balancing of phases being accomplished by subdividing important lighting customers' wiring in three equal and independent parts, one for each phase (Fig. 13). Independent regulation of each phase is practically impossible with this system; each phase being dependent upon a fixed relation to the other two, making it necessary to act at the same

time and in different degrees upon all the phases. This regulation can be accomplished better on the high-tension side of the three-phase transformer by individual regulators on each of the three legs. In practice with generators of good regulation and a large network of three-phase, low-tension feeders and mains mesh connected in conjunction with the compensating effect of all three-phase motors, it is probable that independent regulation of phases could be done away with. It would be necessary for the regulation of each feeder to provide a step-down transformer with its primary regulator for each feeder, which, however, is not a drawback, as in our case transformers of 200 or 300 kw. capacity could be used. This would give the greatest independence, but it requires the continuous operation of all step-down transformers, unless some combination of switches is arranged on the feeders at the sub-station, by means of which a combination of two or three feeders can be operated from a single transformer and the underload transformer cut out of service. Accordingly, for the last conditions, which are preferable for good service, the transformers should be designed for highest full load efficiency, while in the case of continuous operation they should be designed for the lowest iron losses.

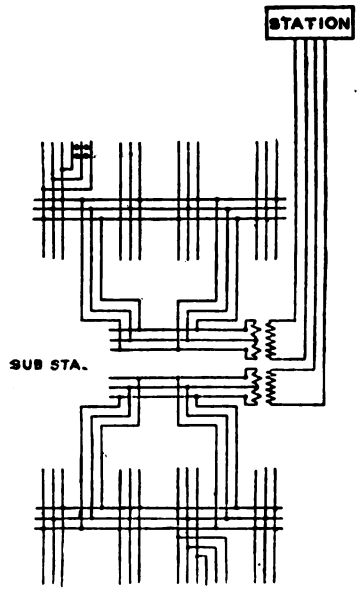

FIG. 9.

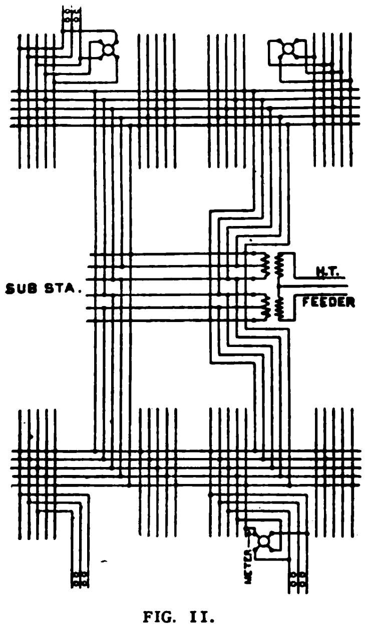

FIG. 11.

While it is theoretically possible to make a sub-station layout which would not require station attendance, this would not be suitable in practice.

We have thus described the possible layouts for alternating-current distribution. By the use of a sub-station with motor-generator sets, we should feel justified in excluding rotary converters; on account of the 60-cycle frequency, we may distribute direct current to an Edison three-wire system covering the underground district with a solid meshed network of mains (Fig. 14).

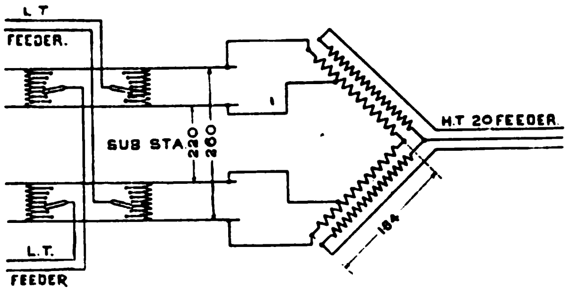

FIG. 10.

(17) By the use of 250-volt lamps and three-wire, 2 x 250-volt mains, existing motors could be operated from the same lighting mains, but we have already pointed out the undesirability of this plan for our conditions—first on account of the low efficiency and higher cost of renewal of high voltage lamps and inferiority of arc lamps, and also on account of making necessary the rewiring of all old customers' buildings.

(18) With two 110-volt mains, the existing 500-volt motors would have to be rewound, but no important changes in customers' wiring would be required. If direct-current distribution were selected, this system, while more expensive, would perhaps be preferable to the 500-volt, three-wire system, on account of the superiority of 110-volt incandescent and arc lamps.

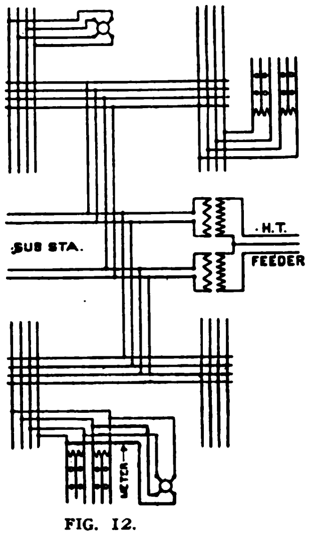

FIG. 12.

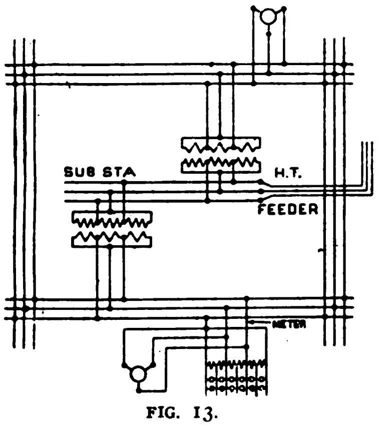

FIG. 13.

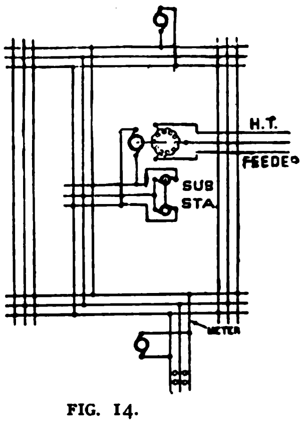

FIG. 14.

For the 18 possible solutions of our problem above outlined we have pointed out a few of the advantages and disadvantages of each system; now by applying some of the general practical considerations we might be able to select among the 18 cases a few that would best suit our conditions. But before proceeding to this elimination we may first figure out the relative economical values for all cases so that our selection may be guided by this requirement as well as by all other requisites of the conditions we have assumed.

In Table I we have given on general lines the main items of cost which are variable for different systems, leaving out of consideration small details and items which would be practically identical for all systems.

The title with the foot notes and comments of Table I explain the assumptions and points to be taken into account in making the comparisons.

The high-tension feeders have been figured for slightly different drops to fit the practical conditions, the lowest being 2.4 per cent and the highest 3 per cent for the length of 5000 ft. assumed in the case. (For larger distances of generating station from distributing centers the line drop and cost of high-tension feeders would be correspondingly increased.) The average maximum line drop of low-tension feeders has been assumed as 11.6 per cent for the 500-volt power circuits, and from 5.2 per cent to 9.4 per cent for low-tension feeders for lighting or for light and power combined. The line drop in mains was in all cases very close to 1 per cent.

The efficiency of transformers at full load has been assumed at 97.5 per cent in all cases, and the efficiency of motor-generator sets at 85 per cent. Column G, giving the maximum load efficiencies, has been worked out from the above figures. The average load efficiencies of column H were estimated for the most favorable conditions.

Table I shows cost of cables and transforming apparatus for 18 possible solutions of the problem of putting underground the present overhead distribution in the business section of a medium size city now supplying 1200 kw, maximum alternating-current lighting 600 kw. maximum, 500-volt direct-current power, to an installation

42,500 equivalent 16-c.p. incandescent and arc lamps, and 1800 horse-power of direct-current motors. The section covers one-half square mile with 69,000 ft. of streets with mains, and its center is assumed to be 5000 ft. from the generating station, equipped with 2200-volt two-phase 60-cycle alternating and 500-volt direct-current generators.

TABLE I.

System.	High-tension feeders.	Low-tension feeders.	Low-tension mains.	Balancing transformers.	Transformers or motor generators.	Total.	Total efficiency of system. At maximum load.	Total efficiency of system. Average all day.
	A	*B*	*C*	*D*	*E*	*F*	*G*	*H*
1 and 2	$34,080	$25,220	$81,110	.....	$8,400	$148,810	91%	91%
3	17,280	25,220	81,110	.....	8,400	132,010	91%	88%
4 and 5	35,500	5,220	95,910	.....	13,000	149,630	93%	92%
6	28,184	5,220	95,910	.....	13,000	142,314	93%	91%

15	18,750	46,750	71,760	7,000	9,000	153,260	85%	88%
16	18,750	28,180	66,240	10,000	9,000	148,730	86%	89%
17	18,750	18,181	44,505	.....	50,000	131,436	80%	82%
18	18,750	38,900	66,240	.....	50,000	173,922	74%	77%

No. 1, No. 2, No. 3. Mixed systems, single-phase, alternating-current lighting, and small motors with high-tension feeders to 12 transformers feeding low-tension three-wire mains, with 500-volt direct-current power mains.

No. 4, No. 5, No. 6. Single-phase lighting, as before, but alternating current, two-phase power in place of the 500-volt direct-current distribution.

No. 7, No. 8, No. 9. High-tension feeders and two-phase lighting and power from four-wire low-tension mains.

No. 10, No. 11, No. 12. High-tension feeders and three-phase lighting and power from three-wire low-tension mains.

No. 13, No. 14, No. 15 and No. 16. Respectively similar to No. 2, No. 5, No. 8 and No. 11, but with transformers in sub-station and low-tension feeders to mains.

No. 17. 500-volt, three-wire distribution for light and power from sub-station with motor-generator sets.

No. 18. 220-volt, three-wire distribution from sub-station with motor-generator sets.

Before comparing the values in column F, we must make a number of corrections and allowances which could not be readily incorporated in the table. Among the most important are the following:

(*a*) No figures were given for cost of ducts, the difference between the several systems being probably small except in cases where double distributing ducts are required. In the eight cases No. 1 to No. 6 and No. 13 and No. 14, all having five-wire distributing mains, it will be necessary to have double distributers which, figured on an increment cost basis, would amount to, say, $23,000.

(*b*) For cases No. 4 to No. 12 and No. 14, No. 15 and No. 16, distributing polyphase amount for power, we must add the cost of replacing the existing 1800 horse-power of direct-current motors with alternating-current motors. For our estimate we may assume this cost at $50,000.

(*c*) For case No. 17 we would have to rewire practically all the existing customers' incandescent and arc lamp installations at an estimated cost of, say, $50,000.

(*d*) For case No. 18 we would have to rewind or replace all 500-volt motors with 220-volt motors at a cost of, say, $25,000.

In Table II, column F_1, are given the revised values with the corrections (a), (b), (c), (d), added to column F of Table I. For comparing the cost of different systems we must use column F_1 of Table II in the case of existing installations; for the case of new business we must use either column *F* or column F_1, according to whether the new business is for a customer not already supplied with current or otherwise. The importance of existing private plants operating in the territory, the annual rate of increase and the ultimate growth of business will decide which course to take in the comparison. The conditions for the future are, however, in most cases difficult to judge, as they are dependent upon new and unforeseen developments. Therefore, unless a proposition can show more or less immediate advantages on its own merits under existing conditions, we shall assume that it would be entirely speculative and unsafe to follow. In our present case of a medium-sized city, whose business grows at a rather moderate rate from year to year, we feel justified in assuming that the system selected must show substantial immediate advantages under present existing conditions rather than distant future savings. Therefore, while we will give due consideration to the final results, we shall, however, be guided more in our selection by the values given in column F_1 of Table II rather than by the increment values of column *F* of Table I.

To reduce the relative values of efficiencies to a money basis we have assumed a load factor of 25 per cent and figured out the total losses in Table II on the basis of an increment cost of production of one cent per kw.-hour. (With cost of coal very high or very low or with water power plants this figure may be either too low or too high.) In the case of systems requiring a sub-station we have added $3000 for its cost of operation.

TABLE II.

System.	Total cost of system.	Yearly cost of inefficiency losses.	Yearly cost of sub-station operation.	Total yearly cost (M + N).
	F_1	*M*	*N*	*P*
1 and 2	$171,810	$2,500	....	$2,500
3	155,010	3,400	....	3,400
4 and 5	222,630	2,200	....	2,200
6	215,314	2,500	....	2,500
7 and 8	184,220	2,200	....	2,200
9	173,555	2,750	....	2,750
10 and 11	181,960	1,900	....	1,900
12	171,295	2,750	....	2,750
13	178,876	3,100	$3,000	6,100
14	242,292	3,100	3,000	6,100
15	203,260	3,400	3,000	6,400
16	198,730	3,100	3,000	6,100
17	181,436	5,500	3,000	8,500
18	198,922	7,500	3,000	10,500

With the aid of Table II and all that has been previously said, we may now proceed to analyze the several solutions with the view of making the final selection.

Systems No. 4, No. 5, No. 6 and No. 14, the most expensive as to first cost, have no special points of superiority to commend them to us, and we shall, therefore, exclude them from further consideration.

System No. 17, while reasonably economical as to first cost, is inefficient, its losses being only exceeded in one other case; and, furthermore, it requires the operation of inefficient and more expensive high voltage incandescent lamps and unsatisfactory arc lamps. This system is, therefore, unsuitable for our conditions.

Systems No. 3, No. 9 and No. 12 require low investment and are all reasonably economical. The essential feature of all three is the presence of only *one* or *two* high-tension feeders supplying all the current for the underground section, this section being divided in numerous independent districts of distributing mains. There is no question that the resultant economy is accomplished at a heavy sacrifice of the reliability of service, and it is questionable if a similar plan would be given preference when almost as good results could be obtained with the corresponding systems No. 2, No. 8 and No. 11, having several independent high-tension feeders supplying current to one or two solid meshed network of mains. We shall, therefore, have to select from systems No. 2, No. 8 and No. 11. (The systems No. 1, No. 7 and No. 10 are practically identical with No. 2, No. 8 and No. 11, but the latter are preferable if they can be adopted, having a solid meshed network of mains instead of subdivided districts.) Between No. 8 and No. 11 there is, perhaps, little choice. The costs are practically the same; No. 8 transmits two-phase high-tension current, three-wire, which is undesirable, but the line drop being less than 3 per cent this drawback is not serious. It has the advantage over the three-phase system No. 11, that each phase can be regulated a good deal more independently than the three-phase. In our case, having assumed to have two-phase generators at the station, we may give the preference to No. 8 over No. 11. Between No. 8 and No. 2 the differences are of greater moment. With slight differences in first cost and economy system No. 2 has the advantage of supplying direct-current power to motors, which requisite we assumed to be a desideratum in our case.

Between systems No. 15 (two-phase) and No. 16 (three-phase), the differences in favor of No. 16 are too trifling to counterbalance the greater advantage of absolute independent regulation of phases of No. 15. We shall, therefore, discard No. 16.

By successive eliminations we have brought the problem to the selection between four systems, No. 2, No. 13, No. 15 and No. 18. The last three require a sub-station, while system No. 2 does not. If local conditions warrant the direct distribution from the generating station to transformers in manholes or customers' premises, system No. 2 has such marked advantages over the other three systems that its selection would be a matter of course. In case the sub-station is found necessary we must select between No. 13, No. 15 and No. 18. System No. 13 does not give us the desired unification of generating apparatus, but its advantages in first cost and efficiency together with the possession of the requisite of supplying direct current to motor will, without doubt, outweigh the drawbacks of a composite station, especially if we should equip the station, or, if preferable, the sub-station, with a motor-generator set as a tie and a reserve between the two systems. We have arrived at the above conclusions on the assumption that the generating station was within 5000 ft. of the center of the underground district. It is now important to note what difference it would make if the station were not so favorably located. Referring to Table I, we see that only columns *A* and *G* and *H* would be affected. If we assume to use high-tension cables of the same cross-section as before, the cost will increase in direct proportion to the length and the line drop will also increase in the same ratio. The values of *G* and *H* will change relatively in approximately equal proportion, and for the present investigation we shall not need to revise the deductions as far as deduced from the efficiency values of columns *G* and *H*.

The only limitations will be the difficulties of transmitting 500-volt current too great distances and the poor regulation of the alternating-current system with too large line drops. In general, it is improbable that the direct-current generators supplying the 500-volt power service be installed at a station very distant from the center of distribution; it is, therefore, reasonable to suppose that where the alternating current main station is at greater distance than two or two and one-half miles, there is also a direct-current 500-volt subsidiary station near the distributing center. This is by no means a hypothetical case, as we find similar conditions in many places. Let us then assume that the previous conditions were changed to the existence of two generating stations, one direct current at 500 ft. and one alternating current at 15,000 ft. from the center of distribution, all other conditions remaining the same. The larger stations can be assumed to be better situated for operation. We should like, if possible, to discontinue the operation of the smaller stations; the subject will, therefore, require careful study. Let us assume that it has been proved advantageous to do away with the direct-current station by substituting 500-volt direct-current motor generator sets at a convenient sub-station, or transform the 500-volt service if a better solution is available. The polyphase alternating-current system considered before would enable us to do away with the sub-station entirely, but can we still transmit economically the alternating-current to a distance of 15,000 ft., as was the case where the distance was only 5000 ft.? By referring to Table I, column *A*, we find that if we multiply by 3 the values therein given, we obtain the approximate variation in the cost of feeders. This cost for system No. 8 or No. 11, which we have found to be the most desirable for polyphase distribution, would amount to $106,500 for both cases. The cost for high-tension feeders in the corresponding cases, with sub-stations (systems No. 15 and No. 16), would be $56,250, a difference of $50,250 in favor of the sub-station; this without considering the undesirability of very long high-tension feeders for separate district transformers.

We see, then, that after a certain distance, exceeding two or two and one-half miles, the problem of distribution becomes a problem of transmission. In such cases it is necessary to have a step-down sub-station at the distributing center.

For our new problem we shall then have to consider only the systems No. 13 to No. 18, suitably revised.

We may neglect the high-tension feeders to the sub-station, as they will be the same in all cases; from the sub-station we could distribute high-tension current to transformers distributed all over the system, as in cases No. 1 to No. 12, but having to operate a sub-station it would be preferable to attain the advantages of the direct distribution by locating the same at a convenient place, near the center of distribution of the underground district.

With the exception of system No. 13, the other five systems, No. 14, No. 15, No. 16, No. 17 and No. 18, would have the same relative values as in Table II. System No. 13, however, would have to be revised in so far that the 500-volt power cables would be somewhat cheaper on account of the sub-station being nearer the center of distribution than in the previous case. This saving is estimated at $12,000. On the other hand, the cost of motor-generator sets would more than offset this saving; furthermore, it would be necessary to provide some reserve capacity. Making such allowances the net cost of system No. 13 would be increased at least $10,000. Other things being equal, the efficiency at maximum load and the all day efficiency will both be reduced about 3 per cent in each case. Therefore, the relative values of Table II for systems No. 13 to No. 18 will apply to the revised conditions with the exception of system No. 13, for which the total cost (F_1) will be $188,876. The yearly cost of inefficiency losses, column *M*, will amount to $4000, and the total, column *P*, will be $7000, instead of the values given in Table II.

Discarding systems No. 14 and No. 17 for the same reasons given before, we have now left to select between them four systems, No. 13, No. 15, No. 16 and No. 18. Their respective values, columns F_1 and *P*, as revised, are as follows:

System.	F_1	*P*
No. 13	$188,876	$7,000
No. 15	203,260	6,400
No. 16	198,730	6,100
No. 18	198,922	10,500

The maximum difference in investment costs between these systems is less than $15,000, while the difference in yearly costs of operation is $3400. Estimating the total business effected to represent 2,500,000 kw.-hours sold to customers, the maximum difference per kw.-hour would be .14 cent. This would be the amount saved by the polyphase system No. 16, over the straight direct-current system, No. 18. On the other hand, if we compare No. 13 and No. 16, the difference in cost of operation is reduced to $900, or to less than 4/100 of a cent per kw.-hour sold. In view of the preference for the direct-current motor assumed as a premise of our problem, the selection of system No. 13 becomes very evident. A great number of engineers would perhaps go as far as to select the straight direct-current system No. 18, but considering that with system No. 13 one may gradually develop considerable single-phase motor load in small units and save a good deal of the 500-volt cable investment in streets without motors; and as the present prospects of developments of variable speed alternating-current motors are more promising in the single-phase than in the polyphase type, and as the single-phase distribution is superior for operation, for regulation and for cost and maintenance of meters at customers' premises, we would give it preference over the other systems. These figures and these conclusions may be somewhat surprising for two reasons: First, because it is not generally appreciated how an apparently inefficient system like the direct-current system can so closely compete with polyphase alternating-current systems on the very point of total cost of distribution and apart from other considerations of commercial or practical character as to the superiority of either system; second, because these close results appear to apply even to the case of relatively small centers where the density of current supply per foot of street is greatly below the average density found in large cities.

In the case of large cities it is, however, only pertinent to note that high-voltage transmission and the use of 25-cycle rotary converters improve considerably the efficiency over the efficiencies assumed in our case of 2200-volt, 60-cycle motor-generator sets, thereby bringing the total efficiency of the direct-current system much closer to the alternating-current systems. To bear out this point we may compare the relative amount of cable investment per kilowatt, maximum load at generating station for two large companies, one distributing direct current and the other alternating current with distributed transformers. The values, which are based on the pounds of copper in cables and not the cost of cables, are approximately as follows:

	Lbs. copper per kw. max. Alternating.	Direct.
High-tension feeders	114.9	20.5
Low-tension feeders	....	83.2
Low-tension mains	68.7	67.0
Total	183.6	170.7

If one considers that high-tension cables cost considerably more per pound of copper conductor than low-tension cables, it is evident that the comparison would be still more favorable to the direct-current system. This difference is also felt in the maintenance of the system, as even if the life of low-tension and high-tension cables is assumed equal, their scrap value at the time of renewal will be from 25 per cent to 100 per cent lower for the high-tension cables than for the low-tension cables. This will amount to correspondingly higher cost of maintenance of the alternating-current distributing system than for the low-tension system. The higher intrinsic value of the property will also indirectly affect favorably the financial standing of the company, so that it is reasonable to expect that some benefit is derived therefrom in the event of the selling of the property, or in case of making money loans, or even in the market value of the securities issued by the company.

In closing this review of a rather complex and many-sided problem, we cannot omit to at least note the important part played by the storage battery in making the combination of alternating-current and direct-current systems complete and absolutely reliable.

[The foregoing is a paper read at the International Electrical Congress at St. Louis.]

◆◆◆

ILLINOIS STATE ELECTRICAL ASSOCIATION CONVENTION.

The annual convention of the Illinois State Electrical Association was held this year on October 5 and 6, at Decatur, Ill. After the reports of the secretary and treasurer were read and the routine business disposed of, a discussion of insurance rates and fire insurance was taken up. The afternoon of the first day of the session was given over to a consideration of a number of questions filed with the secretary for the "Question Box." Answering the question: "What economy is there in the use of compound as compared with single-expansion engines at pressures of 100 pounds and less?" R. S. Wallace thought at full load about 10 per cent if the engine used is condensing, but not much without condensers; on fluctuating loads the economy was questionable. The precautions necessary in paralleling alternators formed the subject of the next question. F. L. Lucas drew attention to the necessity of being able to adjust engine governors while the engines were in operation, so as to make them take their proper share of the load when driving alternating-current generators in parallel. Regarding methods of voltage regulation which have proven successful when single-phase lighting circuits are distributed across the phases of three-phase machines, when these machines also served highly inductive loads in motors and arc lamps, it was said that an induction regulator accomplished this satisfactorily. In answer to a question of how often switchboard instruments should be tested to insure reasonable accuracy, Mr. Wallace stated that he tested indicating instruments every six months, whereas the integrating wattmeters measuring the total station output were calibrated every two months. G. L. Lukes thought switchboard voltmeters should be compared with a standard of known accuracy every month or two, since the maintenance of correct potential is essential in operation. With ammeters accuracy was usually not so important. "What method of treating wooden poles gives the best result in preserving the tops and butts from decay?" was the next question. Mr. G. C. Kinsman pointed to the fact that the Western Union Telegraph Company with its years of experience did not treat or paint its poles in any way. The average life of Western Union poles, he said, was sixteen years.

The session then adjourned to witness the exhibits of specialties provided by the electrical supply men. The next morning the "Question Box" was again taken up. The connecting of small plants with adjacent towns six or eight miles distant and having a population of from 800 to 1000 was deemed advisable, as in many cases cited this was shown to be both successful and profitable. The joint occupancy of poles by electric light and telephone companies was then discussed. The concensus of opinion seems to have been that this was preferable to having numerous pole lines on the same street. "How often should meters be tested?" was a question which caused much debate. F. L. Lucas thought that once a year was as often as a small plant could afford to test meters. J. F. Gilchrist, of the Chicago Edison Co., thought that for customers having bills of $5.00 per month or less, a yearly test was sufficient. The larger the customer, however, and the more money involved the more frequent should be the tests of the meter.

Officers for the following year were then elected as follows: E. B. Hillman, president; Xenophone Caverno, first vice-president; B. H. Abbott, second vice-president; J. A. Carothers, third vice-president; E. S. Hughes, fourth vice-president; C. A. Vallette, treasurer; D. Davis, secretary. Executive committee, W. B. McKinley, H. E. Chubbuck and S. S. Davis.

ALTERNATING-CURRENT COMPENSATED VOLTMETERS.

H. W. YOUNG.

The maintaining of a constant potential on alternating-current systems is one of the most important problems which confronts the central station manager.

This is particularly true of lighting systems as the life and candle-power of an incandescent lamp are vitally dependent on the voltage supplied at its terminals. Even a slight increase in voltage above the normal greatly shortens the life of an incandescent lamp, while a decrease in voltage materially lessens the candle power. In order to obtain the best lamp life and maintain a high standard of service, it is necessary that the voltage applied at the lamp terminals be constantly maintained as near the normal as possible.

The average alternating-current station of to-day employs large generating units, each machine usually supplying several districts by means of independent feeders. The business district may be supplied by one feeder of the generator, while another feeder, from the same machine, may supply a residential district, or possibly a summer resort. The load characteristics will therefore be radically different for each class of service, and the peak will occur at different hours on the various feeders.

It will be readily seen that the amount of compounding required on any individual circuit will depend on the condition of load and thus it becomes necessary to give the best service, that some means be provided for regulating the voltage on each feeder in order that constant potential will be delivered at the lamps, regardless of load conditions.

Several forms of feeder regulators have been devised which perform this function very satisfactorily, but in order that the station attendant may correctly manipulate the regulators, it is necessary to employ a voltmeter which will indicate the pressure maintained at the point of distribution. The voltage at the point of distribution can, if the load is non-inductive, be calculated by means of the ammeter and voltmeter readings, when the resistance of the circuit is known, but this method is far from being satisfactory, and is subject to appreciable errors if the load it at all inductive.

A method employed to a large extent in the past, was to run small wires, commonly known as "pressure wires," from the feeder end or center of distribution back to the station; these wires being of sufficient capacity to operate a voltmeter without appreciable loss. Arrangements were made so that the voltmeter could be plugged across the pressure wire terminals and the voltage at the center or end of the feeder determined.

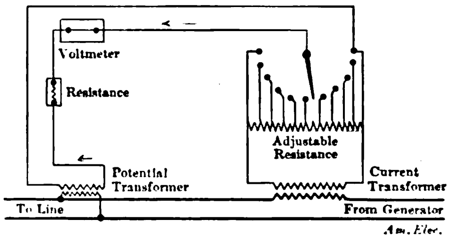

FIG. I.

This method, however, was necessarily expensive, and when carried out to any degree of completeness resulted in a great deal of complication. As the length of feeders increase the cost of installing such pressure wires becomes excessive, and in systems having feeders covering great distances the expense would be prohibitive.

In place of the older methods of calculation or use of pressure wires, a simple, inexpensive and thoroughly reliable device has been developed, by the use of which the pressure maintained at the point of distribution can readily be determined and the potential regulators properly adjusted to maintain the desired voltage.

This device is known as the voltmeter compensator and is made in two distinct types, one being suitable for use on circuits carrying non-inductive loads only, the other for use on either inductive or non-inductive circuits. Several forms of each type have been developed, but only the more important will be considered.

Fig. 1 illustrates a form of voltmeter compensator for use on circuits carrying a non-inductive load. This device consists of a current transformer, an adjustable resistance, and a small pivoted switch, the entire combination being mounted on a common support.

The primary of the current transformer

is wound with comparatively few turns of wire having sufficient capacity to safely carry the entire current of the circuit. The secondary is wound with a much larger number of turns of smaller wire, and gives across its terminals a pressure of about twenty volts with maximum current in the primary. Across the transformer secondary is connected an adjustable resistance provided with a number of taps brought out at equal distances and firmly secured to suitable contact points. A pivoted switch arranged so as to describe an arc coinciding with the contacts makes positive connection by means of a spring backing.

The station indicating voltmeter is connected through the adjustable resistance and pivoted switch, to the secondary winding of a potential transformer, the primary winding of which is connected directly across the circuit. This adjustable resistance is so connected that the drop across it is in opposition to the secondary voltage of the potential transformer, the voltmeter thus indicating the difference between the drop across the resistance, and the secondary voltage of the potential transformer.

As the drop in potential on a non-inductive circuit is directly dependent upon the current, length of line and size of wire, it will at once be apparent that, as the load increases in the primary of the current transformer, the drop across the adjustable resistance increases in direct proportion and a certain pressure is opposed to the pressure of the potential transformer secondary. As the load varies, the value of this opposing voltage increases or decreases, and causes the station voltmeter to indicate a value less than the actual bus-bar voltage. By proper proportioning of the adjustable resistance any desired range of compensation can readily be obtained. As usually supplied for commercial service the resistance is so proportioned that a regulation in 2 per cent steps is obtained. The station attendant adjusts the feeder regulator until the voltmeter indicates the correct pressure to be maintained at the point of distribution, thus eliminating the personal factor which is necessarily introduced when maintaining constant voltage at the point of distribution by the use of pressure wires, or voltmeter and ammeter calculations.

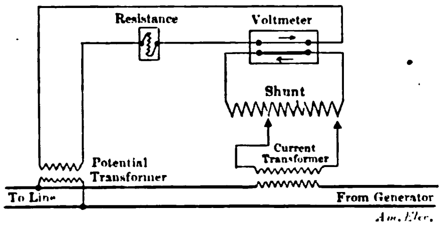

FIG. 2.

The compensator when first installed must be adjusted for the normal operating conditions of the circuit and until these conditions change no further adjustments are necessary. If the line losses are known the device can at once be set for the desired compensation, but when this factor is unknown it is necessary to take voltmeter readings at the center of distribution and adjust the compensator accordingly.

A common method of adjusting the voltmeter compensator is to have readings taken at the point of distribution where normal voltage is to be maintained and the readings telephoned back to the station. The compensator can then be adjusted until its voltmeter reading agrees with the voltmeter on the line. A few trials at different hours of the day will enable the station attendant to closely adjust the device for average conditions.

If desired the indicating line voltmeter can be replaced by a curve drawing or graphic recording voltmeter and a continuous record obtained of the voltage variation. By means of the data obtained the voltmeter compensator can be adjusted as desired.

The compensating device illustrated in Fig. 2 is of somewhat different construction and, like the compensator previously described, is suitable for use on non-inductive circuits only. This device employs a current transformer, a specially wound voltmeter and a shunt having adjustable contact points. The current transformer is external to the voltmeter and shunt, has a primary winding of suitable capacity for the circuit under measurement and a secondary winding having a capacity of approximately five amperes.

The voltmeter is provided with two windings, one consisting of several hundred turns of fine wire, the other having a comparatively few turns of wire capable of carrying five amperes continuously. The terminals of the heavier winding are brought out to binding posts across which is connected the adjustable shunt. The fine wire winding of the voltmeter is connected through an external non-inductive resistance to the secondary of a potential transformer, the primary of which is connected directly across the circuit.

The voltmeter coils are wound in opposition to each other; each coil therefore tending to decrease the field generated by current passing through the other coil. As the value of the current in the secondary of the current transformer is directly proportional to the current in the primary, it will at once be seen that a current directly proportional to the load will flow through the joint circuit formed by the shunt and heavy winding of the voltmeter. The amount of current which passes through the voltmeter portion of the joint circuit is determined by the position of the movable contacts on the shunt, which in turn are governed by the per cent of compensation desired. The indications of the voltmeter and per cent of compensation are therefore dependent upon the relative ampere turns of the two windings. Like the compensator illustrated in Fig. 1 it is necessary to adjust this device for the normal conditions of the circuit, but it requires no further attention until these conditions change.

The devices illustrated in Figs. 1 and 2, therefore, give readings on the voltmeter which decrease in proportion to the current which is in phase with the e.m.f.; but as a rule inductive drop cannot be neglected and errors of more or less magnitude are introduced. If the load is composed of incandescent lamps only, the inductance will be of small value, but if fan motors, arc lamps, inductive power motors, etc., are also connected, the inductance is correspondingly increased, and the fall of potential is no longer in proportion to the current flowing. It is necessary for such service to provide a compensating device which will enable the voltmeter to accurately indicate the pressure at all times regardless of the current or character of load. Such a device must also have means of adjustment for circuits in which the ohmic or inductive drop is variable.

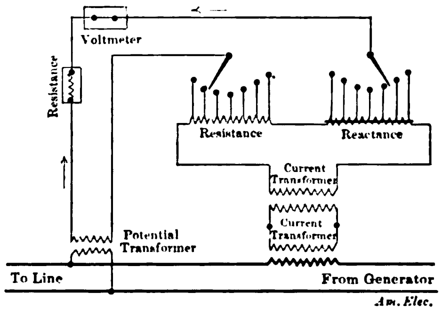

FIG. 3.

Fig. 3 illustrates a compensating device which meets these conditions. By its use the station voltmeter indicates the actual voltage maintained at the point of distribution regardless of the condition of load, that is, current, resistance, reactance and power factor all being taken into account.

The device consists of three elements as follows: A current transformer, a resistance and a reactance, both of the latter being adjustable in value. These elements are all contained in a suitable frame arranged for mounting on the switchboard.

The secondary of the internal current transformer is connected in series with the resistance and reactance, and the primary connected to the secondary of an external current transformer, the primary of which is connected directly in series with the load. This external transformer has a secondary winding giving a current of approximately five amperes and is usually one of the standard transformers operating other switchboard instruments or meters. The small internal transformer is wound to give approximately one ampere on the secondary which permits the use of small reactance and resistance coils, thus keeping the watt loss of the device at a low value.

As will be noted from the illustration, taps are brought from the reactance and resistance to small contact points over which travel pivoted switches. One switch is connected to the voltmeter and the other to the secondary of a potential transformer, the primary of which is connected across the circuit. The current and fall of potential across the resistance and reactance are dependent upon the load in the main circuit and the connections to the voltmeter are so arranged that the fall of potential across them is in opposition to that of the potential transformer, the voltmeter thus indicating the difference of the two potentials. A local circuit having characteristics practically identical to the main circuit is therefore produced, as the reactance takes care of the inductive, and the resistance of the ohmic drop. Any change in the main circuit will instantly produce a similar change in the local circuit and be immediately indicated by the voltmeter. The station attendant can then adjust the regulating devices until the voltmeter again indicates the voltage to be maintained at the center of distribution. The per cent of compensation is determined by the position of the pivoted switches more or less potential being opposed to the voltage of the potential transformer as found necessary.

The compensated form of voltmeter will undoubtedly find great favor among electrical engineers and central station managers. The devices in Figs. 1 and 2, while extremely useful are by nature of their construction necessarily limited in application, and the majority of distributing systems will require the device illustrated in Fig. 3. The fact that the compensator can be used on any system, and is accurate on varying loads, regardless of the power factor, is a feature which will appeal to all users of electrical apparatus. It can safely be predicted that but comparatively few new alternating current lighting systems will be installed without voltmeter compensators, and many of the present systems will undoubtedly also be essentially equipped with these useful devices.

CONVENTIONS OF THE AMERICAN STREET RAILWAY ASSOCIATION AND AFFILIATED ORGANIZATIONS.

The conventions of the American Street Railway Association at St. Louis, and its affiliated bodies, the American Street Railway Mechanical and Electrical Association, and the Street Railway Accountants' Association of America, were among the largest ever held by these associations, the registered attendance at the Street Railway Association's convention alone being over 1100. The sessions of the Mechanical and Electrical Association opened on Monday, October 10, with E. W. Olds in the chair. J. I. Beggs, president and general manager of the Milwaukee Electric Railway & Light Company, delivered an address and recommended the consolidation of the organization with the parent body and the reorganization of the latter. W. C. Ely, president of the International Traction Company, of Buffalo, spoke of the possibility of the parent organization taking over the Electrical and Mechanical Association and paid a high tribute to the master mechanic.

F. G. Simmons reported that trackmen were desirous of joining the association and the by-laws were accordingly changed to permit this addition to membership. In the afternoon W. D. Wright read his paper on "The Ideal Shop," which was followed by J. Millar's paper on "Wheel Matters."

At the session on Tuesday John Lindall's paper on "Maintenance and Inspection of Electrical Equipment" was read by A. Green. The author laid stress upon systems of written reports and proper tabulating and recording of defects. He also referred to the excellent results obtained by training motormen, electrical inspectors and repairmen. After the appointment of a committee on cars and car equipment, the shop, car stations, track and block signals, the association proceeded to the election of officers, which resulted as follows: President, C. F. Baker; vice-presidents, H. H. Adams, Baltimore; J. Millar, Buffalo; Fred G. Simmons, Milwaukee; secretary, W. Mower, Detroit; executive committee, B. F. Carver, Newark; J. S. Doyle, New York; C. C. Lewis, Schenectady; W. H. McAloney, Denver.

The first session of the Street Railway Association was held on Wednesday, October 12, President Francis, of the Exposition, making the opening address, to which President Ely, of the association, responded. Prof. Goldsborough followed with an address in which he pointed out the features of the Exposition of special interest to street railway men. Mayor R. Wells, of St. Louis, then welcomed the convention, after which President Ely delivered his presidential address.

In this he reviewed the important work of the electric railway field principally with respect to heavy traffic. A considerable portion of the address was devoted to the subject of the reorganization of the association. There were already two subsidiary organizations and it had been proposed to create a third having for its membership electric roadbed engineers and superintendents. President Ely thought that this could not go on indefinitely, for with a large number of organizations, each pursuing its solitary way unmindful of the others, there would finally be chaos. He therefore considered it vitally necessary to take up the matter of reorganization, and suggested that this be referred to a committee on which the several affiliated bodies would have a representative.

Several technical papers were read at Thursday's session, two of these being on the steam turbine. One was written by R. H. Rice and the other by J. R. Bibbins, and both elicited considerable discussion. Replying to a query, Mr. Rice said that the commutators of the Curtis turbine run dry, lubricating brushes being used, and that the commutator bars are secured by nickel-steel rings shrunk on over insulation. S. M. Hopkins said that in Columbus, Ohio, there was a 500-kw. turbine connected at the end of a steam line, and that while there was a large amount of steam condensed in the steam pipe, sufficient in fact to make it almost impossible to start a small exciter engine, no difficulty was experienced in starting the turbine. Comparative tests, however, made on two 500-kw. turbines and two tandem reciprocating engines showed these latter machines to be more efficient. W. H. Abbott, of Cleveland, said that his company was operating two 1500-kw. turbines with steam superheated 50° to 100°, and that water was present at times in fairly large quantities in the steam pipe. This Mr. Mailloux explained was due to water entrained mechanically. He said that turbine builders did not claim the highest economy under all conditions, and cited the case of a 5000-h.p. triple expansion, four-cylinder, Swiss reciprocating engine at Berlin, which at nearly full load had developed a horse-power-hour for something less than 9 pounds of water with superheat up to 600° or more. This engine, however, had 16 valves and complicated mechanism requiring much lubrication. There was a critical price for coal, he said, at which the turbine is not preferable to the reciprocating engine.

On motion a committee of nine members was appointed whose duty is to endeavor to increase the membership of the association. The duties of the secretary were also enlarged so as to require his entire time. The following officers were elected: President, W. Caryl Ely (re-elected); first vice-president, Elwin C. Foster (re-elected); second vice-president, John I. Beggs; third vice-president, Richard McCulloch; secretary and treasurer, T. C. Pennington; executive committee, the president, the vice-presidents and John J. Stanley, Howard F. Grant, C. G. Goodrich, Frank G. Jones and W. E. Harrington.

Abstracts from Foreign Contemporaries

Automatic Transformer Switches.—J. Schmidt describes in a recent issue of the *Elektrotechnische Zeitschrift* a transformer switch designed by the Siemens-Schuckert Works for automatically interrupting the primary and secondary circuits of a transformer whenever the current consumption on the secondary side falls below a predetermined amount. This arrangement permits a low-tension circuit to be fed by a continually varying number of transformers, the number at any instant being automatically regulated to give the most economical results. The switch contacts are mounted on three upright grooved porcelain bodies, the middle one being free to turn. Rotating this middle portion one way or the other effects the opening or closing of the switch. Springs are interposed in the mechanism in such a manner that both the opening and the closing of the contacts is done quickly. The operations of switching on and off are controlled by a device similar to that often used for regulating alternating current arc lamps. This device consists chiefly of an aluminum disc, upon which a torque is exerted by two magnetizing coils, one of which is connected in series with the secondary circuit, while the second one is energized in shunt. The torques corresponding to the two magnetizing coils are opposed to each other, and may be regulated in strength not only by varying the windings of the coils, but also by shifting their position relatively to the disc. It is obvious, therefore, that the disc may be made to turn one way or the other when predetermined conditions as to load exist. If the current in the secondary circuit drop, for instance, below a certain point, then the torque arising from the action of the shunt coil overcomes the less powerful torque relating to the series coil. Consequently, the disc turns in a certain direction, and in doing so closes an auxiliary circuit. A small magnet is thereby made to attract an armature, this in its turn causing the main switch to open against the pull of a spring. If the load in the secondary increases above a given value, the disc turns in the other direction. Another auxiliary circuit is closed, a catch is released, and the switch is closed by the force of the spring which previously had been compressed. Fig. 1 shows the switch applied to two three-phase transformers. *A*, A_1 and A_2 are high-tension feeders, *B*, B_1, B_2, *C*, C_1 and C_2 being high-tension distribution cables. The low-tension bus bar N_1 is divided into two parts *A* and A_1 the transformers being connected to the former side and the distribution lines being connected to the latter side; both halves of the bus are, however, electrically connected by the wires *l* and *m*, which energize the magnet *b* of the relay. In order to illustrate the manner in which the device works, suppose the transformer *I* to be designed for a secondary load of 100 amperes and the relay to be set for 80 amperes. Should the load fall below 80 amperes, the magnet *a* becomes more powerful than magnet *b* and the disc *c* revolves so that the contact *g* on the lever *e* makes electrical connection with contact *i*. A circuit is then completed through the transformer, conductor *G*, terminal *o*, fingers *π ρ*, terminal *σ*, conductors *G'* and 19, terminal 20, conductor 1, lever *e*, contacts *g* and *i*, conductor 9, terminal 10, conductor 11, terminal 12, electromagnet *x*, terminal 13, conductor 14, terminal 15, conductors 16 and *H*. The excitation of the magnet *x* causes it to attract the armature *w*. opening the switch, thereby cutting out transformer II.

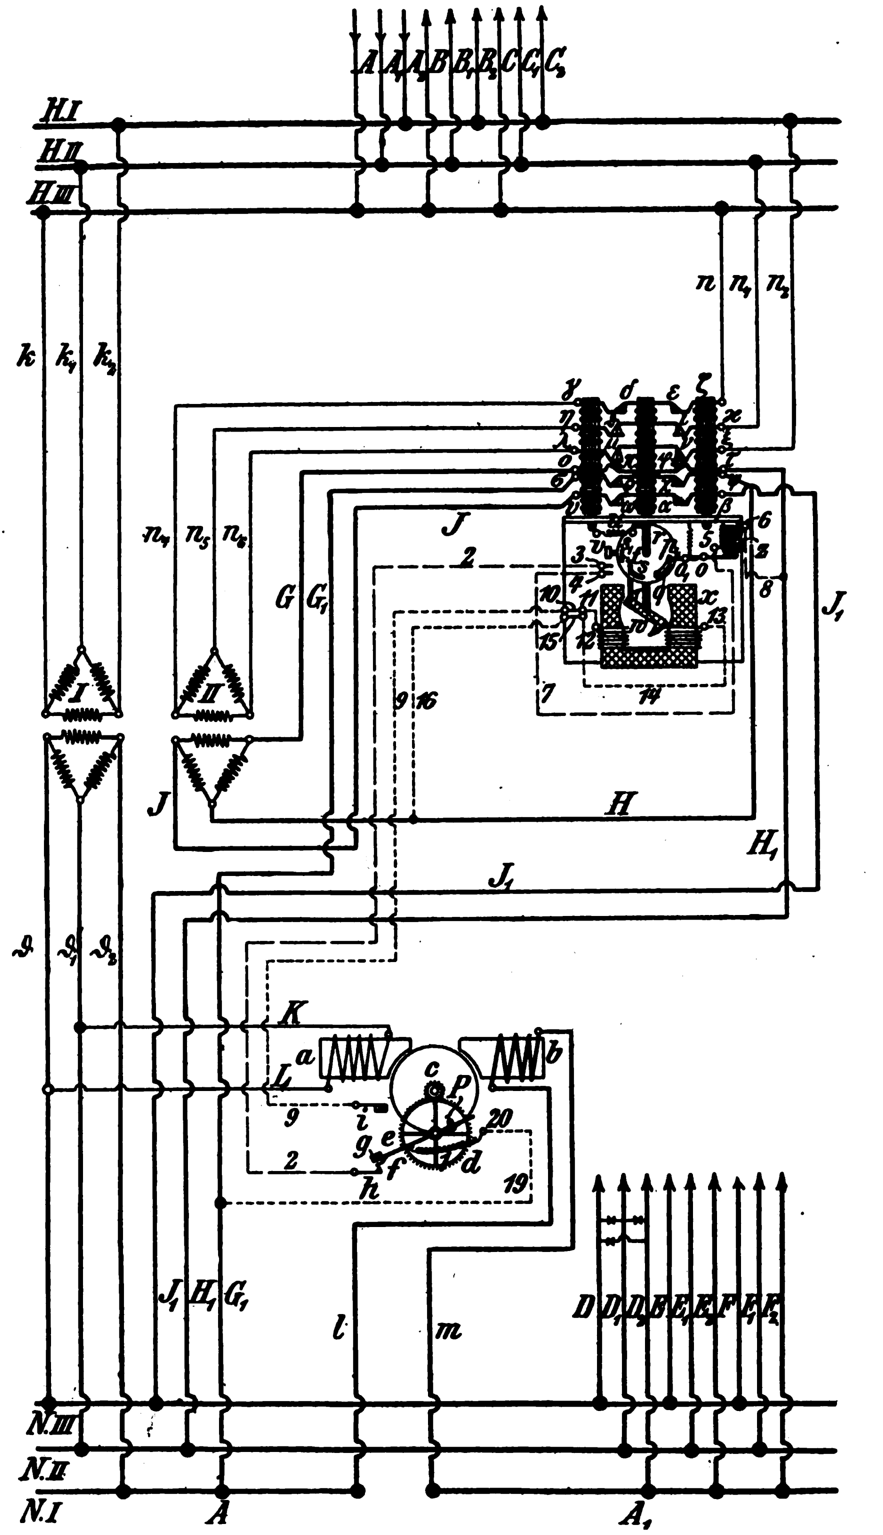

FIG. 1.—AUTOMATIC TRANSFORMER SWITCH APPLIED TO THREE-PHASE TRANSFORMERS.

Novel Arrangement of Steam Mains.—In the Willesden power house of the North Metropolitan Electric Supply Company, a description of which appears in our English contemporaries, the arrangement of the steam mains is somewhat novel. Each boiler serves one engine directly. The equalizer main does not run straight across the boilers, however, but is made up of separate lengths serving two boilers, one above the back of the boilers, the next over the center, and so on. These are joined by a connecting pipe at right angles to them through wide bends. This allows ample room for expansion of the pipe without the intervention of expansion bends, and it is the regular practice at the works to shut off the equalizer main when it is not required, in spite of which no trouble is experienced with the joints. To guard against water-hammer, a separator is placed at each connection between the equalizer main and the boiler, in addition to the separator placed, as usual, at each engine. The piping is of steel throughout. Contrary to the usual arrangement, the low-pressure cylinders, instead of the high-pressure cylinders, are nearest the boiler house. This puts the condensers in a convenient position against the wall of the boiler house, and there is, moreover, practically no extra length of steam main, as this is carried from the separator to the high-pressure cylinder through the receiver between the two cylinders, which is thus heated with live superheated steam.

A New Crossley Oil Engine.—A recent and fruitful development of the internal combustion motor is its adaption to the use of crude oils, or oils of a specific gravity that precludes their use in motors of the ordinary type. Although experiments on this kind of engine have been in hand for several years, says *The Engineer*, of London, we believe we are not far wrong in saying that it is only within the last eighteen or twenty months that really satisfactory designs have been reached. One of these is illustrated herewith, and, like all engines suitable for crude oil, provision is made for the injection of water into the cylinder before compression. This has the effect of allowing of a much higher compression without pre-ignition than is ordinarily possible, and it has other effects, which are not very fully understood; at any rate, they are frequently discussed. The engine works on the "Otto," or four-stroke cycle, and will use the crude, heavy, black petroleum oils and the semi-refined or intermediates, as well as the ordinary refined lamp oils. The consumption of fuel in these engines is, it is said, only about three-quarters of a pint per brake horse-power per hour. The working of the engine will be readily understood on referring to the accompanying illustrations. On the suction stroke of the piston air is drawn into the cylinder through the main air valve, and the oil is pumped through the oil sprayer into the vaporizer, which receives a further supply of air through a snifting valve. At the same time water is pumped through the water sprayer and enters the vaporizer. This charge is then compressed, and, as the crank of the engine passes the inner dead center, is ignited by the hot ignition tube, giving the working stroke. The exhaust valve then opens to allow the burnt charge to escape, after which the cycle of operations is repeated. The ignitions are continuous on all loads, and the ignition tube is therefore retained at the required temperature without the aid of a lamp except when starting the engine. The speed of the engine is governed by varying the amount of oil and water injected in such a manner that on heavy loads full charges of oil and water are delivered, whereas on light loads only small charges are given. Engines which ignite their charges automatically without a lamp have usually only a low compression. On this engine, however, the compression is comparatively high, the indicator cards showing 75 lbs. per square inch, and over 100 lbs. per square inch is being successfully used in some cases. Vaporizers are usually constructed with some form of cover to prevent cooling. In this engine it will be noticed that no covers are used, and that, on the contrary, cooling ribs are cast on the vaporizer to dissipate as much heat as possible by radiation. Further cooling is also effected internally by the water spray. Engines on this principle have been constructed in powers ranging from 2 to 47 brake horse-power, and larger sizes are being designed.

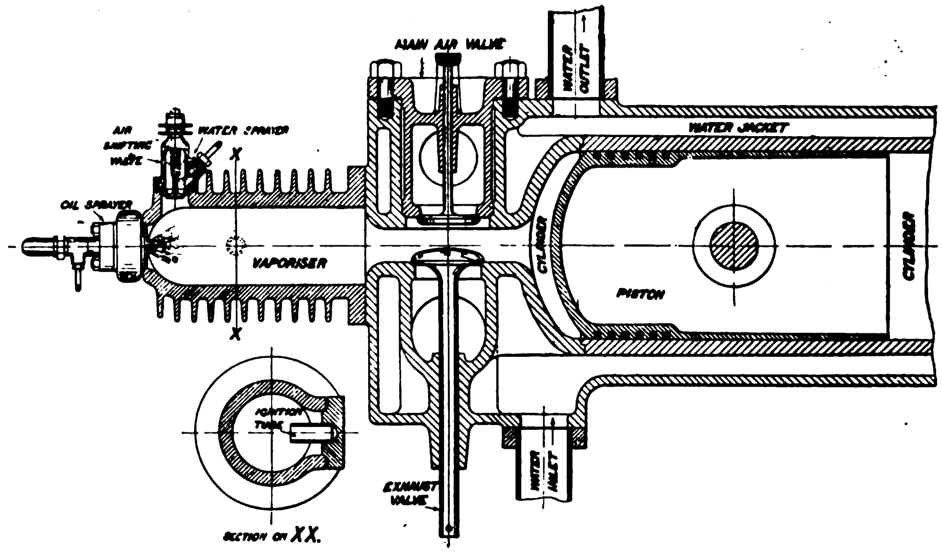

FIG. 2.—SECTION OF NEW CROSSLEY OIL ENGINE

Improvements in Gas Engines.—The London *Mechanical Engineer* describes some improvements in gas engines made by the firm of Fried. Krupp, of Essen, Germany, and patented in Great Britain. The patent relates to gas engines in which the valve chests are placed on the back of the cylinder, the object being so to construct the valve chests for such engines that splitting of the valve chests and cylinders is effectually prevented. The desired end is attained by surrounding the valve chests with a cylinder jacket in the form of a water chamber, so that they are surrounded by the cooling water, and consequently no excessive accumulation of heat can take place at any point. Fig. 3 shows, by way of example, an application of the invention to the inlet and outlet valves of a double-acting, four-stroke cycle engine. The working cylinder, *A*, which is surrounded by the cylinder jacket, *B*, has at each end upon its back a flanged junction, a_1. Upon each of these junctions is mounted a valve chest, *C*, of trough shape, and having a corresponding junction, c_1. At the other end the chests are provided with ribs, c_2, which bear against ribs, a_2, of the cylinder, but are not rigidly connected thereto, so that the chests, *C*, can expand freely during fluctuations of temperature. The chests, *C*, are closed above, with the exception of the openings in each for one inlet valve, *D*, and one outlet valve, *E*. The cylinder jacket, *B*, extends as far as the valve boxes, D_1E_1, and thus forms a space surrounding the chest, *C*, in which the cooling water can completely pass round it, so that no excessive accumulation of heat is to be feared.

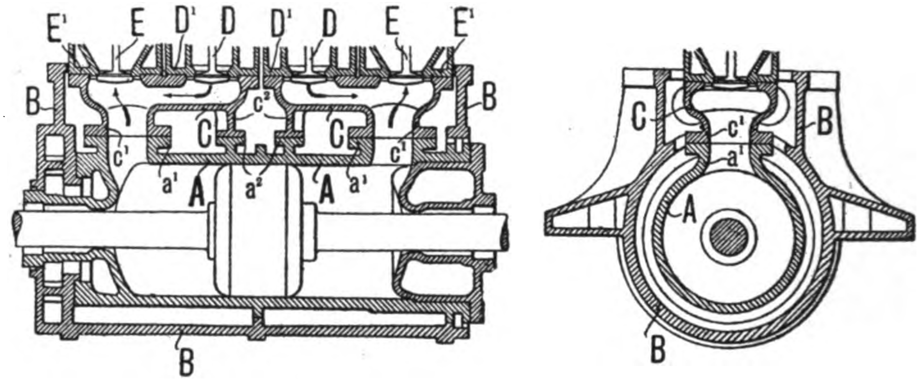

FIG. 3.—CYLINDER OF DOUBLE-ACTING, FOUR-STROKE CYCLE GAS ENGINE.

A New Cable Grip.—A novel manner of drawing cables is described in a recent number of *The Electrician*, of London. The cable grip is shown by Fig. 4; 7/22 galvanized-steel wire is used in its construction and it enables the cable to be drawn without the lead sheathing being cut, as is usually the case. Most engineers will at once appreciate the enormous strain upon the grip which holds on with such tenacity that either the rope or the cable will have to give way before a failure in drawing can occur, as, on account of the construction of the grip, the greater the pull the more securely it holds. Although the severest strains have been put upon the grips they have given every satisfaction, and have come out of the ordeal successfully.

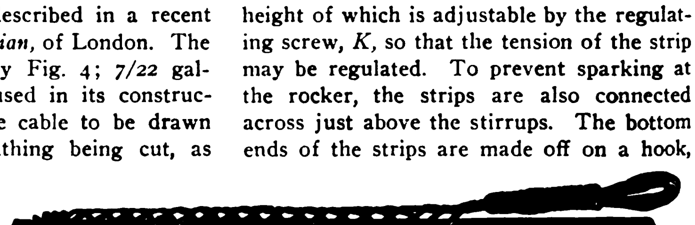

FIG. 4.—NOVEL CABLE GRIP.

New Arc Lamp With Hot-Wire Control.—The London *Electrician* describes the latest form of Foster arc lamp shown by Fig. 5 herewith, the distinctive feature of which is the hot-wire control in place of the ordinary solenoid control, which enables the lamp to be used on either alternating or direct-current circuits. The current enters at the positive terminal, shown dotted, and passes down the lead, *S*, to the post, *V*. To this post there is attached two pairs of metal strips, *R R*, the expansion and contraction of which control the feed of the carbon. The upper ends of the strips are fixed to the stirrups, *N N*, which are hung from the rocker, *M*, on the post, *L*, the height of which is adjustable by the regulating screw, *K*, so that the tension of the strip may be regulated. To prevent sparking at the rocker, the strips are also connected across just above the stirrups. The bottom ends of the strips are made off on a hook, *T*, from which connection is made by a flexible wire, *D*, covered with glass beads, to the upper carbon holder, *Q*, which is free to slide in the tube, *P*. This carbon holder is merely a split tube, and the positive carbon is simply pushed home into it. The circuit from the negative or lower carbon is through the carbon holder, *Y*, the bottom rods, *H H*, and the negative lead, *A*, to the negative terminal. When current is turned on, the strips expand; and, as the bottom hook, *T*, is fixed to the end of a rigid strut, *B*, pivoted at its top end, the hook is pulled over to the left by the spring, *C*, acting through the disc, *F*, and the link, *E*. As the disc rotates it moves the lever, *U*, shown dotted in the drawing, and this brings into action the clutch, *W*, lifting the positive carbon and striking the arc. There is a certain amount of play between the link, *U*, and the disc, *F*, so that the wire is allowed to attain a fairly high temperature before the arc is struck. With a diminished current the heated strip shortens and the disc is turned back slightly, allowing the carbon to feed. Should the feed of the lamp prove to be too fast or too slow in working, this may be adjusted by turning the screw, *K*, already referred to, by means of which the tension of the strip can be slightly varied. It may be noted that the lamp is entirely fireproof in construction, and that it contains no solenoid or dashpot. A steatite ring, *G*, held in place by the screwed bush, *X*, guides the upper carbon, *N*, when the lamp is trimmed, and the clutch is lined with the same material. To facilitate trimming, the pointed end of the carbon is used uppermost. The lamp is of the single-globe pattern, the arrangement of the globe carrier, *Z*, and globe dashpot, *J*, to prevent air leakage being clearly seen in the drawing. The illustration being to scale, it is seen that the lamp is small and compact; its weight is only 12 pounds.

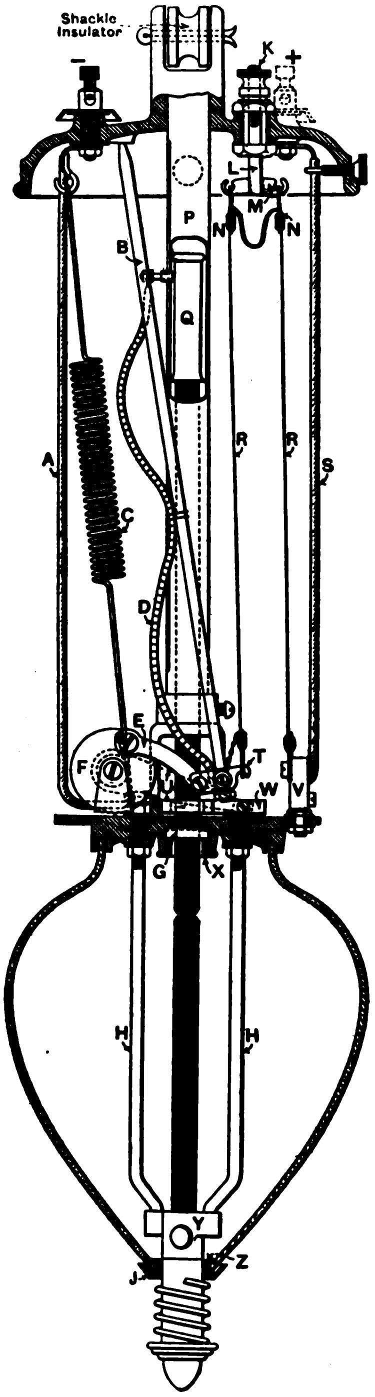

FIG. 5.—FOSTER ARC LAMP.

SOME RECENT ELECTRICAL PATENTS

Remote Switch Control. — Fig. 1 herewith illustrates diagrammatically a rather ingenious system of remote control for switches, applicable, however, only to a three-wire system of supply and patented by John L. Hall nad Howard R. Sargent, of Schenectady, N. Y. At each switching point is located a polarized relay, *C*, which controls the exciting circuits of a double magnet, *B*, adapted to close and open a switch, 15, according to the excitation of the windings. The polarized relays are all connected in series between the neutral wire of the distributing system and the middle point of a two-way single-pole switch, *A*, located at the station or other point of control. Closing the switch, *A*, in one direction will send current of one polarity through the polarized relays, causing each of them to close one of the magnet exciting circuits; if the relay armatures close to the left, the upper coils of the magnets will be energized and the disc-shaped armatures will be raised, opening the switch contacts, as shown in the diagram. Closing the switch, *A*, in the opposite direction puts current of opposite polarity through the relays and they then close the exciting circuits of the lower magnet coils, causing the magnets to close the switch contacts. When the switch, *A*, is open, the relay armatures are held in the mid position by springs. The weight of the switch arm, 11, is sufficient to hold the magnet armature up and keep the contacts open after the magnet has operated, and when the

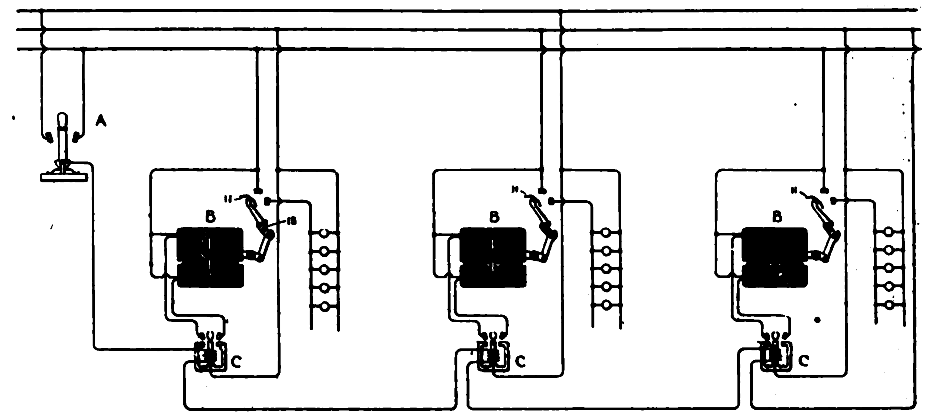

FIG. 1.—REMOTE SWITCH CONTROL FOR THREE-WIRE SYSTEMS.

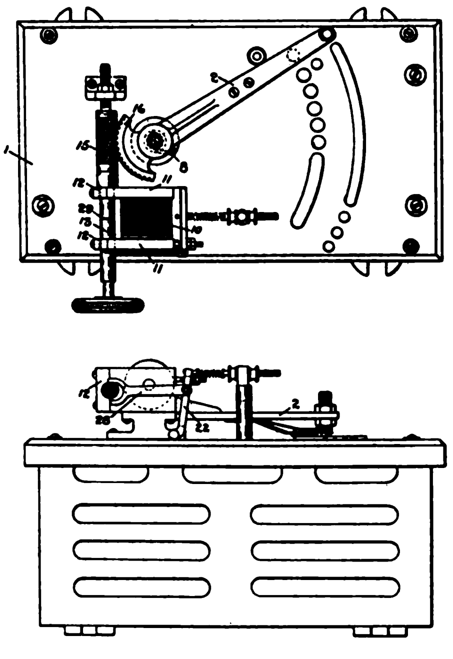

FIGS. 2 AND 3.—MOTOR SPEED CONTROLLER.

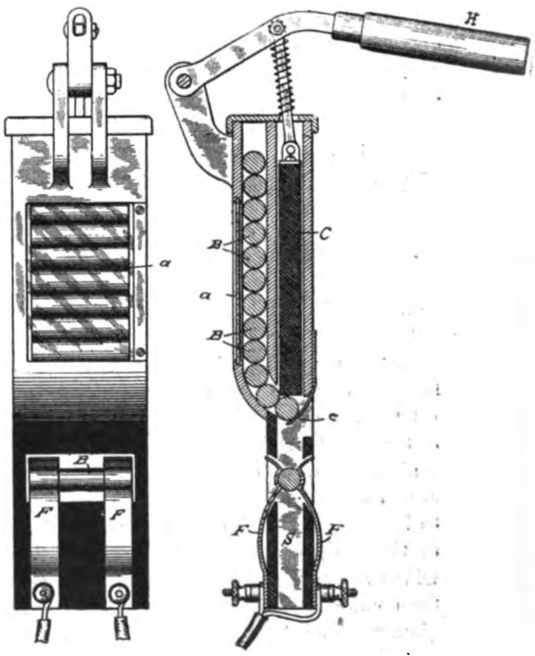

FIG. 4.—MAGAZINE FUSE BLOCK.—FIG. 5.

switch has been closed by the bottom magnet coil the toggle is in a straight line and therefore holds the switch closed after the magnet coil has been de-energized. Consequently it is unnecessary to keep the switch, *A*, closed in either direction. Patent No. 766,391.

Motor Speed Controller. Figs. 2 and 3 illustrate a form of motor speed-regulating controller having automatic overload and undervoltage release that has been patented by M. M. Wood and Henry Geisenhoner, of Schenectady, N. Y. The rheostat arm, 2, is moved by means of a spiral gear, 15, on a transverse shaft, and a segmental rack, 16, on the heel of the arm. The transverse shaft, 13, is of magnetic material in two parts, which are joined mechanically by a non-magnetic piece, 29, set in. This is to prevent the shaft from short-circuiting the poles, 11, 11, of the magnet, 10, to which it is partly journaled. The journal caps, 12, are of brass, so that the magnet poles pull the shaft, 13, tightly against their halves of the two journal boxes. The magnet coil is connected, presumably, in the motor armature circuit. The arm, 2, is provided with a retracting spring, 8, which tends to throw it to the "off" position. While the motor is operating normally, with the arm, 2, in any position of its travel, the magnet holds the shaft, 13, against its poles and thereby prevents the spring, 8, from pulling the arm, 2, to zero. Should the circuit be opened, the mechanism is, of course, released and the arm is returned to zero. Should an excessive current flow in the motor circuit, the magnet attracts the armature, 22 (see Fig. 3) and by means of the bifurcated lever, 28, pushes the shaft, 13, away from its poles, relieving the friction at the journals and allowing the spring to return the arm, 2, to zero, or the "off" position. Patent No. 771,958.

Magazine Fuse-Block.—Several forms of magazine fuse block have been devised, some in which the melted fuse is replaced automatically by semi-automatic apparatus actuated manually. The present invention belongs in the latter class, and is adapted for the use of enclosed fuses. The inventor is Herbert G. Addie, of Cresco, Iowa. Fig. 4 shows a front elevation of the magazine and Fig. 5 a vertical section from front to back. The fuses, *B, B*, etc., are contained in the front compartment of the magazine, which has a glass window, *a*, through which the condition of the supply may be seen at a glance. The "live" fuse is held between metallic clips, *F, F*. When it blows, the handle, *H*, is depressed, causing the plunger, *C*, to push the lowermost fuse, *e*, in the magazine downward and between the clips, *F, F*. The entrance of the fresh fuse into the clips forces the spent fuse out and it drops through the slot, *S*, out of the case. Patent No. 772,200.

CENTRAL STATION ENGINEERS.

I.

John William Lieb, Jr.

John William Lieb, Jr., was born in Newark, N. J., on February 12, 1860. His early education was acquired at the Newark Academy and at the Stevens High School, Hoboken, N. J. In 1880 he graduated from the Stevens Institute of Technology, receiving the degree of Mechanical Engineer. Immediately after his graduation he entered the employ of the Brush Electric Company, of Cleveland, Ohio, as a draughtsman. He remained here less than a year, entering the employ of the Edison Electric Light Company, of New York, in a similar capacity in 1881. In 1882 he was transferred from this company to the experimental department of the Edison Machine Works. He assisted in the tests of the first "Jumbo" direct-connected Edison dynamos, and was put in charge of the installation of the electrical equipment of the old Pearl Street Edison station by Mr. Edison, Mr. C. L. Clarke being chief engineer at that time. Mr. Lieb assisted in the tests and experiments incident to the starting up of this pioneer station, the first commercial station in the United States to supply current for incandescent lighting and power from an underground system, and on the inauguration of regular service September 4, 1882, under the auspices of the Edison Electric Illuminating Company, of New York, was appointed its chief electrician.

JOHN WILLIAM LIEB, JR.

A syndicate of Italian capitalists, with Prof. Colombo as technical adviser, having purchased the complete equipment of boilers, engines, dynamos and Edison underground system for Milan, Italy, Mr. Lieb was selected by Mr. Edison to direct the installation. The Milan station, equipped with B. & W. boilers, Armington & Sims engines and Edison "Jumbo" dynamos, began regular service in 1883 and Mr. Lieb remained in charge as manager on the organization of the Italian Edison Company. He was appointed in turn its chief electrician, director of stations and chief engineer in general charge of the technical department of the company, engaged in manufacturing electrical apparatus, installing isolated plants and constructing and operating lighting and power stations throughout Italy.

Mr. Lieb's company was among the very first to exploit the alternating-current system, beginning with a plant in Milan, Italy, in 1886, and using also the Thomson-Houston arc light system extensively. His last work in Italy was in the electric railway field in connection with the installation of the trolley system in the city of Milan.

Offered an appointment with his old company—the Edison Electric Illuminating Company, of New York—he returned to New York in 1894, at first in the capacity of assistant to the vice-president, and advancing by steps to third vice-president and general manager. On the consolidation of various lighting interests in New York City, under the corporate name of the New York Edison Company, Mr. Lieb was appointed third vice-president and associate general manager, which position he now holds. He is also president of the electrical testing laboratories and director in several electrical corporations.

Mr. Lieb is president of the American Institute of Electrical Engineers, a member of the council of the American Society of Mechanical Engineers, a member of the American Society of Civil Engineers, past-president of the Association of Edison Illuminating Companies and the New York Electrical Society, second vice-president of the National Electrical Light Association and member of a number of national and foreign technical societies.

NOTES.

Ohio Society of Mechanical, Electrical and Steam Engineers will hold its ninth annual meeting at Canton, Ohio, on November 18 and 19. Ten papers of practical engineering value are to be read, and there will be interesting topical discussions. Visits will be made to the factories of the Dueber-Hampden Watch Works and the Russell Engine Company at Masillon.

Revision of the National Electrical Insurance Code.—The annual meeting of the Electrical Committee of the Underwriters' National Electric Association will be held at the rooms of the New York Board of Fire Underwriters, 32 Nassau Street, New York, on Wednesday, December 7, 1904, at 10 a.m. As in the past, the meetings will be open to all interested in the matter of rules for the installation of electric wiring and apparatus as contained in the National Electrical Code. Reports of committees and all suggestions for changes in the Code to be acted upon at this meeting should be in the hands of the secretary by November 5, in order that they may be put into print for the meeting.

A Highly Novel Method of paving the way for new business has been adopted by the Denver Gas & Electric Company. A series of cards, each containing some error in spelling or diction or an obscure verse, is mailed to persons whose patronage is desired. This is followed up with a circular letter calling attention to the cards and stating that a representative of the company will call at any time named by the recipient and will present him or her with a souvenir spoon for any error detected in the matter on the cards. A postal card is enclosed with this letter on which the prospective customer has only to fill out the appointment and signature. It is needless to say that, when the representative calls, he does not put in every minute of his time congratulating the householder on the detection of errors in spelling or diction.

The Pratt Institute Free Library, Brooklyn, N. Y., has just opened to the public an applied science reference room, devoted to technical and trade literature. It is desired to make this department as useful as possible to the practical men engaged in the various trades and industries. The room contains books, bound periodicals and current periodicals. It is in charge of Mr. Herbert L. Cowing, a graduate of the Mechanical Engineering course of Cornell University. The room is open every day from 2 till 6, and on Monday, Wednesday and Saturday evenings until 9.30. A cordial invitation is extended to all who are interested. The management wishes to form a collection of trade catalogues and bulletins bearing upon all branches of industry. These catalogues will be accessible to the public, and it would be glad to receive them from any of the advertisers in or readers of the AMERICAN ELECTRICIAN.

A New Process of Electrical Rail Welding.—The Accumlatorenfabrik A. G., Hagen, Westphalia, is developing a process of electric rail welding patented by Mr. Pahdi, which unlike American methods involves the use of electric arcs produced between a rail that is connected to one terminal of the electrical circuit, and a carbon electrode connected to the other terminal. No metallically-clean welding surfaces are necessary and no riveting of the rails is required. Two carts are sufficient to carry out the process, one of the carts containing a railway motor fed from the aerial line at 550 to 600 volts and driving a dynamo of 65 volts e.m.f., while the other cart carries a "buffer" battery connected in parallel to the dynamo and proportioned so that only about 30 amperes can be drawn from the aerial wire in welding. Cables convey the current to the welding point, where a thin wrought iron plate 9 cm. (3.5433 ins.) in length with lateral bolt staples is placed beneath the lifted rail joint and the joint filled up with a little surplus on top. The material of the rail foot is afterward melted together on both sides with the plate placed below by means of the electric arc, while adding some Swedish charcoal iron. After next surrounding the rail head with two small iron moulds, melting the material of the rail head over a breadth of about 3 mm. (0.118 in.) and supplementing the deficit by Swedish charcoal iron and finally by small ingot iron pieces, a dense welding is obtained by hammering from above. About 3.5 kgs. (7.7 pounds) of additional material is used at all. Between the head and foot weld a place is left free so as to prevent any existing crack from passing throughout the whole. About 40 minutes is required for making a weld, and the power taken is 15 kilowatts. A paper recently read before the Association of German Engineers stated that about 500 welds which have given entire satisfaction have been made since July of last year. Tests are said to have shown the strength of the material at the weld to be practically equal to that of the sound rail.

A Splendid Address was delivered by Mr. Walter C. Kerr to the graduating class of Stevens Institute of Technology at the commencement exercises this year. The address constitutes one of the best advisory efforts of which we have knowledge. Following are a few extracts from it:

"We hear much about opportunities. They are everywhere plentiful. Remember, that your opportunity is the little one that lies squarely in front of you, not the larger one which you hope to find farther along. Many a man is surrounded with opportunities who never seizes one. There are traditions that Adam, William Tell and Sir Isaac Newton each had an affair with an apple, but with different results."

"Your first duty is always to that which lies across your path. The only step which you can take in advance is the next one. This leads to a simplicity of action which is commendable. Don't ramble."

"Cultivate singleness of purpose. This is more important than you may think. It is intuitive with the comparatively ignorant, and often absent in the highly trained. We are frequently surprised at the great competency of the ignorant contractor or foreman, on whom judgment is often passed by saying that he is a practical man and gets results. Analysis will show that his best quality is singleness of purpose, which leads him to vigorously do the one thing before him, without distraction following from knowing or thinking about too many other things."

"When you are getting what you go after, get it all. Avoid the mediocrity of compromise. Be thorough and stand for full competency in everything, from main essentials to details."

"Much of our engineering is only done once, and it must be done right that once. A man who has learned by experience to do a thing deserves no credit for doing it right. He is then only a repeating machine. Real power is characterized by ability to perform right the first time that which a man never did before. Such performance involves the power to assimilate and adapt experiences, of more or less like or unlike kind, in a way to bring forth correct results. This is the true use of experience, wherein a man is a thinking, active power, and not a mere repeater."

"A point of view is involved in the power to rationalize. This is a thing which each man does for himself in his own best way, and its essence consists in asking one's self whether the thing is reasonable. It is a great check upon error. It is the power of the human mind, after performing in more or less systematic and conventional ways, to stand off and look at results and ask one's self whether they are reasonable. One man will figure that certain material weighs two hundred tons, and believe it. Another will say that there is something wrong in that, for it all came on two freight cars."

"It is well for a young engineer to cultivate his vocabulary, and learn to use words in their right sense. They are then usually understood, even by those who have less knowledge. * * * * * Engineering documents, specifications and letters are full of misstatements due to the careless use of language. Conciseness cannot be overestimated. Brevity is desirable, but not at the expense of clearness. Conversely, a certain degree of facility should be acquired in reading the words of others."

"One of the worst attributes in engineering, and which is fundamentally born of conceit, tends to fasten error, censure and responsibility on others. There are times when a man needs to stand himself up in front of himself and ask: 'What is the matter with me?' The capacity of any man to admit his own error and frailty of judgment is a measure of strength rather than weakness."

"When you start your practical work, you will doubtless try to improve things. That is a legitimate purpose, if not overworked. I am not going to attempt to tell you what needs improvement, but the one improvement that most things need is in the line of sufficiency. You can think this over for yourself and apply it where it fits."

"Remember, that all the good you accomplish is going to come out of yourself. You cannot borrow it and you cannot make it out of that which has been poured into you by education or otherwise. All that you receive is only a certain quantity of knowledge, acquired by education, experience or other training, which will have a certain influence upon what comes out of yourself as your own. It is the inherent capacity to perform with your own brain which will make you what you become, and not the mere transmission of that which you have acquired. * * * * * Some have gone through experience without acquiring it, and many a man who has received an education has not got any because he allowed it to be a thing apart from his personality, and it slipped away."

The address, which is entitled "The Point of View," has been reprinted in pamphlet form, and young engineers who are fortunate enough to be in a position to obtain a copy should by all means do so.

ESTABLISHED 1889.

American Electrician

A Journal of Practical Electrical and Steam Engineering.
WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Published on the first of each month by the
McGraw Publishing Company,
114-118 Liberty Street, New York.
Telephone Call, - - - 7606 Cortlandt.

Branch Offices:

Successful Central Station Men.

On another page of this number we print the first of a series of biographical sketches of men who have been notably successful in central station development, the subject of this first biography being Mr. John W. Lieb, Jr., the well-known assistant general manager of the New York Edison Company. It may be well to state just here that these biographical articles will be found quite different from the merely complimentary sketches so frequently printed as biographies. The chief object in publishing these articles is to familiarize our readers in general with the actual careers of the men who form the subjects of them and in particular with the factors which have entered most largely into the success of those men; not to indulge in mere laudatory phrasing, which, we feel sure, not only would be little appreciated by our readers but would be offensive to those who have kindly consented to the publication of the facts concerning themselves.

◆ ◆ ◆

Electro-Pneumatic Control Apparatus.

The combination of electromagnetic and pneumatic mechanism for operating switches and other apparatus controlled from a distance and requiring considerable power for the operation is an alluring one. It has been employed with conspicuous success in a few instances, such as the control of railway motors and of smaller machinery, where compressed air was necessarily at hand for other purposes, but so far as we know no one has been bold enough to put into commercial use an electro-pneumatic control system where the air-compressor, tank, etc., would be otherwise unnecessary. There are several classes of work in which such a control system appears to be applicable to advantage, such as heavy duty hoists, freight elevators, relay-operated switchboards, etc.

In the case of motor control, with the exception of railway motors, the most convenient arrangement would seem to be the driving of the air-compressor directly by the controlled motor. The control apparatus being naturally located upon or very near the controlled motor, this arrangement would result in the maximum concentration of the involved mechanism, and the use of air-driven pistons for operating the various switches obviously would reduce the electromagnetic mechanisms to small magnets opening and closing balanced pneumatic valves; it would, moreover, greatly reduce the space occupied by the control apparatus and the vulnerability of it. Those familiar with the subject know that an electromagnet capable of exerting considerable power through a range of an inch or two is a ponderous, clumsy affair and liable to be disabled by the most trivial accident. On the contrary, pneumatic cylinders and pistons of great power occupy relatively small space and can be made extremely rugged within that small space; and the magnets to actuate the valves can, because of their smallness, be made very reliable by the use of extra insulation, wires of substantial size, and moderate dead resistances in series with them to reduce the inductive discharge due to opening the circuit.

The case of switchboard operation might or might not be one in which facilities for compressing and storing air would be otherwise unnecessary; in stations equipped with a compressor and system of pipes for cleaning purposes, it obviously would not. Where such compressed air equipments are not in use, it would in all probability be profitable to put in pneumatic apparatus for both cleaning purposes and for actuating high-tension or other heavy-duty switches. The many advantages obtainable by the use of pneumatically operated switches on the main boards, controlled electrically from the attendant's bench, will be apparent to all switchboard construction engineers.

◆ ◆ ◆

Balancing a Three-Wire System.

There are in commercial use at least two methods of balancing a three-wire, direct-current system supplied from generators of the over-all voltage of the system; one is to provide a motor-balancer consisting of two machines exactly alike connected in series and rigidly coupled together, the extreme terminals of the pair being connected to the outside conductors of the system and the junction between the machines being connected to the neutral conductor; the other is to provide two auto-transformers for each generator, the terminals of each being tapped into the armature winding at points between which maximum difference of potential occurs periodically, the points of connection for one transformer lying half-way between the points to which the other transformer is connected. This latter arrangement changes an ordinary generator into what is popularly termed a "three-wire" machine. The neutral conductor of the system is connected to the middle point of each auto-transformer. There is a third method which is practical under some conditions of operation; that is to connect a battery of storage cells between the outside wires of the system and connect the neutral conductor to the middle point of the battery.

It is impossible to lay down any general rule as to the choice between the three methods of balancing indicated above, but it may be of interest to consider the practical features of each of them. The motor-balancer presents the very considerable advantage of necessitating only two balancing sets for an entire station, one active and the other alternative. It also has the advantage that it can be compounded to compensate for the drop in the neutral conductors to the system. It has, however, the disadvantage of adding to the machinery of the station, requiring at least some care and attention. The more reliable it is, the less attention will it receive, and when any abnormal condition does arise it is very likely to go unnoticed until the balancer either breaks down or reaches a state necessitating immediate and expensive repairs. If it is not reliable enough to incur this risk, it will require so much attention as to be a nuisance and probably a source of excessive expense. It is entirely too much to expect that a motor-balancer can be so constructed as to require just enough attention to escape both of these extremes.

The auto-transformer "attachment" of a three-wire generator possesses the immense advantage of being inert mechanically. It has the additional advantage of occupying such a small space, relatively, as to make it possible to insulate its conductors beyond the remotest probability of puncture from ordinary causes. Where only one generator is in use, the auto-transformer has the advantage of low first cost; in all cases it has the advantage of low maintenance cost. It entails the disadvantage of a divided series winding on the generator in order to "compound" for an increase in the load on either side of the neutral. Where several generators are operated in parallel, this arrangement of series windings complicates the equalizing connections. There is also the slight drawback that the generator cannot be made to compound accurately for increases in the load on each side of the neutral and also for increases of equal value on both sides simultaneously, because of the drop in the neutral conductors when the load is unbalanced. Then there is the expense of providing an auto-transformer for each governor instead of being able to use a single balancing apparatus for the whole plant, as in the case of the motor-balancer.

The storage battery balancer has conspicuous operating advantages; used in connection with a suitable booster, it can be made to balance the system perfectly for any changes of load, without the use of series windings on the generators, and also to take the peak of the load and thereby reduce the amount of generator capacity required. Without the booster it is capable of balancing the system practically as well as the auto-transformer and, of course, of taking the load peak; under most conditions, however, storage battery operation without a booster can scarcely be considered satisfactory. A battery balancer is heavily handicapped by the enormous space it occupies and by the constant and highly skilled attention demanded by it in order to obtain reasonably efficient results. The expense of installation, also, is out of all proportion to that of either of the other types mentioned, and it adds to its own disadvantages those of the motor-balancer by requiring a booster. Except in stations where it would pay to instal a battery as an auxiliary regardless of balancing the distribution system, it is practically certain that a battery balancer cannot compete with either the motor or the auto-transformer.

Magnet Windings.

At least once before, and possibly more than once, we have pointed out the fact that the theory advanced in most text books to the effect that the convolutions of each layer of a magnet coil "bed" in the creases formed between adjacent convolutions of the preceding layer cannot possibly be true of coils wound in the ordinary continuous manner. From the receipt of numerous inquiries as to the allowance that should be made for this imaginary bedding we judge that the previous explanations of the matter have not reached all of our present readers; hence the following remarks.

Unless all the layers of a magnet coil start from the same end of the coil, which is manifestly impracticable, the crease between adjacent convolutions, due to the convexity of that part of each that is left exposed, is necessarily a right-handed spiral in one layer, a left-handed spiral in the next layer, and so on. It is obvious that concentric right-handed and left-handed spirals cannot mesh or bed with each other any better than the threads of a right-handed nut can mesh with those of a left-handed screw. Consequently, no allowance should be made for the bedding of magnet coil convolutions. However, the thickness of a given number of layers will be slightly less than the width of the same number of convolutions side by side, no matter how closely the successive convolutions may be wound. The reason for this is that the tension put on the wire in the process of winding compresses that part of the insulation on the wire which separates the wires of contiguous layers and draws the successive layers into much more intimate contact than that between the adjacent convolutions of a layer. An allowance of 2 per cent for the compression of insulation is ample in the case of double cotton covered wires of ordinary sizes—say No. 8 to No. 20, B. & S. gauge.

A feature of constant-potential magnet windings which also is not always grasped by the student is that the magnetizing power of a coil depends upon the average length of one turn, the voltage at the terminals and the size of the wire. Within practical limits the length of the coil parallel with the magnet core has no influence over its magnetizing power so long as the terminal voltage is unchanged. The coil length determines the amount of current required to produce a given magnetic effect and also the extent of the heating of the coil, the size of the wire having been determined. On the other hand, the magnetizing effect of a coil supplied with a certain fixed current depends only on the strength of that current and the number of turns in the coil. The size of the wire in the coil and the average length per turn have no influence on the magnetic results, but they determine the voltage at the terminals of the winding and, consequently, the number of watts expended and the heating produced, the number of turns being fixed.

Electricity in Mining.

From expressions of opinion recently given out independently by several experienced engineers it would appear that the application of electricity to mining operations has not been carried to anything like the extent that the possibilities of the field would justify. We confess considerable surprise at finding this opinion held by the men who have expressed it. There is certainly no lack of enterprise in this direction by American manufacturers; one can buy highly developed electrical apparatus for performing every mining operation that can be economically performed by machinery of any kind. If such apparatus is not used in every place where is could be applied to advantage, it would seem that some vigorous educational work among mine superintendents might be done profitably.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

In the previous article we found, in "roughing-out" a 5-h.p., 220-volt motor to run at 1000 r.p.m., that a polar bore of 8 ins. was sufficient according to the preliminary formula, but that the required number of wires could not be got into that diameter. In such a case, the proper procedure is as follows:

Ascertain how many slots the armature core will take without violating Rule V; this will enable one to ascertain the maximum number of wires than can be put on the core. Then, by means of formula 3, find out what the armature speed would be with this number of wires. Multiply this speed by the "corrective constant" opposite the polar bore in Table II; divide the product by the speed at which the armature should run. The result will be the corrective constant corresponding to the proper diameter of polar bore to be used. Applying this method to the case in hand: If we make the total tooth widths equal to the polar bore (8 ins.), this will leave 8.49 ins. of the tooth-root circle (see Fig. 3) available for slots, and as the slot for No. 13 wire is 0.21 in. wide, we can get in 8.49 ÷ 0.21 = practically 40 slots. These will hold 480 wires, and according to formula 3, the speed would be

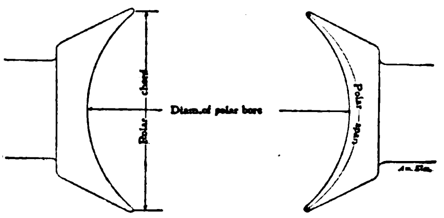

FIG. 1.

$$\frac{1000 \times 220}{0.2325 \times 480} = 1948.7 \text{ r.p.m.}$$

The "corrective constant" corresponding to 8 in. polar bore is 699.4, and this multiplied by 1948.7 = 1,362,900. Dividing this product by the desired speed of 1000 r.p.m. gives 1362.9 as the corrective constant for the proper diameter; reference to column 8 of Table II (second section) shows that 1362.9 falls between 1358 and 1413; consequently, the proper diameter of polar bore will be between 9⅞ and 10 inches. The smaller value may be taken, because 1362.9 is much nearer to 1358 than to 1413.

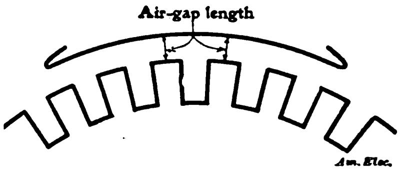

FIG. 2.

Preliminary Formulas:

K_p = Armature watts ÷ r.p.m. (1)

E.m.f. = K_e × wires × r.p.m. ÷ 1000 .... (2)

R.p.m. = 1000 × e.m.f. ÷ K_e × wires (3)

K_e = Constant for voltage corresponding to a given diameter of polar bore (See Table II.)

K_p = Constant for power corresponding to a given diameter of polar bore (See Table II).

The diameter of the polar bore being 9⅞ in., the air-gap, according to Table III, will

TABLE I.—Armature Current and Watts.

20	16500	150 ÷ p*	37.5	33.	16.5

*p = number of field magnet poles.

In 110-volt dynamos of more than 10 kilowatts, the current per armature wire is the delivered current multiplied by 1.05 and divided by the number of field magnet poles.

In all other dynamos, the current per wire is the delivered current multiplied by 0.55.

be ⅛ in.; consequently the armature core will be 9⅝ in. diameter over the teeth. With this air-gap, the coil slots could be made 0.29 in. wide without violating Rule II, and thus two wires could be put side by side in a slot instead of singly, as previously. This will allow still further readjustment of the diameter and enable the latter to be reduced somewhat. Slots 0.29 by 1 5-32 in. will take 2 × 12 = 24 No. 13 wires each. The diameter of the circle at the tooth roots will be 9⅝ — 2 5-16 = 7 5-16 in.; the circumference of this circle is 22.97 in.; the sum of the tooth-root widths must equal the polar bore (9⅞ ins.) and this will leave 22.97 — 9.875 = 13.1 in. for the sum of the slot widths. The maximum allowable number of slots, therefore, will be 13.1 ÷ 0.29 = 45. There are 24 wires per slot, so that the total number of wires will be 45 × 24 = 1080. According to formula 3, the speed would be

$$\frac{1000 \times 220}{0.3698 \times 1080} = 550.85 \text{ r.p.m.}$$

Multiplying this by the corrective constant for 9⅞ in. diameter, we get 550.85 × 1,358 = 748,054; dividing this by the desired speed of 1000, we have 748 as the corrective constant for the desired polar bore; Table II (second section) shows that the corre-

Instructions for "Laying-out" the Armature.

A.—Find the value of Kp by formula 1. Find the corresponding polar bore in Table II; jot it down.

B.—Find the proper air-gap in Table III. Deduct twice the air-gap from the bore to get the armature diameter; jot it down. Multiply the air-gap by 3 to get the maximum allowable slot width.

C.—Find the current per wire from Table I and note it. From Table IV find the estimated size of wire to carry the current; note it. From the left-hand section of Table V find the widest slot (for the wire) that will not exceed 3 times the air-gap; note it. Then from the right-hand section select the deepest slot (for the wire) that does not exceed 6 times the width just found; note it.

D.—From the armature diameter subtract twice the slot depth to get the tooth-root circle; find the circumference of the circle and note it. From this circumference subtract the diameter of the polar bore; divide the remainder by the width of the coil slot to get the number of slots allowable, discarding the fraction in the result if it is less than ⅔, and taking the next larger number if the fraction is ⅔ or over. Note the number of slots.

E.—Multiply the number of slots by the wires per slot to get total wires. Apply formula 2 (for a dynamo) or formula 3 (for a motor) to see if the armature will give the desired result. If not, revise the diameter according to the method described under Preliminary Correction.

F.—After correcting, follow out Instructions B, D and E, checking the new proportions by Rules II, III and IV as you go along.

G.—After obtaining a diameter which gives the desired e.m.f. or speed make sure that the total number of wires × amperes per wire does not exceed the limit prescribed in columns 4 and 5 of Table III.

H.—If the ampere-wires should be too great, make the slots one size shallower and apply Instructions D, E, F and G.

Rules.

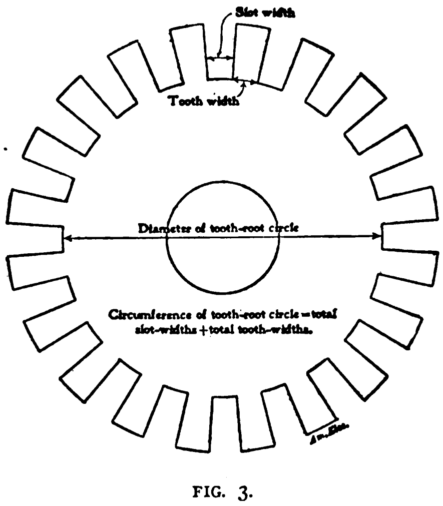
Rule I.—The armature of a 110-volt dynamo of more than 10 kilowatts or a 110-volt motor of more than 12½ horse-power must be lap-wound, with as many paths through the winding as there are poles on the field magnet. All other machines are to have two-path wave-connected armature windings.

Rule II.—The width of an armature coil slot must not exceed three times the length of the air-gap; if possible, it should be kept within twice the air-gap length.

Rule III.—The depth of a coil slot must not exceed six times its width; if possible, it should be kept within four times its width.

Rule IV.—The air-gap length must not be less than the value given in Table III opposite the diameter of polar bore and under the proper number of magnet poles.

Rule V.—The sum of the widths of all the armature teeth, measured at the narrowest part, must be practically equal to the diameter of the polar bore.



Slot width
Tooth width
Diameter of tooth-root circle
Circumference of tooth-root circle = total slot-widths + total tooth-widths.

FIG. 3.

The sides of each slot in the engraving should be parallel instead of radial.

Preliminary Corrections.

Dynamos.—Having obtained a trial polar bore diameter which does not give the desired e.m.f., multiply the desired e.m.f. by the corrective constant corresponding to the trial polar bore and divide the product by the e.m.f. obtainable with the trial bore. The result will be the corrective constant corresponding to the polar bore which will give the desired e.m.f. when Instruction D has been followed without changing the number of wires per slot or the size of the slot.

If retaining the same size of slot violates Rule II, a narrower slot must be substituted and Instructions D and E applied.

If the new polar bore entails an increase in the air-gap sufficient to allow the use of the next wider slot size in Table V, substitute that slot width and apply Instructions D and E.

Motors.—Having obtained a trial polar bore diameter which does not give the desired speed, multiply the speed that it does give by the corrective constant corresponding to the trial bore and divide the product by the desired speed. The result will be the corrective constant corresponding to the polar bore diameter, which will give the desired speed when Instruction D has been followed without changing the number of wires per slot or the size of the slot. If retaining the same size of slot violates Rule II, a narrower slot must be substituted and Instructions D and E applied.

If the new polar bore entails an increase in the air-gap sufficient to allow the use of the next wider slot size in Table V, substitute that slot width and apply Instructions D and E.

sponding bore is between 8⅛ and 8¼ in. Taking the larger diameter, the air-gap (Table III) will be 7-64 in., and the slot width still comes within the limit prescribed by Rule II.

The next step is to see whether or not the number of ampere-wires comes within the limit set by Table III. The armature core diameter is equal to the polar bore minus twice the air-gap, of course, and 8¼ — 7-32 = 8 1-32 in. The tooth-root circle will be 8 1-32 — 2 5-16 = 5 23-32 in. in diameter; its circumference will be 17.966 in. The tooth roots must be 8¼ in., leaving for the slots 9.71 in.; 9.7 ÷ 0.29 = 33.448, so that 33 slots can be used. This means 33 × 24 = 792 wires total, and the current per wire being 10 amperes (Table I), the ampere-wires will be 7920. The maximum allowable number is 9600 (column 4, Table III), so that we are within the limit by a very safe margin.

The next step is to check the speed. By formula 3, it will be

$$\frac{220{,}000}{0.2513 \times 792} = 1105 \text{ r.p.m.}$$

and if this is undesirably high it can be corrected by increasing the diameter of the armature one point and thereby increasing the number of wires and the factors which are contained in the "constant" K.

The correction of the preliminary diameter of a dynamo polar bore is made in a similar manner. After finding roughly the approximate diameter by means of formula 1, ascertain the size and number of slots, and from these the number of wires; then try the results for e.m.f. by formula 2. If the e.m.f. is not what was intended, find the corrective constant of the polar bore thus far determined; multiply it by the desired e.m.f.; divide the product by the e.m.f. that the armature will give, and the result will be the corrective constant of the polar bore that must be used instead of the one first ascertained.

In order to enable a beginner to grasp the method of "laying-out" more easily, the procedure already described is summed up in the accompanying code of instructions. For still further simplifying the method, formula 1 has been substituted for formulas 1-a and 1-b of the preceding article, and Tables II and III have been made to eliminate Table III of that article. Table VI is new this month, and should be consulted as a guide to the proper number of turns per armature coil. The limits in the table are not rigid, but they should not be exceeded when it can be avoided. It should not be forgotten that the speed values in Table III are merely suggested as appropriate for fairly high-speed armatures; the method of design on which these articles are based is not dependent on the speeds in the table.

◆

Simple Polarity Indicator.—A very simple and efficient polarity indicator may be made from white blotting paper saturated with a solution of potassium iodide. When a test is to be made the paper is moistened and the leads pressed down upon it about a half-inch apart. The positive end will turn brown, while the negative will not be affected.

SOME HINTS ON CONDUIT WORK.

BY T. F. M'MACKIN.

The use of conduits or iron pipes is the favorite method of concealing wires for all purposes in newly erected edifices. Although this system has many advantages over the old methods employed, especially those involving the use of mouldings and porcelain cleats, it presents many difficulties not easily overcome. These difficulties are met with chiefly in overhauling old buildings, or in fire-proof construction in warehouses, power houses, etc. In running circuits on the ceilings of a warehouse or storage plant, extra strong beams are often encountered. These run the entire length of the floor and are supported by 12-in. x 12-in wooden pillars placed equal distances apart to increase the holding capacity of the floor. In passing under these beams a saddle bend is required, as shown in Fig. 1. Fig. 2 illustrates a badly-made saddle which is often used; it is of poor workmanship and is dangerous in floors having a low ceiling. Saddle bends on pipes under the floors are easy to make. Wherever the pipe crosses a beam it is pounded with a heavy plank or joist until it conforms to the shape of the beam, using one's feet to steady same during the operation. Saddles required on the ceiling are bent first according to measurement and then installed. The best method is to place a size larger coupling between the jaws of a double-V vise.

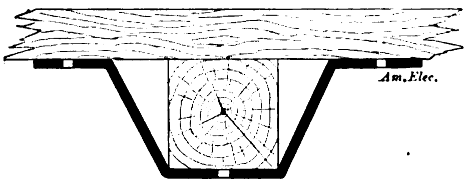


FIG. 1.

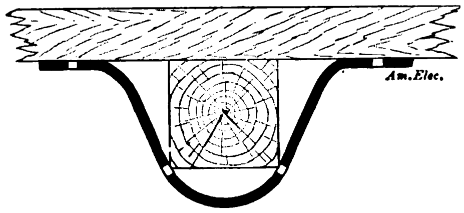

FIG. 2.

The trouble met with in fire-proof buildings lies in the question of hangers or fasteners; there is no woodwork to fasten the pipes to, but a number of wrought-iron I-beams are available. Special wrought-iron hangers can be made, suitable for almost any conditions. This scheme has been applied to several power houses in this city with good results. Fig. 3 shows a sketch of several circuits in ½-in. pipe conduits carried across the ceiling from the switch box to their respective outlets. Each of these circuits, twelve in number, comprises two No. 14 B. & S. wires and the conduits are held by hangers attached to the wrought-iron I-beams. The hanger is made of strap wrought iron ¼ inch thick and 1¼ inch wide and is in two parts, the top and bottom. Each part consists of a bar 10 inches long, having a hole ⅛ inch in diameter at each end and one in the center; ⅛-in. bolts and nuts serve to hold the parts together. The top bar has two extra holes at the center to hold small wrought-iron lugs which grasp the I-beam, as shown in Fig. 3*a*. The top bar is put up first, then the pipe and the bottom bar.

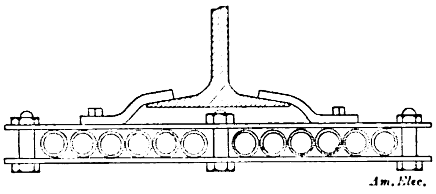

FIG. 3.

Figs. 4 to 12 represent band iron hangers used in the same power house and a scheme for holding a conduit box. The band iron is ⅛ inch thick and 1 inch wide and is serviceable for all small sizes of conduit. In the majority of cases the I-beam is dug out on both sides to admit the lugs of the hanger. In Fig. 4 is shown the hanger most commonly used, consisting of a small piece of band iron 5 inches long. It has a hook bend on each end and is secured in place by hammering both ends over the edge of the I-beam. There are three forms of this hanger, one to accommodate a single pipe irregular in form, one to accommodate three pipes and another to take four pipes. Fig. 5 is a good firm hanger in three parts, the top and bottom and the lugs for holding them. The top and bottom pieces have a ¼-in. hole in each end and lugs have each a hole corresponding to these. One end is made up before installing and the other is made fast to the beam. Two flat-headed bolts connect all three parts together and fasten it in place on the beam. Fig. 6 is the same hanger applied to two beams 1 foot apart. The hanger is made to accommodate ten or twelve ½-in. conduits. The lugs are provided with hook bends on each end and a ¼-in. hole in the center for a flat-headed screw to pass through. The ends are first bent up square and then ham-

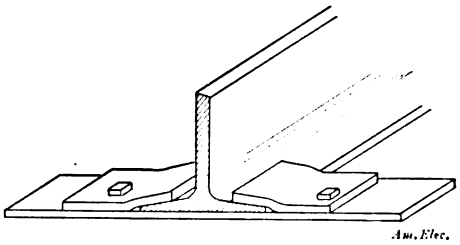

FIG. 3A.

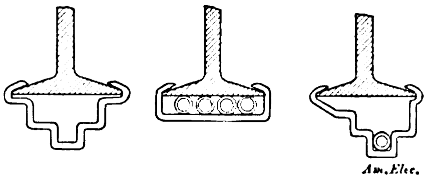

FIG. 4.

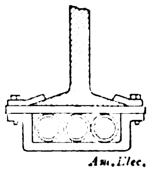

FIG. 5.

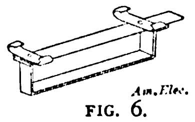

FIG. 6.

mered over the outside edges of the I-beam or girder. The other two parts are fastened to the hanging screws by small nuts on the bottom. Figs. 7 and 8 are clamps or holders used to keep the pipes uniform; these consist merely of two plain wrought-iron bars held together by means of three flat-headed bolts and nuts. Fig. 9 is a channel-iron resting on two I-beams and having a ⅝-in. hole drilled in the center. A ½-in. close nipple and two ½-in. lock nuts, one on top of the channel-iron and one inside the box, hold a conduit box to the channel-iron. Fig. 10 is a hanger of the slip-joint type, the lugs used being the same as those just described. To each C-shaped lug is attached a U-shaped loop; a loose wrought-iron bar, 2 inches wide by ⅛ in thick, laid across these loops, completes the hanger.

FIG. 7.

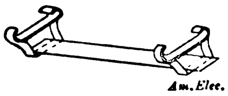

FIG. 10.

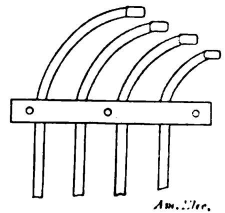

FIG. 8.

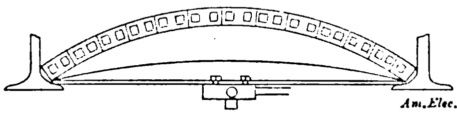

FIG. 9.

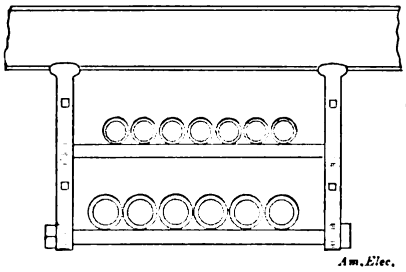

FIG. 11.

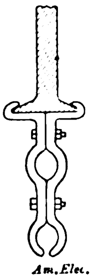

FIG. 12.

Figs. 11 to 16 illustrate hangers of a more unique and substantial nature. Fig. 11 is a double-pipe hanger arranged in such a way as to accommodate two rows of pipes, one underneath the other, and is made of ⅜-in. wrought iron. The upper bar carries ½-in. conduits and the lower 1¼-in. conduits running parallel to each other. The hanger is supported by means of two wrought-iron clamps, one end of which grasps the I-beam while the lower end is made to grasp a 1-in. pipe. For convenience the clamps are made in two parts and held together by short ⅜-in. bolts and nuts, as shown in Fig. 12. The 1-in. pipe which serves as the bottom hanger is provided with thread and lock nuts to prevent it from shifting. Fig. 13 is a hanger that can be used at the crossing or intersection of two beams. The lugs and loops are made from a wrought-iron bar ¼ in. x 1 in. and holding a piece of wrought iron 15 in. long and 4 in. wide. The single loop is attached to one beam and the other two to the beam meeting it at right angles; a wrought-iron bar is laid on the single loop and the main hanger, thus providing for lines running in both directions. Fig. 14 is an arrangement used in places where no beams are to be had in the line of piping, as in the center of an arch. When the distance between beams is not more than 5 feet the plastering can be dug out and a channel-iron inserted extending from one to the other and resting on the flanges, as shown.

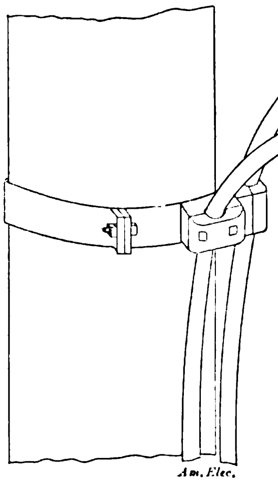

FIG. 15.

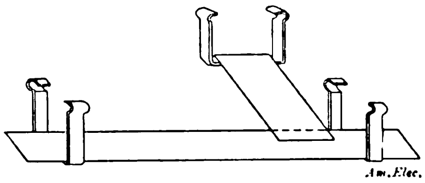

FIG. 13.

Figs. 15 and 16 illustrate hangers for use with heavier pipes and open cables of over a million circular mils, as in six-wire cable. Fig. 15 is a pillar support arranged to hold four or more extra heavy cables. It is of extra heavy wrought iron, ½ inch thick, made to form a complete circle and arranged in two parts for easy adjustment. One-half of the hanger has several ¾-in. holes equidistant from each other. The holes are tapped with a bolt thread and the cast-iron holders bolted on, sunken bolts being used. The two parts of the band are held together around the pillar by ½-in. bolts and nuts. Fig. 16 is an extra heavy U-shaped hanger, applicable to both wrought-iron I-beams and wooden beams. Those designed for I-beams have adjustable lugs and those for wooden beams or joists have ½-in. holes for lag screws. They are used on 3 or 4-in. pipe. The principle of installing piping is a simple one. The hangers should be installed first and then the pipe can be run easily. Never attempt temporary hangers, if they can be avoided, as they are a great handicap.

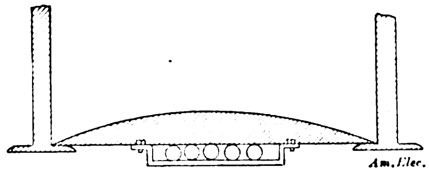

FIG. 14.

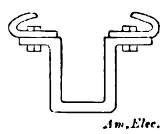

FIG. 16.

PUMPS IN CENTRAL STATIONS.

BY W. T. EDWARDS.

As a factor in the economical operation of a power plant, the pump occupies a position that is second in importance to hardly any other machine. The increase in economy obtainable by the use of the condenser is made possible only by the use of the circulating and vacuum pumps.

The gravity oil systems which are so familiar in up-to-date stations are also a great convenience and source of labor-saving in connection with which the pump again maintains its claim to a prominent position.

In the matter of boiler feeding the pump has a competitor in the injector, many types of which are used for that purpose, but the pump is superior to the injector on account of its better economy and its ability to handle heated water, which the injector cannot do.

Again, the pump is invaluable as a means of protection against fire; many plants are provided with special fire pumps built to meet special requirements of the fire underwriters.

The other uses to which pumps are put, when fluids or semi-fluids are to be moved from one point to another, either at the same or a higher level, are many, but will not be touched upon in this article.

In connection with condensers, the number and kind of pumps necessary will vary with the kind of condenser used; some condensers requiring two pumps and others but one. On the kind of condensers will also depend the size of the pump required to handle the circulating water, since jet condensers require about 30 pounds of water to condense one pound of steam, while in the surface condenser about 50 times the volume of the feed water is used. This large quantity of water may be handled by almost any type of pump of sufficient capacity. Centrifugal pumps are frequently used as circulating pumps, but more often one of the reciprocating type is used with both jet and surface condensers.

In the case of the surface condenser two pumps are necessary, the air pump, also called the wet vacuum pump, which takes care of the water of condensation together with the entrained air; and the circulating water pump, which supplies the water for condensing the steam. These pumps are usually directly connected to the condenser outlets, but this is not imperative; the pumps may be placed at any convenient point and connected to the condenser by pipes, the air or wet vacuum pump being located so that the water of condensation will flow into it by gravity. When jet condensers are used, one pump takes care of both circulating water and water of condensation, together with the entrained air. The circulating water is drawn into the condenser head, where it meets and condenses the exhaust steam from the engine, the whole being drawn through the pump and discharged into a hot well or to waste.

It will be evident from the foregoing that, as the pump with the jet condenser performs the same work as the two pumps with the surface condenser it must be of greater capacity, but it is more economical and is the most common arrangement, unless it be desirable to return the water of condensation to the boilers.

The barometric tube jet condenser requires a type of air pump that may be considered a special air compressing pump, and which is called a "dry vacuum" pump; it is required to receive air at exceedingly low pressure and discharge it against the pressure of the atmosphere. The condensing chamber of the barometric condenser is mounted on a vertical air-tight tube or pipe not less than 34 feet high, the lower end of which is sealed in a hot well or receptacle for holding water. The operation is somewhat as follows: The circulating water is discharged from the circulating pumps into the chamber from one side where it strikes a cone or serrated plate which causes it to break into a spray in the case of a serrated plate being used, and a thin cone-shaped film when the cone is used. Diametrically opposite, the exhaust steam enters, and, passing through this spray is condensed, the whole dropping into the barometic tube, thence into the hot well, passing over the side of the well to waste, or else being pumped back into the boilers. Some of the air that is entrained in the steam passes out through the tail pipe, as the barometric tube is sometimes called, with the circulating water and what remains rises to the top of the condensing chamber and filling it, would soon destroy the vacuum were it not removed. It is the purpose of the dry vacuum pump to remove this air, therefore it is connected to the top of the condensing chamber. Means are provided for the purpose of cooling this air to the lowest possible temperature, the reason for this being that the volume of air is directly proportioned to its absolute temperature,* a pound of air at 80° F. having about 90 per cent of the volume of a pound of air at 140° F.; consequently, the work of a pump is directly proportional to the absolute temperature* of the air.

Whatever the degree of vacuum in the condenser, there must be a still higher degree of vacuum in the pump cylinder in order that this rarefied air will pass into it. And in order to reduce friction, there must be an ample and free passage between the condenser and the pump. After the air enters the pump cylinder it must be compressed to a pressure greater than the atmosphere, so that it will discharge into it; because of this the pump does as much work as it would were it to compress the same weight of air from the atmospheric pressure to a pressure of about 120 lbs. This work requires that the pump be treated like an air compressor; it is water jacketed, and in some cases made in two stages; the clearances are in all cases reduced to the smallest practical amounts and the valves and valve seats are especially designed for these exacting conditions.

The direct acting type of steam pump is usually used for boiler feeding purposes, though the vertical triplex type of power pump is sometimes employed and gives excellent satisfaction. This is usually driven by a motor geared to the pump by a speed-reducing train of gears. Sometimes the pumps are driven by belts from a countershaft. Where boiler feed pumps are electrically driven, alternate means are usually provided to feed the boilers independently of these pumps, as an accident to the supply of power might be a serious matter.

Boiler feed pumps are generally installed in duplicate, each of sufficient capacity for the entire installation of boilers, or at least, for all the boilers that will be in use at one time. This provides for an emergency such as the disabling of one of the pumps. The pumps are sometimes placed side by side at the center of the boiler house and discharge into the middle of a feed water main, which runs along the fronts of the boilers. Another way is to have the pumps placed one at each end of the boiler house, supplying the feed line from either end. Either way is good, but the latter arrangement requires more pipe for both the steam lines and the suction line.

TABLE I.

Vacuum inches mercury.	Air pressure in suction pipe in lbs. per sq. in.	Calculated lift in feet.	Actual lift in feet.

29	0.49	32.71	26.17
30	0.00	33.85	27.07

In the case of fire pumps the board of underwriters requires that they be capable of delivering their rated capacity without hammering and that they be able to run at double the speed of boiler feed pumps or any ordinary water supply pumps. Therefore the fire pump should be stronger, be better constructed, having large steam valve ports and larger suction valve areas than the ordinary pump. It is required that duplex pumps alone be used, and it is recommended that when more than 1000 gallons per minute capacity is required, two pumps be used, estimating that the above amount will suffice for four streams. This allows 250 gallons per minute for a good 1⅛-in. fire stream. These pumps are usually built to withstand the sudden shocks due to turning a full head of steam into a cold pump, which is quite likely to happen when one is under the excitement produced by a fire. Where a fire pump is left standing unused for perhaps months, the rubber valve discs are apt to stick to the seats, and if the lift is very high there may not be pressure enough to open all of them. It is a good plan to work the fire pump at least once in four weeks in order to have everything limbered up. A fire pump should have a vacuum chamber, which may be a vertical piece of pipe of the same diameter as the suction pipe, and about 6 feet long, closed at the upper end. A large air chamber is necessary in order to prevent the hose from vibrating so as to cause holes to be worn through. The pump should have a priming pipe leading from a tank containing water used for no other purpose. A pump rigged with a provision for priming surely and quickly may have the suction pipe without a foot valve. Of course if the pump takes the water under a head the priming outfit is not needed, but openings for priming pipes should be left in the pump shell and fitted with plugs.

In the gravity oil system the oil is stored in tanks elevated above the bearings to be lubricated, flooding the bearings with a pressure varying with the height of the tanks. After passing through the bearings the oil passes through pipes to a system of filters, thence into settling tanks from which it is pumped back into the storage tanks. The pumps used here are almost invariably of the duplex type and are as a rule installed in duplicate. They are piped, with regard to the exhaust pipe, so that the exhaust steam may be passed through a coil in the settling tanks for the purpose of heating up the oil in case it becomes desirable to thin it so that it will flow freely. It is also customary to provide means for circulating cold water through this same coil for the purpose of thickening the oil should it become too light.

Table I shows practical heights to which water can be raised by ordinary pumps at sea level, assuming that the practical lift is 0.8 of the theoretical lift; both the theoretical and practical lifts are given.

That the ordinary pump will not handle hot water without injury to the valves and packing and that no pump will lift hot water are facts well known to everyone who has to do with pumps. Why the hot water injures the valves and packing is not a hard question to answer, but why a pump will not lift hot water is not generally known. The temperature at which water is converted into steam varies with the pressure on the water; at atmospheric pressure the boiling point is 212° F.; under 150 pounds absolute pressure the temperature at which steam is made is 358° F., while under a pressure of 4 pounds absolute, steam is produced at a temperature of 153° F. The reason a pump will not lift hot water is that when the piston moves so as to produce a partial vacuum, the pressure on the hot water is relieved so that it is immediately converted into steam, and the pump draws in nothing but the steam so produced.

When water is heated to a temperature of over 120° it is necessary to arrange the pump or the source of supply so that the water will flow by gravity into the pump. When this arrangement can be secured the successful operation only depends on selecting a suitable pump and valves. A composition of rubber and graphite makes a good valve for hot water and in some cases metal valves are used. The pistons are packed with metal rings or are constructed with what are called "water rings"; these latter consist of shallow grooves turned about the circumference of the piston which fill with water. The reason these grooves are effective is that a sudden enlargement in any cavity through which water is forced induces currents in the cavity that impede, if they do not prevent, a direct passage of water. Because of the difficulty of handling hot water it is customary to place the boiler feed pump so that the feed water is forced from the pump through the feed water heater and thence into the boilers.

---

*Fahrenheit temperature + 460.

Sometimes pumps take their supply under pressure, for instance, where the water used is from the city mains. This pressure varies with local conditions and under no conditions is it uniform. This makes a uniform speed of the pump almost impossible and in the case of boiler feeding a variation of speed in the pump causes the water level in the boiler to vary objectionably. Boiler feed pumps taking their supply under such circumstances should be watched very closely in order to maintain even an approximately uniform water level or steam pressure in the boiler. The reason for the variation in speed of the pump is that the steam pressure on the pump piston is practically uniform and when the opposing pressure due to the column of water which the pump moves is reduced by the pressure in the mains tending to help push this column of water along, the steam pressure exceeds the back pressure too greatly and the pump runs away.

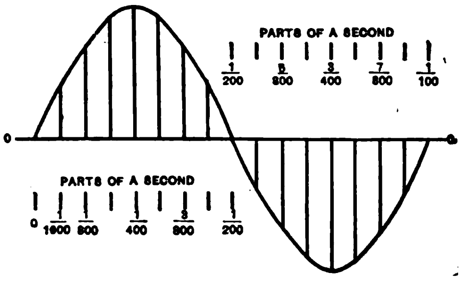

FIG. 1.

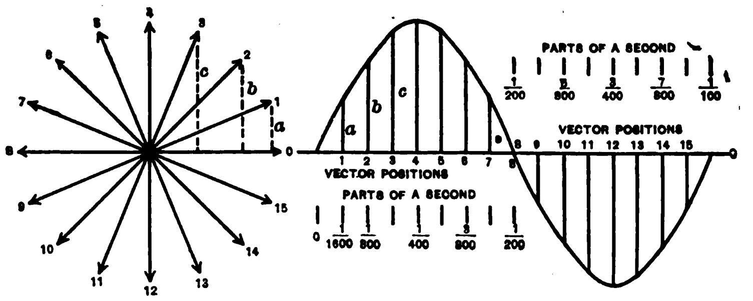

FIG. 2.

There are several methods of controlling the pump speed; one is to place a reducing valve in the suction pipe; another is to throttle the supply by causing the pump to draw the water through the valve. By far the best method is to use a pump governor which maintains the speed practically constant under widely varying pressures.

Lessons in Practical Electricity

ALTERNATING-CURRENT DIAGRAMS.

If a polarized current indicator could be made so free from inertia as to follow the rise and fall of an alternating current like the piston of a steam engine indicator follows the rise and fall of steam pressure, a pencil attached to its needle or pointer and arranged to move to and fro across a moving strip of paper would trace the "current wave" of the generator when the instrument was inserted in series with the circuit; connecting the instrument across the terminals would cause the pencil to trace the "e.m.f. wave" of the machine. For convenience in calculations, these curves are assumed to have the form of a sine curve, as shown by Fig. 1. In practice many machines do give a wave which approaches very closely to a true sine wave.

In Fig. 1 the spaces along the zero or datum lines may be considered intervals of time in fractions of a second. With a frequency of 100 cycles per second, it requires only 1-100 second for a complete cycle, which consists of one positive and one negative impulse, from zero back to zero. Considering the horizontal divisions as intervals of time, the vertical lines would indicate the e.m.f. at instants 1-1600 second apart, as indicated by the figures on the diagram. If there were no such thing as phase difference the curve diagram would fulfil all the requirements, but when currents or electromotive forces, or both, rise from zero to maximum at different intervals of time their mathematical relations cannot be so readily determined from curves as from a system of "vectors."

For convenience, therefore, a cycle, or complete reversal of current or e.m.f. as indicated by Fig. 1, is represented by the rotation of a "vector" about its origin, just as the hand of a clock rotates about the spindle, one revolution representing a cycle. The length of the vector is made to represent the maximum value of the e.m.f. or current, as the case may be, and the distance from the zero line to the outer end of the vector, measured vertically, represents the value of the e.m.f. or current at that part of the cycle indicated by the position of the vector. The latter is usually assumed to rotate left-handedly or counter-clockwise. Fig. 2 shows the relations between the position of the vector and the time intervals of the cycle. Sixteen positions are shown, for simplicity, but it will readily be understood that if the circle described by the vector be divided into 360 parts, as a circle is usually divided, the relation holds throughout, for each degree or fraction of a degree.

If the current in a line lags behind its e.m.f. to such an extent that it does not attain its maximum value until the e.m.f. has fallen back to zero and is about to reverse, as indicated by Fig. 3, it evidently lags one-fourth of a cycle ahead of the reversal of the current. This condition is shown by two vectors having a common origin but being angularly displaced by a fourth of a circle, as shown by Fig. 4. The current is then said to lag 90° (one-fourth of a complete circle), or to be "out of phase" with the e.m.f. by 90°. In comparing phases the zero line is usually omitted, as the object of the diagram is to show merely the phase relations and not the instantaneous values. Consequently it does not matter whether the diagram be drawn as in Fig. 4 or in Fig. 5. The main point is the difference in phase.

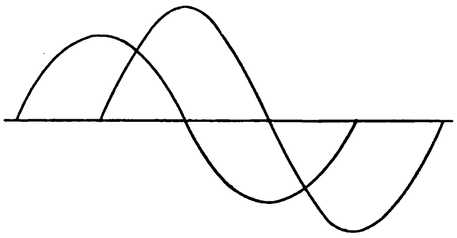

FIG. 3.

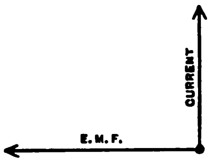

FIG. 4.

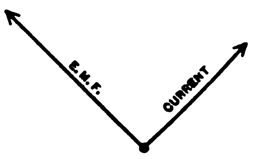

FIG. 5.

Difference of phase between two or more e.m.fs. or currents are also represented by vectors. For example, a two-phase generator supplies two distinct electromotive forces which are of equal value but a quarter of a cycle apart in phase; that is, when one is at zero the other is at maximum. This relation is shown by two vectors of equal length, 90° apart, as in Fig. 6. As in the previous case, it does not matter whether one is horizontal and the other vertical, as in Fig. 6, or whether each forms an angle of 45° with the vertical, as in Fig. 7, or what their position in space is; the important fact is that they are 90° *from each other.*

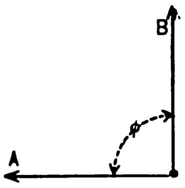

FIG. 6.

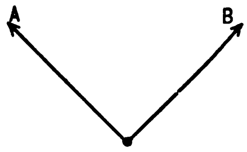

FIG. 7.

The chief convenience obtained by the use of vectors in alternating-current work is in computing the combined effect, or, to express it properly, the resultant, of two or more e.m.fs. or currents which differ in phase. For example, if the two e.m.fs. represented by the vectors A and B, in Figs. 6 and 7, are connected in series, the resultant e.m.f. may be plotted by drawing two lines parallel with the two vectors, as indicated by the dotted lines in Fig. 8, and drawing in a diagonal across the square just formed. The diagonal represents both in length and phase relation the resultant e.m.f. produced by the two original e.m.fs., A and B, combined. If these e.m.fs. are 100 volts each, the resultant will be 141 volts, and it will be ⅛ cycle or 45° ahead of the e.m.f., B, and the same distance *behind* the e.m.f., A. The formula for the resultant of two equal e.m.fs. differing in phase and connected in series manner is:

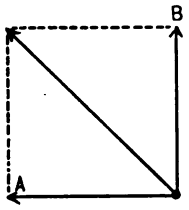

FIG. 7.

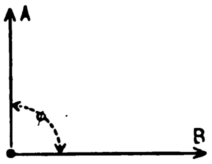

FIG. 9.

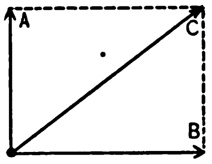

FIG. 10.

$$2 \times A \times \cos (\tfrac{1}{2}\phi),$$

ϕ being the phase angle between the two e.m.fs. This formula applies regardless of the phase difference, but is only applicable to two e.m.fs. of equal value. When two e.m.fs. having different values are combined, as indicated by Figs. 9 and 10, if they are at right angles or 90° apart, the formula for the resultant is:

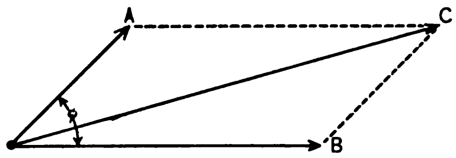

FIG. 11.

$$\sqrt{A^2 + B^2} = C.$$

This is a case frequently met in practice in calculating the e.m.f. necessary to be applied to the terminals of an inductive load, such as an electro-magnet, on an alternating-current circuit. The vector, B, in the diagram represents the e.m.f. required to overcome the resistance of the winding, and the vector, A, represents the e.m.f. required to overcome the reactance or inductive opposition, which is always 90° from the resistance e.m.f. The vector sum of these two is the e.m.f. required at the terminals of the coil. For example, the diagram is plotted to a scale of six volts for A and eight volts for B, and the vector sum of these two, instead of being 14 volts, which is the arithmetical sum, would be 10 volts. The scale of the diagram is one-eighth of an inch per volt, and a scale applied to the vector, C, will show that it is 10/8 long, corresponding exactly to the result of the formula.

When the difference in phase between the two e.m.fs. or currents is other than 90, and the two e.m.fs. or currents have also different values, as indicated in Fig. 11, the calculation is more complicated, the formula being:

$$\sqrt{A^2 + B^2 + 2AB \cos \phi} = C,$$

in which ϕ is the angle between the two vectors, A and B, as indicated in the diagrams. The cosine of any angle may be taken from a table of sines and cosines such as the various engineering handbooks contain.

When three or more e.m.fs. of different phases are to be combined, two of them are first combined, then the result of these two is combined with the third, and so on, until all are combined. The commonest case of this kind is found in a transformer diagram. Fig. 12 is a part of such a diagram relating to the primary winding; the vector, E_r represents the voltage required to overcome the resistance of the primary winding, and which is in phase with the primary current; E_x is the e.m.f. necessary to overcome reactance, which is 90° out of phase with the resistance drop, as already explained, and E_i is the e.m.f. required to overcome the counter e.m.f. of the transformer. The resultant of these three will be the e.m.f. required at the terminals of the transformer, as this must balance all of the internal e.m.fs.

The first operation is to combine E_r and E_x; the resultant of these two is E_z and shown by Fig. 13, and this vector represents not only the strength but also the phase of the resultant e.m.f. Having resolved E_r and E_x into E_z, this must be combined with E_i, as shown in Fig. 14, giving the resultant E, which is the vector sum of E_r, E_x, and E_i.

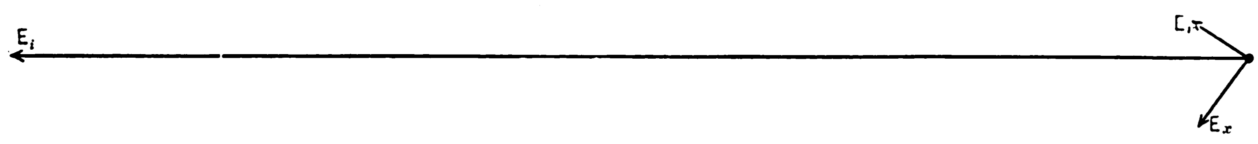

FIG. 12.

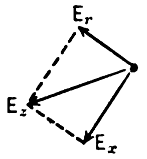

FIG. 13.

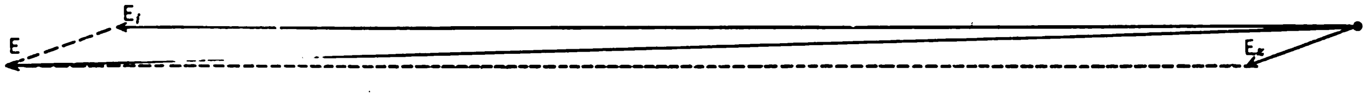

FIG. 14.

The student will find it profitable to make a memorandum of the general rule that vector diagrams and calculations apply to e.m.fs. connected in series and currents combined in parallel; also that all of the currents and e.m.fs. treated in a given diagram or formula must have the same frequency.

Connecting Three-Wire Generators in Parallel.

To the Editor, American Electrician:

Having had to face the problem of connecting three-wire generators in parallel, and finding it not quite so simple as it appeared at the outset, it occurred to me that your readers might like to consider the features that are involved. In the first place, the generators must compound for an increase in load on either side of the three-wire system; in the next place, connecting two or more such generators in parallel necessitates the use of equalizer connections between them, of course. I send herewith the diagram of connections that I used, and would be glad to have readers work out diagrams and submit them for comparison in a future issue of your paper.

Brooklyn, N. Y. Geo. W. Malcolm.

[We withhold Mr. Malcolm's diagram for comparison with those of any readers who may desire to submit their own methods of connecting up.—Editor.]

◆

A Mild Problem in Motor Operation.

To the Editor, American Electrician:

The plant in which I am working includes a number of 500-volt motors, and several of these "blew" their fuses recently under circumstances which may be of interest to your readers. A 10-h.p. motor drives a gang saw, three 7½-h.p. machines drive "rubbing beds" and a 5-h.p. motor drives other machinery. The 10-h.p. machine is fused at 40 amperes, the 7½-h.p. motors at 20 amperes each and the 5-h.p. motor at 15 amperes.

The saws driven by the 10-h.p. motor stuck in the work, stalling the motor and blowing its fuses; the fuses of the 5-h.p. motor and two of the 7½-h.p. machines immediately blew also, but those of the third 7½-h.p. motor did not; the lever of its starting box fell back to the "off" position. I should like to have readers of the American Electrician offer an explanation of the results of the initial trouble with the 10-h.p. motor.

Cleveland, Ohio. Harold Notholf.

Sprung Tubes in Water-Tube Boilers.

To the Editor, American Electrician:

Referring to the letter under the above heading, on page 547 of your October issue, and signed by J. C. Fuller, Poughkeepsie, N. Y., which shows a cut of our Keeler water-tube boiler, we desire to call your attention to the fact that the boilers at the plant in Poughkeepsie are not Keeler boilers, so that the use of this cut is rather misleading as showing our boiler in connection with the troubles mentioned in the article. While we are always willing to have a free advertisement we would prefer to be advertised in some other way.

E. Keeler Company.
Wm. E. Gray, Ass't. Gen'l Mgr.
Williamsport, Pa.

[As the illustration referred to was sent to us by our correspondent, we are, of course, not to blame for the error. Mr. Fuller writes us that he clipped the illustration from an engineering paper and sent it with his letter merely to show the general type of the boilers referred to, but did not expect it to be published. As he did not explain this in his first letter, and we had no means of knowing that the cut did not illustrate the boilers actually in his plant, we naturally supposed the picture was for use in connection with his letter. The boilers in question are, of course, not Keeler boilers, but even if they were we should not consider the reference uncomplimentary to the Keeler Company; tubes in this class of boiler do not spring on account of faulty construction or material as a rule, but because of some abnormal condition of operation. However, we regret the error quite as much as anyone concerned.—Editor.]

Mr. Pool's Problem in Bell Wiring.

To the Editor, American Electrician:

I enclose herewith a solution to Mr. Pool's problem in bell wiring which appeared in the October number. Only one pair of wires is required. These are connected as shown in the sketch to the push button, *c*, in the parlor and at *x* and *y* in the kitchen; putting the door opener, *d*, and the bell, *e*, in series when the button in the parlor is pushed. Since the bell does not have the full potential of the battery across it, the difference in the intensity of sound is easily distinguished and the vibration of the armature on the bell keeps the door opener from sticking.

Brooklyn, N. Y. Paul Watrous.

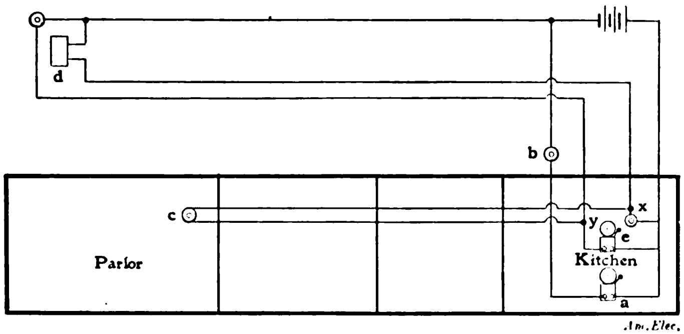

FIG. 1.—MR. WATROUS'S SOLUTION.

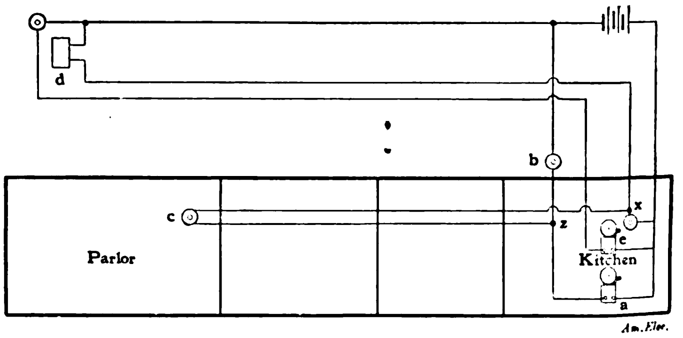

FIG. 2.—MR. M'BRIDE'S SOLUTION.

[Solutions identically the same as that shown by Mr. Watrous in Fig. 1 were received from J. J. Marshall, San Francisco, Cal.; J. Siddall, Kearney, N. J.; H. A. Fiske, Kingston, R. I., and L. M. McBride, Denver, Colo.]

To the Editor, American Electrician:

I enclose herewith a sketch of connections which I believe will meet the requirements of Mr. Pool's problems in bell wiring. One line from the button, *c*, in the parlor, is connected at *x* and the other at *z*, which places the bell, *a*, the push button, *c*, and the door opener, *d*, in series.

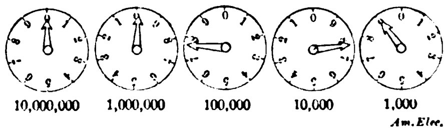
Denver, Colo. Lewis M. McBride.

[Solutions substantially like the above were received from M. H. Williamson, Athens, Ohio; J. Glogan, New York; M. S. Bassett, Birmingham, Mich.; W. J. Southeimer, Cleveland, Ohio; F. E. Du Bois, Troy, N. Y., and J. W. J. Manning, South Boston, Mass. These solutions differ from Mr. Watrous's only in the choice of bell. In Mr. Watrous's solution bell *e* rings, whereas in Mr. McBride's solution bell *a* rings. Numerous solutions were received requiring a three-point switch and three wires, together with an extra battery; but these solutions are inadmissible according to the conditions of Mr. Pool's problem.—Editor.]

Mr. Zimmerman's Tricky Meter Reading.

To the Editor, American Electrician:

I wish to submit the following solution of the meter-reading problem presented by Mr. Zimmerman in this department of the October number:



TRICKY METER READING.

The first pointer (extreme right-hand dial) obviously indicates 900. The next one, having passed 7 and not yet reached 8, indicates 7; this is also true of the third pointer. The pointer of the fourth dial appears to be at 0, but it cannot be quite there because the preceding one has not yet completed its revolution; the fourth pointer, therefore, must be read as at 9. The fifth one is the one involving the "catch." If the meter had recently started from complete zero, all the other pointers being in the positions shown, the fifth pointer would be not quite at 1, the preceding one having not quite reached 0. As it (the fifth hand) is not near 1, it must be considered not quite at 0, so that it still indicates 9. The reading, therefore, is 9,977,900.

New York. John S. R. Bell.

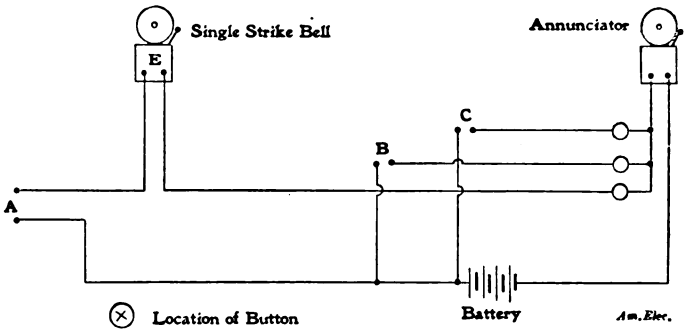
[The foregoing solution is correct. The correct reading has been sent in also by W. M. Aiken, Bennington, Vt.; R. C. Barton, Alameda, Cal.; Abel Beule, Memphis, Tenn.; James B. Dillon, Louisville, Ky.; George W. Graham, Champaign, Ill.; Frank Harris, Sackville, N. B., Can.; B. F. Hessom, Aspinwall, Pa.; Fred. Knowlton, Ashland, Wis.; R. R. McCreary, Kansas City, Mo.; C. H. Pool, New York; Leon C. White, Brattleboro, Vt.; Samuel Wilkinson, Northville, Mich.; M. H. Williamson, Athens, Ohio.—Editor.]

Problem in Bell Connections.

To the Editor, American Electrician:

I enclose herewith a problem which might interest your readers to solve. In a house having a three-point annunciator, a single-stroke bell, *E*, was connected in series with button, *A*. It was desired to connect a button in the basement, so that the single-stroke bell, *E*, could be rung as a vibrator without interfering with the action of the bell when rung from the button, *A*, as a single-stroke bell, and without at the same time causing the annunciator to indicate and the annunciator bell to ring when operated from the push in the basement. Owing to the construction of the house, no wiring can be done except in the basement. The wires from buttons, *A*, *B*, *C*, and from bell, *E*, however, drop to the basement before going to the annunciator, so that no trouble need be experienced in making the necessary connections, etc. I desire to know the most practical and economical method of accomplishing this.

Buffalo, N. Y. J. Remey.



MR. REMEY'S PROBLEM IN CONNECTIONS.

Queries and Answers

IMPORTANT.—No attention will be given to any inquiry which does not give the full name and address of the inquirer.

Where can I find complete instructions for electroplating? J. J. Y.

In Philip's revision of Watt's "Electrodeposition"; price, $4.50.

If an armature coil in a Brush arc-light dynamo were wound in the opposite direction to the proper direction, would it generate the right e.m.f. if the leads were reversed? L. G.

Yes.

Are any of the features or parts of the automobile described in the July (1904) number patented? D. L. R.

No; anyone is at liberty to build the apparatus described in the article immediately following the editorial pages of each issue.

What is the formula for the horse-power developed at the pulley of a three-phase motor? E. E. Q.

Representing the e.m.f. by E, the current per phase by I, the power factor of the motor by p, and its efficiency by e,

$$\frac{E \times I \times p \times e}{430} = \text{horse-power.}$$

If electricity is a form of heat, at what temperature must a generator be to give out current? F. S. L.

Electricity is not a form of heat; the temperature of a dynamo-electric generator has nothing to do with its e.m.f. or current production. A thermo-electric generator gives an e.m.f. as soon as the active parts of its conductors are heated above the temperature of the other parts or cooled below that temperature.

Why are synchronous motors called "synchronous"? (2) Why are they not used for general service, like induction motors? T. J. M.

Because the reversals of the counter e.m.f. of the armature are always of exactly the same frequency as those of the supply current. (2) Because they are much more difficult to start up from standstill, are very sensitive to changes in frequency and (usually) will not carry as great overloads as the induction motor.

What governs the flow of current in an induction motor running at full speed under no load and running under widely varying loads? W. W. L.

The counter e.m.f. of the machine, which varies roughly with the speed; the latter varies when the load varies, being highest at no load and lowest at full normal load. The variation is, however, slight. See Lessons Department, March, April and May, 1901.

What is a "cross-compound" engine, and how does it differ from an ordinary compound engine? E. E. Q.

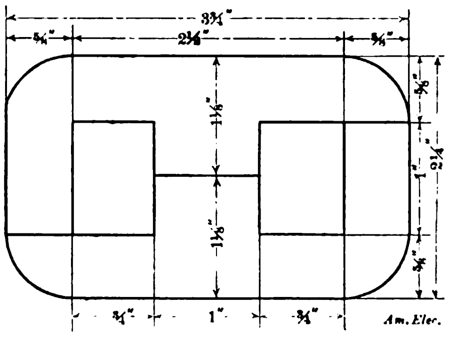
It is a compound engine with the cylinders located side by side and two piston rods connected to two separate cranks on the same shaft. A tandem compound engine has the cylinders located one behind the other, both pistons being mounted on a single rod and therefore delivering power to a single crank. Both of these are "ordinary" compound engines. Any other form is highly special.

What is the difference between the results produced by rectifiers and commutators? S. K. N.

A rectifier changes alternating current into pulsating direct current having either the same number of impulses per second as the number of alternating-current reversals or half that number. A commutator changes alternating current into almost unvarying direct current, the pulsations being negligibly small in amplitude and of a much higher frequency than those of the alternating current.

Please give data for winding the transformer core shown by the accompanying diagram; the primary to take current from a 60-cycle circuit of either 55 or 110 volts and the secondary to give 5 volts. (2) What will be the current capacity of the secondary? W. S. B.

Wind two primary coils (on the center leg) with 13 layers of No. 24 double silk-covered magnet wire, each coil to contain 230 turns; wind the secondary coil with No. 11 double cotton-covered wire, 22 turns total. Connect the primary coils in series for 110 volts and in parallel for 55 volts. The core should be built up to a thickness of 2¼ inches. (2) About 6 amperes.



What is meant by "underload release" in connection with motor starting boxes? (2) Why is it desirable? W. T. K.

The term is not quite correct; "under-voltage release" is more accurate. It is an auxiliary mechanism which releases the lever of the starting box when the circuit voltage falls below a safe working value, allowing the lever to be thrown to the "off" position by a spring. (2) For the purpose of preventing damage to the motor armature should the voltage suddenly be restored while the armature is at rest.

What are the correct applications of the terms "compensator" and "compensated"? (2) If the starting apparatus used with induction motors is a "compensator," why is not such a motor "compensated"? G. L. V.

It is difficult to say within the scope of this department. Both terms are used erroneously in many instances. "To compensate" means to make up for something that is lacking; also, to offset or counterbalance something that is present. Hence, a motor having a winding which counteracts or balances its self-induction is called a "compensated" motor. (2) Because that term is applied to a motor with a compensating winding, and it would produce confusion to apply it here. Moreover, it is rather far-fetched to call an auto-transformer starting box a "compensator."

How can I change the winding of a 50-volt, ⅛-h.p. motor to make it a 100-volt dynamo? The armature contains 12 coils of No. 23 wire, 10 turns each, and the field is wound with No. 21 wire; both wires are English gauge. E. F. B.

Rewind the armature with No. 25 wire, B. & S. gauge, 20 turns per coil; rewind the field with No. 27 wire, B. & S. gauge, to the same depth as the present winding. The machine will then run as a motor at 110 volts, but it will probably not work at all as a dynamo. Machines as small as this usually require more watts in the field winding than the armature is capable of supplying.

How does the speed of a differentially-wound motor vary with the load? (2) If direct current be passed through the armature of a direct-current shunt-wound dynamo, would an e.m.f be induced in the field winding? (3) Can the winding for an alternating-current magnet be deduced from the winding on an existing direct-current magnet of the power desired? (4) How can voltage exist without any current? T. N. S.

If the motor has been properly designed, the differential field winding causes the speed to be absolutely constant regardless of load variation; that is the object of using it. (2) No. (3) No; the calculation of magnet windings for use on alternating-current circuits involves inductance and other factors which are not encountered in direct-current work. (4) You probably have in mind *drop* in voltage; the e.m.f. or voltage must be established first in order that any current may flow; current without voltage is the impossibility, not voltage without current. Any separately-excited dynamo will generate its full voltage without a particle of current flowing in the armature; the ordinary magneto generates its full voltage without any current whatever in any of its parts.

Is it practical to use rubber-covered wires for a 10,000-volt, two-phase line 13 miles long? (2) How can the proper size of wire be determined for a four-wire, two-phase circuit? (3) Is it customary to install a separate transformer in each phase of a two-phase or three-phase circuit at points where transformation is required? G. S. D.

It is unnecessary; bare copper wire on suitable insulators is good enough. (2) Approximate the size by means of the direct-current formula

$$\frac{22 \times I \times D}{V} = d^2$$

in which I = amperes per wire; D = distance in feet; V = drop in volts, and d^2 = circular mils of wire cross-section. Assume one size larger wire and find out what the drop will actually be by means of the formula

$$V = \sqrt{(E\,p + I\,R\,)^2 + (E\,q + I\,X)^2} - E$$

in which E = voltage at delivery end; I = current per wire; R = resistance of the line; X = reactance of the line; p = power factor of the load; q = inductance factor of the load (sine of that angle of which p is the cosine). Most of the calculations may be avoided by using the tables in the article beginning on page 421 of the August, 1903, number of the AMERICAN ELECTRICIAN. (3) Yes in this country, thus far. There is a tendency to change to the European practice of using a single two-phase or three-phase transformer.

WESTINGHOUSE GAS ENGINES FOR ELECTRIC LIGHT AND POWER.

A distinctive development of recent engineering practice is the high power internal combustion engine suitable for direct connection to electric generators for lighting, power, railway, industrial, or other purposes. Constituting the only exhibit of considerable size at the Exposition, the Westinghouse gas engines operating in the joint Westinghouse exhibit in Machinery Hall are of much interest. Two types of gas engines are on exhibit, the vertical single-acting and the horizontal double-acting. Both are multicylinder machines, the former having three cylinders with cranks 120 degrees apart, and the latter two cylinders arranged in tandem with a single crank.

As the double-acting engine is of somewhat more recent introduction than the longer established single-acting type, a brief description of its most important features may be of interest. The general data regarding the unit are as follows:

Cylinders, 14½ ins. x 22ins.

Diameter of shaft, 9¾ ins. maximum; in bearings, 7½ ins.

Fly wheel diameter, 8 ft. 9 ins.

Ratio of crank to connecting rod, 1 to 5.45.

Rated capacity, 200 brake horsepower.

Length of unit over all, 27 ft. 4½ in., including fly wheel.

Width over all, 7 ft., engine, 13.3 ft., unit.

Height over all, 8 ft. 2 ins., including fly wheel.

The forward part of the engine—the frame—comprises the housing for the crosshead guide, two main bearings and a bed plate; the two cylinders and all the valve mechanism is supported by a bed plate extension bolted to the bed of the engine frame, both of which are grouted with concrete to the foundation. Cast iron exhaust pipes convey the burnt gases through the floor to a 6-inch exhaust main leading to the atmosphere. Cooling water inlet and return pipes and gas and air supply pipes rise through the floor, thus removing complex and unsightly piping as far as possible from the engine room floor.

A feature of the cylinder construction is that the cylinder, combustion chamber, ignition and exhaust parts, together with the water jackets for the respective parts, are made in one casting. In order to reduce the strains in the metal of the jackets while cooling, the jacket wall is split around the periphery, the opening being closed by a steel tension band and a strip of rubber packing. Suitable hand holes are provided at various points in the water jackets for examining the interior and to remove sediment which might be precipitated in case very dirty water should be used in the jackets.

The combustion chamber is approximately circular in horizontal section and is closed by the admission valve above and the exhaust valve below. Both valves are of the single-beat poppet or mushroom type and seat vertically along the same axis, but in opposite directions, the admission valve opening downward and the exhaust upward. The admission valve is mounted in a separate bonnet which, together with the valve, may be readily removed without dismantling any parts of the engine other than the tappet lever through which the cam motion is imparted to the valve. Both admission and exhaust valves are of steel and are held to their seats by spiral springs. The exhaust valve is water cooled. It is bored hollow throughout its length, and this canal conveys cooling water to the head of the valve; the water returns in the opposite direction through an inner concentric tube, finally emerging at the lower end. By spraying a small part of the jacket water into the exhaust pipes, the temperature of the pipe may be kept at a comfortable point through the absorption of the latent heat of evaporation of the water used.

Both pistons and the piston rod are water cooled, as well as other parts subjected to internal heat. Means for introducing the cooling water is secured by a telescopic pipe connection bolted to the inside of the crosshead guide. The inner tube of this telescopic joint is attached to the crosshead at such a point as to convey the cooling water to the end of the piston rod bore, whence it proceeds in succession through the two pistons, emerging through a bronze tail rod extending through the rear cylinder head. Each piston is a one-piece casting, cored hollow to accommodate the circulating water, and packed by cast iron packing rings set out with flat steel springs. In order to convey the water in and out of the piston, deflecting plugs are inserted at the proper points in the rod bore. A cast iron jacket surrounds the tail rod and receives the water emerging from it, whence it is drained away.

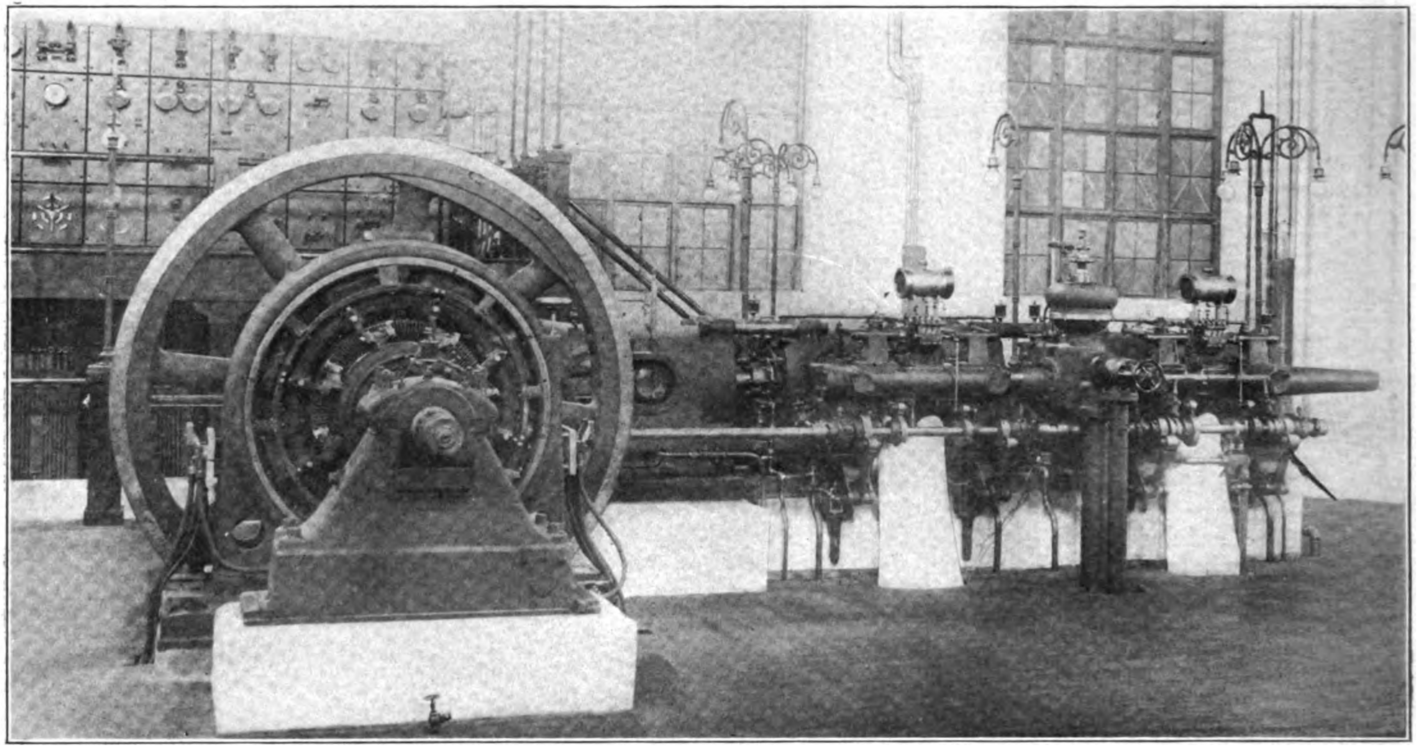


FIG. I.—WESTINGHOUSE HORIZONTAL DOUBLE-ACTING GAS ENGINE.

The many difficulties arising in providing a suitable packing gland for the cylinder heads have been overcome by means of a simple metallic packing similar in some respects to that used on high-pressure steam engines.

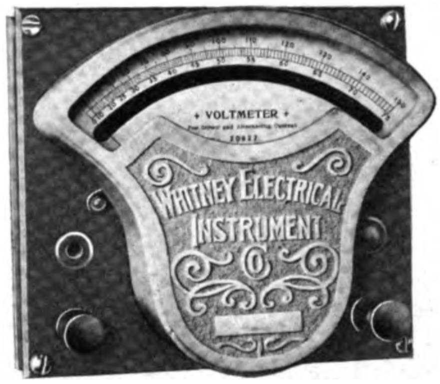
The one lay shaft paralleling the cylinders operates, through cams, all of the valve movements of the engine. Independent cams are provided for inlet valves, exhaust valves and igniters, so that the action of each valve may be timed in order to secure the best results. The main cams are all of cast iron with working surfaces chilled and ground.

The other features of the engine have been described very fully in this and other journals, so that it is unnecessary to consider them here.

New Apparatus and Appliances

NEW HOT-WIRE MEASURING INSTRUMENTS.

The Whitney Electrical Instrument Company has brought out a line of voltmeters and ammeters of the hot-wire type, on which this concern has been working for a long time past. Fig. 2 herewith is a diagrammatic illustration of the underlying principle. A wire, *a-b*, of high resistance, low temperature coefficient and non-oxidizable metal, is secured at one end to a plate, *c*, passed around a pulley, *d*, secured to a shaft, *e*, and its free end brought back again and mechanically though not electrically attached to the plate, *c*. Plate *c* is kept under stress by the spring, *f*, which constantly tends to pull it in a direction at right angles with the axis of the shaft, *e*, and is so guided that it can be moved in that direction only. To the shaft, *e*, is likewise secured an arm, *g*, bifurcated at one end and counterweighted at the other. Between the extremities of the bifurcated ends of the arm, *g*, is another shaft, *h*, on which there is a small pulley and to which is attached the needle, *i*, that gives the desired indications; a fine silk fibre is attached at one end to one of the arms of *g*, then passes around the pulley and the shaft, *h*, and has its other extremity secured to the other arm. The arms are springy and serve to keep the silk fibre taut. The current to be measured flows through the wire, *a*, only, entering and leaving as indicated by the arrows. Evidently, when *a* is heated by the passage of current, it expands, which, as *a* and *b* were originally under the same tension, makes *a*'s tension relatively less than that of *b*, and equilibrium can be restored only when the pulley, *d*, rotates sufficiently to again equalize the strain. The rotation of *d*, of course, carries *g* with it, and *g* in moving causes the silk fibre to rotate the shaft, which carries the needle. If the temperature of the air surrounding the instrument changes, *a* and *b* are affected alike and their resulting equal expansion simply results in a movement of the plate, *c*, back or forth in its path without any tendency to rotate the pulley. The advantages of the above construction are many. The zero adjustment used in this new line of apparatus is also novel. The conventional method of adjusting zero errors in hot-wire apparatus consists in varying the stress on the active wire by moving one of the abutments to which the wire is attached, a procedure which the manufacturer claims is objectionable in that the wire is a member which should be tampered with as little as possible. In these instruments the entire moving system is mounted on a single base plate that is free to rotate over a small angle around a heavy shaft secured to it immediately below and in line with shaft *h*, around which the needle swings. By means of a lever secured to this base plate and projecting slightly beyond the cap that covers the mechanism, the position of the needle relative to the scale may be altered at will without interfering with the wire in any way. While already nearly dead beat in their action, an auxiliary damping device, not shown, is employed. This consists of an aluminum disc secured to the shaft to which the needle is attached and swinging between the jaws of a small permanent magnet. The instruments are made in both portable and switchboard patterns of any range from three volts upward and two hundred milli-amperes upward. The ammeters are all worked on shunts which are contained inside of the instrument case in the small sizes and are separate in the large ones. An idea of the sensitiveness can be obtained from the manufacturer's statement that the ammeters work on shunts giving a drop of but two hundred milli-volts. An illustration of a portable voltmeter of this class is given in Fig. 1. Machado & Roller, New York City, are the general sales agents for the Whitney Company.



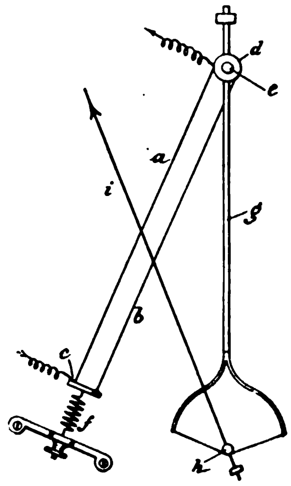


FIG. 1.—HOT-WIRE PORTABLE VOLTMETER, AND DIAGRAM OF CONNECTIONS.—FIG. 2.

HIGH-PRESSURE PACKING RINGS.

The packing ring shown by Fig. 3 herewith is made by the New Jersey Asbestos Company, of Camden, N. J., and is intended for high-pressure work. The asbestos material is molded to shape in steel dies under hydraulic pressure which the manufacturer claims results in a solid packing which at the same time retains great flexibility. The solidity of the rings prevents their being blown out of a stuffing box, and it is stated their application requires but a few minutes. The usual claims as to life and steam-tight qualities are made.

FIG. 3.—HIGH-PRESSURE PACKING RING.

COMBINED SWITCH AND CUT-OUT.

The combined switch and cut-out made by the Hart & Hegeman Manufacturing Company, of Hartford, Conn., consists of a standard 10-ampere, double-pole switch mounted on a porcelain base in connection with two cartridge fuses, all enclosed under one cover, the terminal clips being outside. When arranged for three-wire service, the porcelain base is notched as shown, so that two of these switches can be combined for use on this service. A separate porcelain block, not shown, is furnished for the purpose of protecting the branch conductors from the surface to which the switch is attached.

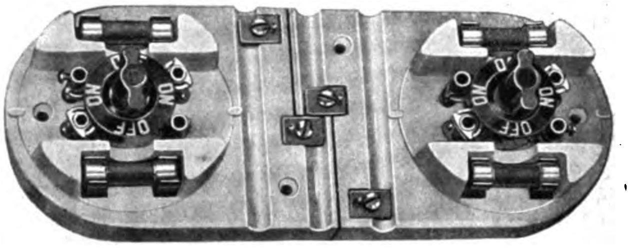

FIG. 4.—COMBINED SWITCH AND CUT-OUT.

"G. I." FLUSH PLUG AND RECEPTACLES.

The receptacle and plug illustrated herewith are said to have new and distinctive features which recommend them as strictly high-grade and efficient in design and workmanship. The body of the plug as well as the receptacle is made of porcelain. The receptacle has a side projection which engages a notch in the plug and thus renders the insertion of the latter particularly easy. Both pieces are liberally proportioned and strong, to withstand severe usage. The face plate is entirely flush when the plug is in or out of the receptacle, all of the joints being close and tight fitting. The small doors have a spring attachment which holds them either open or closed under tension. All

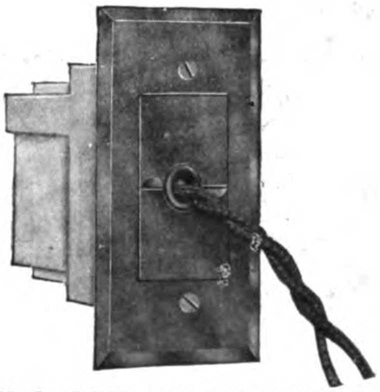

FIG. 5.—FLUSH PLUG AND RECEPTACLE.

parts have been, it is said, very carefully designed, the contact parts are flexible, and the wire inlets and binding posts placed so that the wire connections can be easily made. Unless otherwise ordered, face plates are furnished in polished brass. The size of face plate is 4¼ inches by 2½ inches. The plug and receptacle are made by the General Incandescent Arc Light Company, New York City.

MARSHALL PULL SOCKET.

The Marshall Electric Manufacturing Company, of Boston, Mass., has brought out the socket operated by bead chain pendant shown by Fig. 6. The socket is of standard size, being built upon the standard one-piece porcelain button. The cap is exactly like the cap of an ordinary socket and the shell is only varied from the standard by having a little bell attached to one side in the place of the slot for the key. The metal case is entirely lined with Elastoid fibre, all other insulations being entirely mica and porcelain. The chain pull is radial, which gives a workmanlike appearance to the socket, and there is no grating sensation of the chain rubbing through the bell, the chain being insulated from the mechanism by a short piece of woven linen Tuna line.

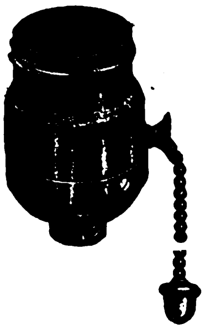

FIG. 6.—MARSHALL PULL SOCKET.

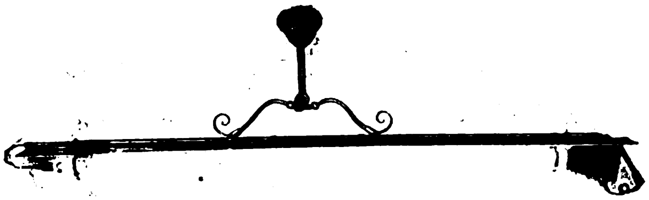

FIG. 8.—HORIZONTAL TYPE H-7 COOPER HEWITT LAMP.

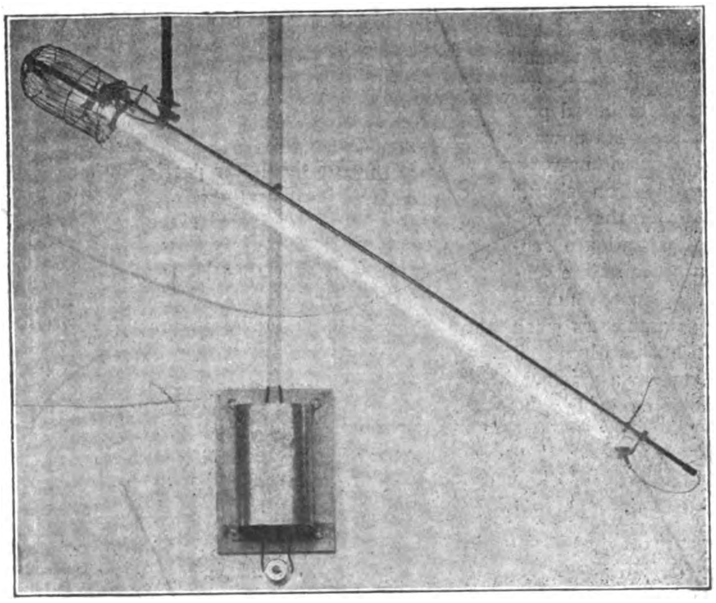

FIG. 7.—INCLINED TYPE V-5 COOPER HEWITT LAMP.

The sockets can be wired just as quickly as ordinary key sockets, the wire terminals being exactly like the standard sockets. The chain can also be detached without removing the shell.

COOPER HEWITT MERCURY VAPOR LAMP.

The mercury vapor lamp invented by Peter Cooper Hewitt and manufactured by the Cooper Hewitt Electric Company, of New York City, is shown by Figs. 7 and 8 herewith. The lamp consists of a glass tube containing a small quantity of mercury. To prevent the escape of the mercury vapor which fills the tube, it is sealed at both ends, after being exhausted to a high degree on a vacuum pump. Metal sealing-in wires convey the current to the electrodes, one or both of which are of mercury. The lamp is started by tilting the tube so that the mercury flows from one electrode to the other in a small stream. This stream momentarily connects the two electrodes, and as the stream breaks the vapor conducts the current and becomes luminous. The lamp is claimed to be the most efficient source of artificial light known. In actual service it is said to have at least double the efficiency of the arc lamp and from six to seven times the efficiency of the incandescent lamp. The color of the light, due to the absence of red rays, has a bluish-green tinge, which causes a modification of color values. Black and white are not affected, but blue and green are, of course, intensified; yellow has a greenish tint and red appears dark purple or black. Despite this characteristic the light is said to be more restful to the eye than any other form of illuminant. The length of the lamp varies with the voltage, lamps for general illumination being from 18 to 45 in. long. Light is diffused from every portion of the tube and the great extent of the luminous surface prevents the formation of sharply defined lights and shadows. The lamp is noiseless in operation and runs with absolute steadiness. The average life of the lamp is about 1000 hours, and lamps used for 2000 hours are said to show but a slight decrease in candle-power. The heat given off by the lamp is less than that given off by any other form of illuminant of the same candle-power. The lamps are made only for direct current at present, although an alternating-current lamp is being perfected. They are constructed to be operated singly on commercial lighting circuits of 50 to 150 volts. On higher voltages nearly all of the standard lamps can be run in series. All of the types are intended to be run at from 3 to 3.5 amperes. The lamps will not operate successfully where the variations in voltage are more than 8 per cent. The mercury vapor lamp can be used for general illumination and in fact any place where the incandescent and arc lamp are applicatory. For uses where actinic rays are required, as in all kinds of photographic processes, it excells all other forms of artificial light. When ordering, the actual average voltage of the supply is required, as well as the maximum and minimum variations.

P. Sorensen, of Brooklyn, N. Y., has brought out the ceiling switch shown herewith, which is unique on account of the ease with which it operates. The switch rod of the usual snap switch is extended through the back of the switch case, as shown, and a rachet and pawl affixed to the end. A cord is attached to the pawl lever and extends low enough to be within easy reach from the floor. The pawl lever is under the action of a spring, which always returns it to its normal position. One pull on the cord closes the switch and the next pull opens it. The device is merely an adaptation of the snap switch for ceiling purposes, the lever performing the operation which in the ordinary switch would be performed by the fingers.

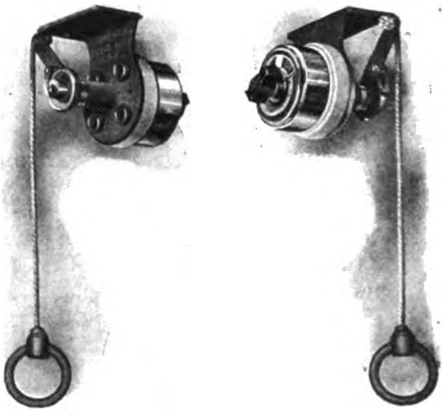

FIG. 9.—SORENSEN CEILING SWITCH.
NEW CEILING SWITCH.

AN IMPORTANT INDUSTRIAL DEVELOPMENT.

The National Electric Company, of Milwaukee, has entered into arrangement with Robert Lundell and Robert T. Lozier, by which the National Company will manufacture and market the new motors and generators, and systems of operation and control that are covered by the latest inventions of Robert Lundell; the commercial direction of the undertaking being placed in the hands of Mr. Lozier, who will also act as general manager of the electrical sales department of the National Company. Under this arrangement Mr. Lundell assumes the direct supervision of the engineering involved under the license that he grants the National Company covering all of Mr. Lundell's inventions not already under license to other companies, and all inventions that he may hereafter make during the life of this license.

These inventions of Mr. Lundell are of particular interest in that they cover important developments in direct-current apparatus. Some of the patents are for a new type of motor and dynamo frame construction, as well as a new method of commutation, by which a material gain is obtained in the space occupied by the apparatus, its efficiency and the flexibility of its speed control and regulation. This form of construction represents an important departure in standard motors of fixed speed, and is regarded as particularly advantageous in variable-speed motors for direct application to machinery, both from the point of construction and that of flexibility of control.

As to the commercial significance of this new arrangement, it is a field with which Mr. Lozier has been associated from the earliest commercial development of the electric motor, he having been in the testing department of the Sprague factory when it was started in West Thirtieth Street in 1887. He has since followed the development of the business in all its phases. Mr. Lozier will be aided in directing the work of his department by his long experience in the electrical field, beginning with Edison early in 1883 and running down through the engineering and commercial branches of the business for 13 years with the General Electric Company and eight years with the Bullock Electric Manufacturing Company.

Mr. Samuel Watkins is the president of the National Electric Company. He organized it, and under his able direction the company has reached its present prominence. The first vice-president and general manager of the company, Mr. Frank C. Randall, is widely known throughout the electric street railway field and the air brake sales will continue as in the past, under his direct charge. Mr. Bernard T. Becker, who represents the interests of those financially back of the company, and who is himself a large stockholder and a director in the company, will act in an executive capacity in connection with the operation of the company. Of the operative force, Mr. R. P. Tell is the secretary and treasurer. Mr. J. H. Denton, well known to all those who come in contact with the air brake business, is general superintendent.

NEW BOOKS.

Photographic Lenses. A Simple Treatise. By Conrod Beck and Herbert Andrews. Second Edition. London: R. & J. Beck, Ltd., and Percy Lund, Humphries & Co., Ltd. Cloth, 320 pages, 7½ inches by 5 inches; 44 half-tone plates, numerous wood-cut illustrations and diagrams. Price, 75 cents.

This book is intended, primarily, as an argument for the Beck lenses, but contains so much information about lenses in general that it is valuable to any one who is interested in lenses or photography. The authors are anxious to improve the work, so offer three prizes for the improvement of the next edition; one for the correction of "grammar, style or matter," one for new matter and one for the best photograph taken with the Beck or Beck-Steinheil lenses. The half-tone plates are of a superior character, and make the volume attractive; the reading matter is interesting, the descriptions being lucid and concise.

Methods of Chemical Analysis and Foundry Chemistry. Second Edition. By Frank L. Crobaugh, M. S. Cleveland, Ohio, 1904. Cloth; 109 pages, 4½ inches by 6¾ inches. Price, $2.00.

This is evidently the work of a thoroughly practical iron chemist; practical, not in the sense that he is deficient in theory, as the word is sometimes incorrectly used, but in the sense that he is the master of his subject and writes things that he has done himself many times. To be sure, it is somewhat academic to give constants to ten places of significant figures, as the author does in one case, or even to eight or nine places, as he does in other cases; especially as the constants depend on such uncertain quantities as atomic weights. However, one can forgive a bit of pedantry, for the book is full of common sense; for example, the author uses a method of tabulation and inspection, in calculating the ingredients of a mixture, in preference to the method of alligation alternate. Alligations alternate is the academic method, but it is not graphic, like the tabular method, and in arranging mixtures of substances containing many constituents it becomes very complicated; besides, it is usually impossible to arrange a mixture with mathematical accuracy: all that is possible or necessary, to secure results, is an approximation within given limits. It is to be hoped that foundrymen will study the foundry chemistry, for the old rule-of-thumb foundry method, or lack of method, is an anachronism in the twentieth century.

SOME EXHIBITS AT THE ST. LOUIS EXPOSITION.

WESTON ELECTRICAL INSTRUMENT COMPANY, Waverly Park, N. J., has a neat booth near the National Bureau of Standards, facing the southeast entrance of the building. This is handsomely fitted up and in it are displayed a large number of the celebrated instruments manufactured by the company. Some of the newer types recently brought out are also shown.

KELLOGG SWITCHBOARD AND SUPPLY COMPANY, Chicago, Ill., has a working exhibit consisting of a 3500-subscriber exchange which is giving actual service to the officers of the Exposition and the exhibitors. The switchboard panels are identical with those recently installed in the Cleveland exchange. The company is also exhibiting its new harmonic system for four-party lines. On a table beside the generator for the working exchange are two harmonic ringers and a rack upon which are mounted several sets of apparatus adjusted to the different calling frequencies. In addition to the working switchboard, two other panels of the Cleveland type are shown, by which the construction and arrangement of all of the parts are rendered apparent. The company has also a fine display of its telephone appliances, and in an adjoining section two machines are in operation covering wire with silk.

THE HARRISON SAFETY BOILER WORKS, Philadelphia, Pa., has an exhibit at the Louisiana Purchase Exposition consisting of five Cochrane feed-water heaters and purifiers, two Sorge-Cochrane systems and fifteen Cochrane steam separators and Cochrane oil separators. These appliances are located in various parts of the Gas, Steam and Fuel Building and the Palace of Machinery, in connection with working exhibits. There are 8000 horse-power of Cochrane feed-water heaters and purifiers, in two units of 4000 horse-power each, in the exhibit of the Westinghouse-Church-Kerr Company in the east end of the Gas, Steam and Fuel Building. In the same exhibit there is located a 6-in. Cochrane vertical steam separator. In the intramural power plant there is a 1750-h.p. Sorge-Cochrane system. The Sorge-Cochrane system, which is used in connection with the Cochrane heater, provides for the chemical treatment of the feed-water in addition to the purification obtained by thermal means in the heater, so that by a simple chemical reaction the sulphates present in the water may be precipitated in the heater. Provision is also made by means of a filter bed for holding back these precipitates and other solid impurities, thus preventing them from reaching the boilers. In the intramural power plant there are also three Cochrane receiver separators, and one 40-in. Cochrane vacuum oil separator. The 14-in. Cochrane receiver separator shown in the accompanying illustration protects the pump in the Underwriter fire pump station. A 1250-h.p. Cochrane heater heats and purifies the water for the boilers in the Philippine Government Board exhibit. In connection with the exhibits of the P. DeC. Ball, Kroeschell Bros. and the Carbondale Machine Company, there are two Cochrane heaters and six Cochrane separators, ranging in size from 2-in. to 7-in. The exhibitors' power plant also includes one 1200-h.p. Sorge-Cochrane system and three 6-in. Cochrane receiver separators.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, Pa., has an exhibit in Section 20 of the Palace of Electricity. This is claimed to be the largest, most comprehensive and instructive exhibit ever made of storage batteries and apparatus used in connection with battery installations. One of the prominent features is a large map of the United States, about 30 by 45 feet, on which is indicated, by means of colored jewels, the location and character of the various installations of the chloride accumulator. The exhibit includes a model battery house, in which is installed a model regulating railway battery operating on a variable load. Five standard marble switchboard panels are shown, including the panels for controlling the model railway battery. The other panels are an Edison central station three-wire panel, the panels for regulating combined lighting and power loads, the railway feeder panels and panels for regulating railway power house loads. Two motor-driven boosters are also shown, the smallest being used in connection with the model battery, and the larger a standard 100-kw. railway regulating booster. Among the types of chloride accumulators are three H-61 cells, with a discharge capacity of 4800 amperes for one hour, six cells type G-77, capacity 3000 amperes for one hour, and types G-17 and F-17, all of these being in standard lead-lined wooden tanks. The smaller cells shown are types "F," "E" and "D," in glass jars, and types "E" and "D," in rubber jars, for train lighting and yacht lighting. There is also shown a very complete set of Exide cells for automobiles, and Exide sparking sets for gas and gasoline engine ignition. The Exide exhibit includes a large easel, showing in detail the various component parts of the Exide battery. At one end of the space is a group of three large end cell switches, operating from the Edison three-wire panel. The model battery, with its booster and switchboard. forms a very interesting working exhibit. The battery is of type E-15, in lead-lined wooden tanks, and is mounted on white enamel brick tiers. The battery is in every particular an exact model in miniature of the larger railway installations. It is insulated from the brick tiers by means of standard double insulation, consisting of vitrified bricks, then glass insulators, then prepared wood stringers and another set of glass insulators. On the switchboard controlling the model battery are the necesary switches and automatic circuit breakers with their interlocking devices, a recording voltmeter and other instruments, consisting of voltmeter, battery ammeter, the generator ammeter and the total load ammeter. The conditions under which the model battery operates are exactly similar to street railway conditions. With the battery regulating, a load of 300 amperes is thrown on the system, causing a drop in the lighting or generator circuit of less than one volt in 110, and a rise in current in the line, or generator circuits, of less than 7½ per cent of the total load. The action of the battery is automatically controlled by the small booster and its carbon regulator.

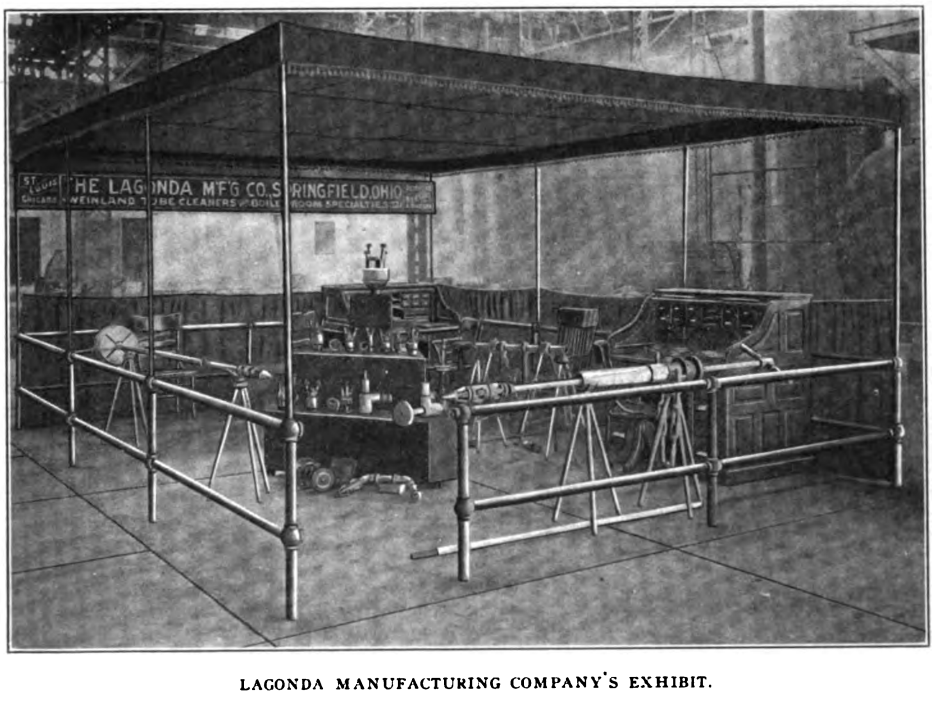
SWITCHBOARD

KELLOGG SWITCHBOARD AND SUPPLY COMPANY'S EXHIBIT.

THE LAGONDA MANUFACTURING COMPANY, of Springfield, Ohio, has an exhibit in the Steam, Gas and Fuel Building, where, in the midst of a lot of boilers of different makes, which furnish steam for the Exposition, it displays its line of cleaners. A view of the exhibit is shown herewith. At the right is shown the mechanical cleaner, while running along the railing on the left is shown the motor-driven cleaner. Water-power cleaners of different sizes are shown on the pyramid in the center, which is surmounted by an 8-in. turbine cleaner. The company claims to have made the largest turbine-driven cleaner ever built, this being 12 in. in diameter. Tube cutters and reseating machines are also shown, as well as power cleaners for boilers of the bent-tube type. This machine is shown in the back part of the photograph, between the pyramid and the desk. The cleaning head and flexible shaft are shown on the floor in front of the pyramid, and just to the left of this is shown a reseating machine, as arranged to be driven by an electric motor. The cleaners have been adopted by the managers of the different boilers, as well as by the Exposition managers for cleaning the boilers in the Steam, Gas and Fuel Building, so that anyone interested can see the machines in operation, as well as the damper regulator made by the company.



LAGONDA MANUFACTURING COMPANY'S EXHIBIT.

THE AMERICAN CONDUIT COMPANY, of Chicago, has an attractive and interesting exhibit in the court of the Palace of Electricity. The exhibit is worthy of the attention of anyone interested in underground electrical construction. It demonstrates the high class of underground construction obtained by the use of bituminized fibre conduit. A portion of the underground system with the street, the earth and the concrete filling removed to expose the ducts themselves is also shown. This portion brings out one of the advantages of the long lengths, namely, the few joints in the system and also shows the alignment secured and the sealed joints, a feature invented and introduced by this company.

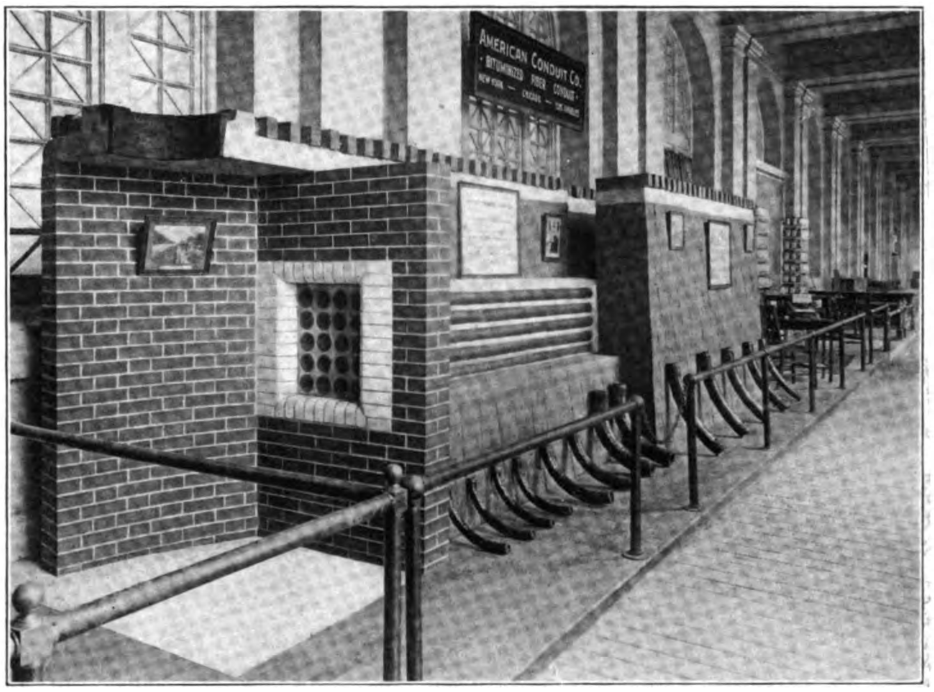


EXHIBIT OF THE AMERICAN CONDUIT COMPANY.

Another portion of the exhibit shows the open trench with the various layers of ducts as they appear in the course of actual progress of the construction work. There are, in addition to the above, some bends of various radii and diameter and some lengths of conduit. Also some interesting photographs showing construction work in various cities where bituminized fibre conduit has been used. An attractively furnished office is provided for the convenience and comfort of those who are directly or indirectly interested in electrical conduits.

THE D. & W. FUSE COMPANY, of Providence, R. I., exhibits two boards in the Western Electric Company's exhibit, showing this company's different forms of cut-out boxes. Board No. 1 displays a complete line of boxes designed to operate satisfactorily on circuits ranging from 250 to 6000 volts, and comprising the following types: Transformer cut-outs, service switches and boxes, entrance cut-outs and railway cut-outs, all equipped with enclosed cartridge fuses, the types of contacts with the fuses varying according to the conditions for which the boxes are designed, some having the well-known clamp contact where extreme vibration renders a clip fuse impracticable, while in other boxes the spring-clip fuse is used. On Board No. 2 is mounted a complete line of low-potential cut-outs of the spring-clip type, and also the type A or screw-clamp contacts. This applies also to the 500 and 2,500-volt cut-outs and fuses. In addition to the bullseye indicating cartridge fuses, several other specialties are shown, such as re-loading plug fuses and several types of panel fuses, also telephone, telegraph and fire alarm protectors.

THE LUNKENHEIMER COMPANY, of Cincinnati Ohio, has a unique exhibit in Machinery Palace, location 5-G, Block 26. It is easily identified by a large model of their valve in hand, which occupies a prominent corner of their exhibit. Pyramids of globe, angle, cross, lever and gate valves of various designs and sizes are arranged about the exhibit and agreeably offset by a black plush curtain at the side and rear. The glass cases arranged in front of the exhibit contain a smaller class of goods manufactured by the company, such as lubricators, oil and grease cups, cocks, etc., of all sizes. Neat designs of racks containing various sizes of whistles, injectors, pop valves and a variety of other specialties add to the interest of the exhibit. A new design of water gauge and oil pump for cylinder lubrication are features in themselves. Dispersed about the exhibit are pipe fittings of every description, together with whistles, safety and check valves and numerous other appliances made by the company.

OBITUARY.

P. B. CORNWALL, president of the Mutual Electric Light Company, San Francisco, died recently, aged eighty-two years. Notwithstanding his advanced age, Mr. Cornwall visited his office regularly up to within ten days of his death. A California pioneer of 1848, he was one of the few adventurous persons who gathered at Sutter's Fort prior to the discovery of gold and founded the town which afterward became Sacramento. In the earliest days of electric lighting on the Pacific Coast he became president of the California Electric Light Company, which was absorbed by the Edison Electric Light & Power Company, the latter being in turn merged into the San Francisco Gas & Electric Company. Later Mr. Cornwall, together with Mr. D. O. Mills, established the Mutual Electric Light Company. Mr. Cornwall had other extensive interests outside the electrical field. He leaves a widow and three sons.

◆◆◆

PERSONAL.

MR. HOMER E. NIESZ, of the Chicago Edison Company, has been appointed editor of the "Question Box" for the next convention of the National Electric Light Association. Mr. Niesz has already commenced work on the Question Box.

MR. JOHN V. REDFIELD, after some years in the works and in the Chicago sales office of the Westinghouse Electric & Mfg. Company, has been appointed to the sales staff of the Allis-Chalmers-Bullock interests at their Chicago office.

PROF. HARRY E. CLIFFORD has been appointed acting chief of the Department of Electrical Engineering at the Massachusetts Institute of Technology, succeeding Dr. Louis Duncan, who recently resigned to re-enter the engineering field.

MR. W. M. S. MILLER, who was in the employ of the Westinghouse Electric & Mfg. Company for about fourteen years, has joined the staff of the Allis-Chalmers Company with headquarters in Chicago.

MR. S. H. SHARPSTEEN, for a number of years a salesman with the General Electric Company, has accepted a similar position with the Allis-Chalmers Company, with headquarters at the New York office.

MR. E. M. GREEN has resigned the superintendency of the electric light and power plant at Rappahannock, Va., in order to accept the same position with the municipal electric light plant at Fredericksburg, Va.

MR. R. L. RICHARDSON, for a number of years in the Pittsburg sales office of the Westinghouse Electric & Mfg. Company, has become a member of the Pittsburg selling force of the Allis-Chalmers Company.

MR. JAMES ASHWORTH, until recently engineer of the City of Chicago, in the Department of Water Supply, has entered the employ of the Allis-Chalmers Company as salesman in their Pumping Engine Department.

MR. M. C. MILLER, one of the leading men in the alternating current department of the Westinghouse Electric & Mfg. Company, Pittsburg, Pa., has resigned his position with that company to accept a similar position with the Allis-Chalmers Company.

MR. G. FRED COLLINS, who has a very extensive acquaintance throughout the East among officials and engineers of large railroad and steel companies, has recently entered the employ of the Allis-Chalmers Company as special representative at the New York office.

MR. E. D. HUBBARD, who has been for several years connected with one of the prominent electrical establishments of Detroit, Mich., has been appointed general foreman of telegraph lines of the Grand Trunk Railroad system, his territory extending from Port Huron, Mich., to Chicago.

MR. CHAS F. ADAE, for several years in the employ of the Westinghouse Electric & Mfg. Company, Pittsburg, Pa., and lately manager of the Pittsburg office of the C. Lee Cook Company, has been appointed to the selling force of the Allis-Chalmers Company at the New York Office.

MR. J. DE SMET MAGUIRE has resigned his position as special representative of the National Electric Company, of Milwaukee, to accept the presidency of the American Electric Controller Company, of New York. Mr. Maguire's headquarters will be at his company's New York offices, No. 12 Dey Street.

MR. W. S. BARSTOW, the well-known consulting engineer and former manager of the Brooklyn Edison Company, has been elected a member of the faculty of the Brooklyn Polytechnic Institute. Mr. Barstow will serve in the Department of Electrical Engineering as consulting professor of central station practice.

MR. OTTO CLYDE ROSS, for several years employed with the Westinghouse Machine Company as engineer and salesman, and lately in the employ of the Hartford Lead, Zinc, Mining & Smelting Company as engineer, has accepted an appointment with the Allis-Chalmers Company as engineer and salesman.

MR. JOHN HUMISTON, now superintendent of underground construction and line distribution with the Chicago Telephone Company, will soon sever his connection with that company to join forces with the firm of McMeen & Miller, the well-known telephone engineers. Mr. Humiston is a Western man, educated at Lake Forest University, near Chicago, and at the Armour Institute of Technology, Chicago. He has been engaged with the Chicago Telephone Company for the past eight years, since leaving Armour Institute. In vacations during his college work, he had practical training with the Metropolitan West Side Elevated Railway and the Bankers' Electric Protective Company of Chicago. Mr. Humiston is particularly well versed in the very important work of telephone construction. In this his education has been largely in the "school of hard knocks," as Mr. George A. Damon calls it. This schooling, following the excellent training gained in college, has developed a capacity for "doing things" which is a valuable asset. Mr. Humiston has made an extensive study and done much practical work in the field of electrolysis of underground pipes for gas, water and electric services. His paper on this subject read before the New Orleans meeting of the National Gas Association in 1902 resulted in his being consulted in many cases where this problem had to be solved. He is consulting engineer for a dozen or more gas and electric companies, whose underground construction requires preventive and corrective work to be done. McMeen & Miller are undertaking the work, as electrical engineers, of the entire construction of the new independent telephone system in Quincy, Ill., and Mr. Humiston will be actively connected with that project.

JOHN HUMISTON.

MR. WILBUR M. RUTH, an engineer of wide experience in both steam and electrical work and until recently assistant to the president of the Mesta Machine Company, Pittsburg, Pa., and previously employed on the engineering staff of the E. P. Allis Company, has accepted a position as salesman and engineer for the Allis-Chalmers Company at the Pittsburg office.

MR. F. A. SCHEFFLER, who has for some time occupied a very important position on the engineering staff of the Marine Engine & Machine Company, recently resigned his position with that company in order to become a special representative of The Stirling Company, manufacturer of the well-known Stirling boiler. Mr. Scheffler's headquarters will be at the New York office of the company, 114 Liberty Street.

DR. F. A. C. PERRINE, former president of the Stanley Electric Manufacturing Company and sometime professor of electrical engineering in the Leland Stanford, Jr., University, has become a member of the faculty of the Brooklyn Polytechnic Institute. Dr. Perrine will affiliate with the Department of Electrical Engineering as consulting professor in long distance electric power transmission. Dr. Perrine is thoroughly conversant with this branch of electrical engineering and his long experience as chief engineer of the Standard Electric Company, of California, which company operates one of the longest electric transmission lines in the world, especially fits him for the position.

TRADE PUBLICATIONS.

PANEL BOARDS. The H. O. S. Engineering Company, New York.—This is bulletin No. 42, containing illustrations and price lists of H. O. S. all-copper panel boards, cabinets, etc.

SINGLE-PHASE ALTERNATING-CURRENT MOTORS. Wagner Electric Manufacturing Company, St. Louis, Mo.—Bulletin No. 68, superseding bulletin No. 66 and devoted to the well-known Wagner single-phase motor.

CONDENSING MACHINERY. Dean Brothers Steam Works, Indianapolis, Ind.—A catalogue of convenient size, containing illustrated descriptions of Dean air pumps, condensers and combination outfits for all classes of condensing plants.

PANEL BOARDS AND CABINETS. The F. Bissell Company, Toledo, Ohio.—Bulletin No. 20, being a revised edition of the former bulletin of that number and containing illustrations and prices of a large line of panel boards and panel board cabinets.

MERCURY VAPOR ELECTRIC LAMPS. Cooper Hewitt Electric Company, New York.—This is bulletin No. 5, containing illustrations of the several types of mercury vapor lamp built by this company and a presentation of the merits of the lamp.

HORIZONTAL EDGEWISE SWITCHBOARD INSTRUMENTS. General Electric Company.—Bulletin No. 4384, devoted to the voltmeters, ammeters, wattmeters, frequency indicators and power factor indicators of the horizontal edgewise type for switchboard service.

SINGLE-PHASE INDUCTION MOTORS. Stanley Electric Manufacturing Company, Pittsfield, Mass.—Bulletin No. 142, containing an illustrated description of a line of self-starting single-phase induction motors in connection with which condensers are used for starting.

TELEPHONE SWITCHBOARDS AND APPLIANCES. The Vought-Berger Company, La Crosse, Wis.—A collection of leaves in a loose-leaf binder, each leaf bearing a well executed engraving illustrating some member of the extensive line of telephone apparatus built by this company.

STORAGE BATTERY DATA AND MEMO BOOK. Electric Storage Battery Company, Philadelphia.—A pocket size booklet bound in flexible celluloid and containing some extremely useful information concerning storage batteries in general and the "Chloride" accumulator in particular.

POP SAFETY VALVES AND OTHER BOILER FITTINGS.—Crane Company, Chicago.—This is special catalogue No. 100, containing illustrated descriptions and price lists of the well-known Crane pop safety valves, and also of Crane blow-off valves, ball and lever safety valves, steam gauges, water gauges, and other boiler fittings.

RHEOSTATS, MOTOR STARTERS, ETC. Cutler-Hammer Manufacturing Company, Milwaukee.—This is a hanger 38x50 inches, containing illustrations of the principal standard apparatus and some of the special appliances built by the Cutler-Hammer Company. The various illustrations are identified by the numbers of the bulletins in which the descriptions and prices may be found.

KINSMAN REFLECTORS. McLeod, Ward & Company, New York.—A pocket size catalogue, containing illustrated descriptions with prices of the Kinsman desk, portable, piano and other reflector fixtures for incandescent lamps. A new fixture, known at No. 18-A, has been added to the line in order to meet the demand for a desk reflector of somewhat lower cost than the well-known No. 1 fixture.

DIRECT-CURRENT MOTORS FOR PRINTING PRESSES. Sprague Electric Company, New York.—Bulletin No. 221 devoted to motors and controlling apparatus for printing press and similar service. The pamphlet is handsomely executed and contains illustrations of the various types of motor and controller built by the Sprague Company, as well as illustrations of notable printing press, linotype and other equipments.

BUSINESS NEWS.

HAMMACHER, SCHEMMER & COMPANY, New York, have removed to their new building at Fourth Avenue and 13th Street.

WILLIAM A. CORRAO & COMPANY, St. Louis, report a brisk trade with their Guthrie sign flasher, which is said to be an extremely simple and reliable device.

THE KELLOGG SWITCHBOARD & SUPPLY COMPANY, Chicago, has received a Grand Prize for its telephone systems and apparatus, displayed at the Louisiana Purchase Exposition.

RENE LIONAIS has engaged in electrical contracting, with headquarters at 904 St. Urbain St., Montreal. Mr. Lionais was for ten years with Collyer G Brock, a well-known electrical contractor in Montreal.

THE LAGONDA MANUFACTURING COMPAY, Springfield, Ohio, maker of Weinland tube cleaners, announces that it has been awarded the gold medal for boiler tube cleaners by the Jury of Awards of the St. Louis Exposition.

THE ELECTRIC CONTROLLER AND SUPPLY COMPANY, Cleveland, has established a Southern branch office at 509 Woodward Building, Birmingham, Ala. The company is now represented in New York, Pittsburg, Birmingham, Denver, San Francisco and London (England).

MOLINE INCANDESCENT LAMP COMPANY has opened a branch office at No. 105 Chambers Street, New York, under the management of E. E. Anderson, and a branch office in New Orleans in charge of S. J. Stewart. Other offices will be opened as rapidly as suitable representatives can be secured.

HOLOPHANE GLASS COMPANY, New York and Chicago, has purchased the interests of the V. R. Lansingh Company, Chicago, which has been for some time the Western distributor of Holophane glassware. The Chicago office will be continued under the management of Mr. V. R. Lansingh and this will be the main office of the company.

THE REEVES ENGINE COMPANY, New York and Trenton, N. J., has closed a contract for six vertical cross-compound engines to drive the lighting and power generators for the Pennsylvania Railroad Company's East River tunnel, three engines to be installed on the New York side and three on the Long Island side. During the month of September the company closed orders for thirty-six engines.

ALLIS-CHALMERS COMPANY reports that the 5000-h.p. Allis engine and Bullock generator at the St. Louis Exposition were awarded each a Grand Prize. The Allis-Chalmers exhibit in the department of mines and metallurgy was also awarded a Grand Prize. The Bullock alternators, synchronous motors and other apparatus received a Grand Prize and the Bullock system of multiple-voltage control for motors won a gold medal.

THE BALL ENGINE COMPANY, Erie, Pa., recently received an order for two 1000-h.p. horizontal cross-compound Corliss engines direct-connected to alternators for the People's Ice, Light & Storage Company, of McKeesport, Pa. The company's shipments of smaller engines show no diminution, recent orders covering some 25 engines ranging from 50 horse-power to 350 horse-power, almost all for driving electric generators.

GENERAL INCANDESCENT ARC LIGHT COMPANY, New York, recently closed a contract for a complete street lighting system at Westerly, R. I., in the face of severe competition. The company has also closed a contract for 1250 dust and airtight outlet boxes for the new Wanamaker Building at Philadelphia. The company's Ohio branch office has been removed from Cleveland to Cincinnati, with headquarters in the Perin Building.

McMEEN & MILLER (Samuel G. McMeen and Kempster B. Miller), Chicago, have been given entire charge, as electrical engineers, of the construction of an independent telephone system at Quincy, Ill. A considerable amount of underground conduits will be laid and the cable system will be planned on the broadest lines of efficiency and economy. The company recently formed to establish the system has obtained a franchise with broad privileges.

THE MARSHALL ELECTRIC MANUFACTURING COMPANY, Boston, Mass., has succeeded the Marshall-Sanders Company in the manufacture of electrical specialties. The new company will continue the business of the old one with increased financial resources and an augmented executive staff. Mr. Norman Marshall, president of the old Marshall-Sanders Company, is the president of the new concern and Mr. F. Schoenthal is the secretary and treasurer. The company's facilities will be increased as rapidly as possible.

MARINETTE GAS ENGINE COMPANY, Chicago Heights, Ill., is rapidly increasing the number of its engines in commercial operation. In Pittsburg alone the company has installed some 25 or 30 engines of 50 horse-power and over. Three of the largest daily papers in that city are printed by motors supplied from generators driven by Walrath gas engines, and a number of office buildings and apartment houses are equipped with Walrath gas engines driving lighting generators.

THE WELLMAN-SEAVER-MORGAN COMPANY, Cleveland, Ohio, has been awarded the contract for the turbine water wheel equipment of the new power house of the Chicago drainage canal. This is said to be the second largest single contract for water power equipment in the United States, the largest equipment being one built by the same company at Sault Ste. Marie, Mich., for the Michigan & Lake Superior Power Company. The equipment will comprise four 6000-h.p. units of turbine wheels direct-connected to electric generators.

CONSOLIDATED ENGINE-STOP COMPANY, New York, recently received an order from the United States Government to equip the four engines in the Philippine power plant at the World's Fair with the Monarch automatic engine stop and speed limit system. The plant consists of a Ball & Wood engine, two Shepherd engines and a Phœnix Iron Works engine, aggregating 1500 horse-power. This company has also a number of other equipments at the World's Fair, notably those on the four large vertical Westinghouse engines, the large Hamilton-Corliss engine, the Harrisburg Foundry & Machine Company's four-valve engine, and the Greenwald-Corliss engine, all in the Palace of Machinery.

THE POWER & MINING MACHINERY COMPANY, New York, has recently closed a contract with Mr. James E. Hooper, of Baltimore, for a 25x30 two-cylinder gas engine, and two No. 8 suction producers, the plant to be installed in Mr. Hooper's new cotton mill at Woodberry, Baltimore. The engine as installed will have three rope-drive pulleys for driving to the floors of the mill, and the shaft will be extended for a flanged coupling, so that another 25x30 two-cylinder engine can be installed at a later date, it being Mr. Hooper's intention to double the mill after the first half is in operation. This is said to be the first installation of gas engines for cotton mill work.

GENERAL ELECTRIC AWARDS.—The General Electric Company has been awarded five Grand Prizes, ten gold medals, five silver medals and two bronze medals by the Jury of Awards of the St. Louis Exposition. One Grand Prize was awarded for each of the following: Curtis steam turbine; alternating-current turbo-generator installation, alternating-current generator and motors, static transformers and rotary converters; direct-current generator and motors; electric railway motors and the contol systems for single and multiple unit operation and for mining and industrial locomotives; arc and incandescent lamp and arc lighting systems. A gold medal was awarded for each of the following: Complete switchboard and controlling apparatus and application of electric motors for mechanical purposes; mercury arc rectifier; wires and cables for lighting and power; electric measuring instruments; electrical laboratory apparatus; warship turret handling and controlling apparatus; sewing machine motors; best exhibit in Electrical Department; mining locomotives; social betterment of employes. Each of the following exhibits was awarded a silver medal: Sockets, switches and wiring appliances; balance light distributing concentric diffuser steel ceiling; electric searchlights; sockets, switches and wiring appliances; Lemp irreversible automobile steering check. The bronze medals were awarded as follows: One for the lumichromoscope and the other for porcelain wares.

WESTINGHOUSE AWARDS AT THE EXPOSITION.—The Westinghouse Companies are the recipients of a long list of awards from the Louisiana Purchase Exposition Jury. The list, in brief, is as follows:

Special award in the Department of Machinery for the "Best, most complete and most attractive installation."

Grand Prizes: Three to the Westinghouse Electric & Manufacturing Company, for "Alternating current generators and motors, alternating current turbo-generator installation, static transformers, and rotary converters"—Group 67; for "Direct current generators and motors"—Group 67, and for "Electric railway motors, alternating current and direct current, and control systems for single and multiple unit operation and for mining and industrial locomotives"—Group 67; one to the Westinghouse Machine Company, for "Horizontal gas engines and steam turbines"—Groups 62 and 63; one to the Westinghouse Air Brake Company, for "Air brakes and friction draft gears"—Group 74; one to the Westinghouse Traction Brake Company, for "Brakes for electric cars"—Group 74; one to the American Brake Company, for "Driver brakes"—Group 74; one to the Westinghouse Automatic Air & Steam Coupler Company, for "Air and steam couplers"—Group 74; one to the Westinghouse Brake Company, Limited, London, England, for "Air brakes and accessories"—Group 74; one to the Westinghouse Company, Limited, of St. Petersburg, Russia, for "Air brakes and accessories"—Group 74; one to the Union Switch & Signal Company, for "Signal system"—Group 74; one to the Cooper Hewitt Electric Company, for "The development of the mercury vapor arc lamp"—Group 69.

Gold Medals: Three to the Westinghouse Electric & Manufacturing Company, for "Complete switchboards and controlling apparatus, and the application of electric motors for mechanical purposes"—Group 67, for "Alternating current, direct current, and Bremer arc lamps and arc lighting systems"—Group 69, and for "Electric measuring instruments"—Group 71; one to the Nernst Lamp Company, for "Nernst lamps"—Group 69; one to the Cooper Hewitt Electric Company, for "Vapor lamps for photo-engraving"—Group 15; one to the Pittsburg Meter Company, for "Water and gas meters"—Group 64; one to the Westinghouse Electric & Manufacturing Company, for "Industrial betterment work"—Group 138, and one to the Westinghouse Electric & Manufacturing Company, for "The housing of the working classes"—Group 136.

Silver Medals: One to the Westinghouse Electric & Manufacturing Company, for "Switches, fuses and wiring appliances"—Group 69; one to the Sawyer-Man Electric Company, for "Incandescent lamps"—Group 69; one to the Bryant Electric Company, for "Electric light fittings"—Group 69, and one to the Societe Anonyme Westinghouse, Havre, France, for "Gasolene automobiles"—Group 72.

One Bronze Medal to the Perkins Electric Switch Manufacturing Company, for "Electric switches"—Group 69.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

DECATUR.—The Decatur Light, Power & Fuel Company has designated Mr. Hubert B. Johnson, of this city, as its Alabama agent to succeed Mr. E. F. Taylor.

ALASKA.

WRANGEL.—Messrs. E. H. Lyons, Harry P. Casser and L. Milligan have secured a franchise for the construction and operation of an electric light plant.

SKAGWAY.—The White's Pass & Yukon Railroad intends to install a complete modern electric plant at the shops here and will be prepared to furnish lights to the people of the city. Orders for the equipment have been placed.

ARKANSAS.

FOREMAN.—Messrs. H. M. and E. P. McIver are making arrangements to establish an electric light plant here.

SEARCY.—The estimated cost of the new electric light plant, for which bids were recently opened, is in the neighborhood of $22,000.

PINE BLUFF.—The Pine Bluff Light & Water Company recently added to its equipment another generator, which will enable the company to greatly enlarge its service.

LITTLE ROCK.—The City Council is considering the advisability of purchasing new machinery for the electric light plant. The improvements will probably cost about $9,550.

CALIFORNIA.

OAKLAND.—The contract for the erection of the new municipal light plant has been let by the City Council.

ALAMEDA.—A proposition for the enlargement of the municipal lighting plant has been presented to the Council.

CHICO.—It is reported that the Butte County Power, Light & Water Company, of this city, has secured the franchise for supplying electricity to Sterling City.

EUREKA.—President B. Von Homeyer, of the Humboldt County Light, Water & Power Company, is perfecting the plans for the plant which the company expects to erect here.

SAN FRANCISCO.—The California Gas & Electric Corporation awarded a contract to the California Electrical Works for 12,000 four-part "Thomas" insulators for operation on 60,000 volts.

CHICO.—Mr. J. A. McFeely has appropriated 12,000 inches of the water of Deer Creek, in Butte County, to be used in generating electric energy for power, irrigation and domestic purposes.

EUREKA.—It is rumored that the sale by the Humboldt Milling Company of its electric light plant to Eureka parties is the first step toward an electric road from Eureka to Rohnerville and in time to the other towns south of Rohnerville. The company will furnish lights and power for all purposes. Mr. L. M. Hancock, the electrical engineer, of San Francisco, is said to be interested in the project.

COLORADO.

SALIDA.—The Salida Light, Power & Utility Company has been incorporated with a capital stock of $50,000.

LAS ANIMAS.—The following are the present officers of the Las Animas Electric Company: President, P. C. Scott; vice-president, W. A. Otis, of Colorado Springs; secretary, George B. Tripp, Colorado Springs; treasurer, J. W. Sargent, Colorado Springs; manager and purchasing agent, George M. Hoag.

DENVER.—The Denver Gas & Electric Company recently increased its equipment by installing a 3500-h.p. engine capable of supplying current for 45,000 16-c.p. incandescent lights. With the addition of this new unit the company expects to be able to meet all the demands for light for several years to come.

SALIDA.—A chart of preliminary plans and specifications for a water power electric plant is now in the hands of the Edison Electric Light Company, and as soon as a site for the plant can be determined upon work will be commenced. The present plan is to install a plant with a producing capacity of 2000 horse-power.

CONNECTICUT.

NORWALK.—One of the most successful electric light and power plants is the South Norwalk. It is claimed that power is furnished by this plant at half the cost at which it can be obtained in any other city in Connecticut, and that this is the principal inducement that has caused half a dozen new industries to locate here during the past two years, while it has prevented other concerns already established from moving to other points. The plant is municipal in name only, being handled independently, although the city is lighted at actual cost. Its general superintendent, A. E. Winchester, is to be congratulated on his able management. An immediate increase of the plant's capacity is contemplated.

DELAWARE.

WILMINGTON.—The National Lighting Company, with a capital of $500,000, has been incorporated.

FLORIDA.

GRACEVILLE.—Robert Boone, of Marianna, is said to have secured a franchise for establishing water works and an electric light plant.

GEORGIA.

ATLANTA.—Mr. A. Balsley has succeeded J. N. Eley as chief electrician of the Georgia Railway & Electric Company of this city.

GREENSBORO.—An election will be held here November 9 for the purpose of voting on the proposition to install an electric light plant.

WAYNESBORO.—The contract has been let for the new electric lights in Waynesboro and it is expected to have them ready for use by the first of January next.

HARTWELL.—The new electric light plant for Hartwell is being pushed to completion as rapidly as possible, and it is hoped to have it in operation in a few weeks.

BROXTON.—A. G. Garbutt has secured a franchise for the erection of an electric light plant. The plant is to be in operation by the end of this year and the town will be furnished with lights at $70 per year.

ELBERTON.—The plans have been perfected for the proposed electric power plant to be established on the Savannah River near this place. The power will be transmitted to cities in South Carolina. The plant will develop 7000 horse-power.

LA GRANGE.—The citizens of La Grange recently voted for the issue of bonds to the amount of $40,000, of which $25,000 will be expended in building and equipping an electric light plant. The City Council has had the question of municipal ownership under consideration for some time and expects to have better lighting service than by the contract system and at much less cost.

IDAHO.

COEUR D'ALENE.—Mr. B. F. Kelly is manager of the Consumers' Company, of this place.

TROY.—The City Council has granted to the Troy Manufacturing Company a franchise for an electric light plant which will furnish lights for the town.

BOISE.—The engineers for the Highland Power Company are said to have perfected plans for the restoration of the plant at Boise. The power house will be built on the north side of the river.

NEZ PERCE.—The Nez Perce Water & Power Association has purchased the Nez Perce Electric Light Plant, the creamery plant, the flour mill and the Lolo Power Company's plant and will also take over the water works system of the town. A new water plant will be installed immediately. The capital stock of the new company is $100,000 and the incorporators are Z. A. Johnson, Stephen Johnson, C. W. Lewis, J. L. Harris and T. W. Englehorn.

LEWISTON.—Reports are to the effect that the Lewiston Water & Power Company, which has been engaged in building the new transmission lines to Uniontown, Genesee, Moscow and Pullman, is to be combined with the Lewiston Light Company, Ltd., the Clarkston Water Works and other interests to form a new company to be known as the Lewiston-Clarkston Company. The total capital will be increased to $3,000,000 in order to provide for the 1000-h.p. auxiliary steam plant now building, the extension of lines 40 miles to various mines and factories, besides the four towns already mentioned, the rebuilding of the water conduits for supplying power plants and for irrigation purposes, and increasing the capacity of the company's hydraulic-electric power plants to 5000 horse-power.

ILLINOIS.

BENTON.—The municipal lighting plant of this city was recently destroyed by fire, the consequent loss being estimated at about $10,000.

ELIZABETH.—Mr. Howard Cook, of Chicago, has secured from the Village Council a franchise to erect and maintain an electric light plant.

LITCHFIELD.—A franchise has been granted by the City Council to Charles Munday, Jr., for the construction and maintenance of electric light and gas systems in this city.

LAGRANGE.—The Lagrange Service Company, Inc., recently filed articles of incorporation. The company is capitalized at $100,000. H. J. Dunbaugh and G. C. Madison are named among the directors.

COMPTON.—The Compton Electric Light Company has filed articles of incorporation, stating the capital stock to be $25,000 and naming the following directors: J. S. Richardson, L. W. Kutter and W. N. Hills.

MONMOUTH.—The Monmouth Gas & Electric Company has filed articles of incorporation. The company is capitalized at $200,000 and proposes to operate heat, light and power plants. W. A. Thompson, Charles B. Wood and Horace S. Oakley are the incorporators.

INDIANA.

PORTLAND.—It has been decided by the City Council to install an electric light plant.

DILLSBORO.—William E. Swarthout has filed a petition for a franchise granting him the privilege of building and operating an electric light plant.

FORT WAYNE.—The work of reconstructing the city lighting plant is well under way, and the extent of the alterations promises a greatly improved lighting service when completed.

KENDALLVILLE.—The city is making arrangements to expend $4550 in new electric street lighting equipment. Twenty-five new arc lights will be added, bringing the total number up to eighty.

WEST MUNCIE.—Reports state that a stock company, headed by Jerome Herff, of Peru, has been formed for the purpose of constructing an artificial lake and dam and erecting an electric power house here.

MUNCIE.—The Muncie Electric Light Company is preparing plans for the erection of an addition to its plant in North Walnut Street. The improvements, including the equipment, will probably cost about $35,000.

NEW ALBANY.—Recent reports are to the effect that the stockholders of the United Gas & Electric Company have decided to issue $750,000 bonds for the extension and improvement of its plants in this city and Jeffersonville, as well as those located elsewhere. Orders for two 500-kw. Curtis steam turbines have already been placed.

IOWA.

LA BELLE.—It is proposed to issue bonds to provide for the completion of the electric light plant.

BURLINGTON JUNCTION.—An effort is being made to establish an electric lighting plant at this place.

EARLHAM.—According to recent reports, Hill & Johnson contemplate constructing an electric light plant.

STONE CITY.—Mr. H. F. Dearborn is said to be interested in the electric light plant being established here.

HAWARDEN.—The contract for the proposed repairs and improvements to the electric light plant has been awarded to Edwin C. Bennett & Co., of Omaha, Neb., for $4,465.

SUMNER.—A twenty-year franchise is said to have been granted by the Council to a Minneapolis firm permitting them to operate an electric light and power plant in this city.

DES MOINES.—Reports state that the Iowa Light, Heat & Power Company contemplates expending about $250,000 in improving and extending its service within the next year.

OELWEIN.—The People's Light, Heat & Power Company, Inc., has been incorporated by M. E. Springer, T. H. J. Lochband and others. The company's capital stock is fixed at $75,000.

GRINNELL.—At a recent meeting of the Commercial Exchange, O. K. Cole, of Cincinnati, who, with his brother, H. Cole, and C. W. Lawrence, of Chicago, recently purchased the entire stock of the Grinnell Heating & Electric Company, outlined the plans for improvements which the company expects to carry out. Three new boilers have already been purchased and are on their way here. This will double the present capacity of the company's boilers, increasing it 450 horse-power. The boilers will all be reset and rearranged to economize space and power and the new ones will be placed in a new boiler house now being erected just back of the old plant, and which is to be thirty by sixty feet. It will have an immense smokestack five feet in diameter and 120 feet high, with a capacity of 550 horse-power. All the street mains will be overhauled and the size of the pipes increased from eight to ten inches.

KANSAS.

KANSAS CITY.—The electric light plant here has been destroyed by fire.

LINDSBORG.—A proposition is being considered by the City Council to light the town by electricity.

WINFIELD.—Winfield is to have an electric light plant and bids have been called for for furnishing the necessary material and for constructing the power house.

CLYDE.—Preparations are being made by M. E. Maggart, of Chicago, for the erection of an electric light plant in this town. Work will be commenced about November 15.

WICHITA.—The Citizens' Electric Heat, Light & Power Company has petitioned the Council for a franchise granting the use of the streets for the purpose of installing a system of electric lights.

TOPEKA.—The Edison Electric Illuminating Company, of this city, has filed a petition with the Council for a thirty-year renewal of its present franchise, which expires January 26, 1906. The matter is under advisement by the Council.

ARKANSAS CITY.—The plant of the Arkansas City Gas & Electric Light Company has been destroyed by fire, entailing a loss of $50,000, of which $3000 is covered by insurance. The plant is outside the fire limit and has no protection. This is the second time it has burned, the first fire occurring about four years ago, after which it was immediately rebuilt.

KENTUCKY.

OWENSBORO.—Work upon the foundation for the addition to the electric light plant is under way.

WEBSTER.—The Sebree Light & Power Company has been incorporated with a capital of $10,000.

PIKEVILLE.—The Pikeville Electric Light Company has recently installed a $10,000 power plant which is now in operation.

FLEMINGSBURG.—Messrs. Henderson & O'Bannon, proprietors of the electric light plant of this place, contemplate the addition of a new dynamo to their plant equipment this fall.

LOUISIANA.

CROWLEY.—The city has purchased a new engine at a cost of $35,000, to be installed in the municipal lighting plant.

MAINE.

BIDDEFORD.—The York Light & Heat Company states that arrangements are under way for installing a 75-kw. generator direct-connected to a 100-h.p. engine. Mr. Walter Stackpole is chief engineer.

BANGOR.—A. R. Gould, of Presque Isle, writes that contracts will probably be let next March for the work in connection with the construction of a dam and the development of about 3000 horse-power at Aroostook Falls.

BUCKSPORT.—The Bucksport Lighting Company was recently organized for the purpose of conducting a general electric and gas lighting business in this town. The company has a capital stock of $15,000 and is officered as follows: President, Harry L. Cram, of Portland; treasurer, A. J. Desmond, of the same city.

MARYLAND.

CHESTERTOWN.—The business men of this city are reported to be organizing a company for the purpose of installing and operating an electric light plant.

BALTIMORE.—The Baltimore Electric Power Company has been incorporated with a capital stock of $2,500,000. The incorporators of the new company are directors and officers of the Maryland Telphone & Telegraph Company, which was recently granted a franchise to furnish light and power service. The interests of the two companies, it is said, will be identical in the construction and operation of the proposed plant.

MASSACHUSETTS.

MANSFIELD.—Much needed improvements are to be made to the lighting service here.

WEST SPRINGFIELD.—Mr. Frank L. Worthy, of this city, is said to be interested in the construction of an electric light plant.

HOLYOKE.—The Electric Light Department is considering the expenditure of about $28,000 in improving the motive power of the electric light plant.

NEEDHAM.—Mr. William H. Burgess, president of the Charles River Power Company, states that machinery for 300 horse-power has been installed and that amount of power is now being utilized. The development of the additional 700 horse-power will not be completed for some months yet.

SPRINGFIELD.—James H. Forsythe, who has been connected with the United Electric Light Company in various capacities for the past 17 years, and who for the past 12 years has been superintendent of construction, has resigned his position with the company, and has been succeeded by A. H. Bunker, of Boston. Mr. Bunker has already assumed his new duties as superintendent. Mr. Bunker has had a wide experience and is generally conceded to be a man of recognized fitness for the position of superintendent, having been for the past nine years superintendent of the Edison Illuminating Company of Boston. The retiring superintendent, so far as is known, has no plans for the immediate future. He has been popular with the men in his employ during his long connection with the United Electric Light Company and has been with it during its great progress of growth from a small concern to one of the most powerful corporations in the city. The work of underground construction for the company will hereafter be in charge of W. A. Dennett, who has been with the company for some time.

MICHIGAN.

WAYNE.—Bonds to the amount of $8000 are to be issued for the establishment of an electric lighting plant in the town.

ADRIAN.—The Citizens' Light & Power Company is contemplating installing soon a new 250-h.p. boiler and a three-phase generator.

PORTLAND.—Mr. S. E. Jarvis is reported to be negotiating for a piece of property here upon which he intends to erect a large power house at an estimated cost of $180,000.

MILLERSBURG.—The citizens of Millersburg are desirous of having the town lighted by electricity, and it is possible that the Onaway Electric Lighting Company may extend its lines to this place for that purpose.

SPRING LAKE.—At a special election held recently it was voted to install an electric light system, the current to be supplied by the Grand Rapids, Grand Haven & Muskegon Interurban Company through a meter, so that the village will pay only for the amount consumed.

MANISTIQUE.—Plans have been completed for the new plant of the Manistique Light & Power Company and the contract for the construction work has been awarded to McArthur Brothers & Co., of Chicago. It is proposed to expend about $50,000 in building and equipping the plant.

KALAMAZOO.—The Kalamazoo Valley Electric Company is making preparations to build a large dam on the Kalamazoo River next spring. It will be located somewhere between Allegan and Otsego, the exact location not being known at this time. Looking toward this project, the company has asked the City Council for an extension of its franchise for a period of thirty years. The company is at present unable to meet the demands for power and it has therefore been decided to extend and enlarge the plant.

GRAND RAPIDS.—The development of the water power at Cascade by the Cascade Electric Company, composed principally of Grand Rapids capitalists, is being pushed in order that active work may be begun in the spring. It is stated that the necessary rights have been secured and arrangements completed for the construction of a large cement dam at a cost of about $20,000. It has been decided to increase the capitalization of the company from $20,000 to $150,000. Sufficient contracts for power have already been secured, it is said, to insure the success of the new enterprise.

MINNESOTA.

MINNESOTA LAKE.—It is reported that steps are being taken toward the installation of an electric light plant.

WINTHROP.—Plans are under way for the enlargement of the electric light plant and the extension of the water works.

MINNEAPOLIS.—The Pacific Power Company has been incorporated with a capital stock of $1,000,000. C. B. Darling and S. R. Mattier are named among the directors.

MISSISSIPPI.

JACKSON.—Mr. J. B. Smith was elected city electrician at the last meeting of the Board of Aldermen.

EUROPA.—Reports are to the effect that private parties are making arrangements to install an electric light system here.

NEW ALBANY.—The plans and specifications have been prepared for a $20,000 water and electric light plant, for which bonds to that amount were recently issued.

GREENWOOD.—It is reported that bonds to the amount of $123,000 have been sold, the proceeds to be used to pay for the plant of the Water, Sewerage & Electric Light Company.

UTICA.—At an election held recently the citizens expressed themselves as being in favor of a bond issue of $19,000 to provide for the establishment of water works and an electric light plant.

ABERDEEN.—The City Council has ratified the purchase of the E. M. & J. K. Jones electric light plant, and the property has been turned over to the city. The plant will probably be greatly improved and enlarged within the course of the next year. Mr. E. M. Jones is superintendent and general manager.

MISSOURI.

SEDALIA.—Reports state that it is probable that Sedalia will shortly be lighted by electricity; the proposition to establish such a plant is now under consideration by the Council.

JEFFERSON CITY.—The plant of the Jefferson City Light, Heat & Power Company was recently sold to J. N. Horner, representing a Chicago syndicate. The transfer was accomplished in consideration of $80,000.

MONTANA.

LIVINGSTON.—G. H. Hill, of Helena, has applied to the City Council for a franchise permitting him to establish a water, light and power plant here.

NEBRASKA.

OMAHA.—The Omaha Electric Light & Power Company contemplates installing shortly a 1500-kw. Curtis turbine.

GENEVA.—Gregory F. Shinkle has been granted a franchise to establish and operate an electric light plant at Geneva.

LINCOLN.—Plans have been prepared for the new municipal lighting plant here, which will be capable of supplying 450 lights, although but 328 are to be installed at present.

KEARNEY.—The Northwestern Electric Heat & Power Company has under consideration plans for extensive improvements to its equipment; these are said to include new boilers, dynamos and transformers.

NEW HAMPSHIRE.

NASHUA.—The Rockingham Light & Power Company has notified Secretary of State Pearson of an increase in its capital stock from $750,000 to $1,000,000.

WALPOLE.—The Fall Mountain Electric Light & Power Company has completed the work of placing the street lamps. Some changes were made in the location of lamps and the arc light on North Main Street replaced with incandescent lamps. The electric light poles from the town hall to the top of Depot Hill have been removed and the main line is located on Pleasant Street.

NEW JERSEY.

JERSEY CITY.—The Weiderbold Light Company's plant here has been wrecked by an explosion.

LAMBERTVILLE.—The Lambertville Heat, Light & Power Company is extending its lines to New Hope, Pa., in order to supply light and power to that town.

KEARNEY.—A resolution has been adopted by the City Council, instructing the lighting committee to inquire into the feasibility of installing an electric lighting system in the town, and if beyond the means of the town, to ask for bids for the illumination of the streets.

NEW MEXICO.

ALBUQUERQUE.—The Albuquerque Electric Power Company has been incorporated with a capital of $50,000, for the purpose of generating and distributing electricity. William L. Iliff, William B. Childers and Edward Allen are among the incorporators.

SANTA FE.—H. B. Holt, an attorney of Las Vegas, N. M., states that Eastern capitalists are now seeking investment in the Mesilla Valley, with a view to establishing a colony and erecting a large central electric power plant. Dr. J. R. Hawes is also interested in the project.

NEW YORK.

CLIFTON SPRINGS.—A new electric lighting system is being installed here.

UTICA.—The Utica Gas & Electric Company is contemplating improvements to its plant which will involve the expenditure of $40,000.

SLOAN.—Arrangements have been made by the Village Council with the Depew & Lancaster Light & Power Company to light the village by electricity.

OLEAN.—The Genesee Valley Power Company has been incorporated with a capital of $25,000, by W. L. Young, Emma D. Young and George Forbes.

ALEXANDRIA BAY.—The Alexandria Bay Electric Light & Power Company's plant has been destroyed by fire, entailing an estimated loss of $12,000.

NIAGARA FALLS.—The Toronto Niagara Power Company has awarded the contract for four turbines of 10,000 horse-power capacity to I. P. Morris Co., of Philadelphia.

BUFFALO.—The incorporation of the Buffalo Lighting Company is reported. The company has a $30,000 capital stock, and N. McMillan and L. E. Wesley are among the directors.

ILION.—It has been voted to issue bonds to the amount of $25,000, which will be used to pay off the present indebtedness on the electric light plant and to make improvements to the plant.

HOOSACK FALLS.—The Hoosack Falls Generating Company has been organized and incorporated by E. R. Case, W. Z. Roberts and P. Fitch. The company, which is capitalized at $25,000, will operate gas and electric generating plants.

SYRACUSE.—A certificate of the incorporation of the Syracuse Electric Company has been filed by S. J. Kelly, William H. Horton and M. J. Myers, who constitute the board of directors. The capital of the company is fixed at $20,000.

ALBANY.—The Suburban Power Company has filed articles of incorporation fixing its capital stock at $10,000. The company will distribute electricity throughout Niagara and Erie counties. Among the directors are E. A. Wickes and W. B. Rankinor.

LOCKPORT.—The Common Council has voted a franchise to the Niagara, Lockport & Ontario Power Company, granting it permission to erect poles, string wires and lay conduits in the streets for the purpose of furnishing electricity for light, heat and power.

PLATTSBURG.—The property of the Lozier Light & Power Company is said to have been purchased by George M. Cole and T. B. Cotter, of Plattsburg, and H. L. Merry, of New York, and a new company has been formed with T. B. Cotter as president. The contract with H. A. Lozier for lighting the streets of Plattsburg has been transferred to the new company.

NEW YORK.—Preliminary plans have been filed for the new power station to be built for the New York Edison Company on First Avenue from Thirty-ninth to Fortieth Streets. It will be three and five stories high, with a facade of granite and brick and will have a frontage of 197 feet and a depth of 347 feet. Its cost is estimated at $1,200,000. The Allis-Chalmers Company, it is said, will furnish the equipment for the plant.

CLINTON.—The citizens have voted for a bond issue of $7000 to be used in acquiring or establishing an electric light plant. Whether the present plant will be purchased, however, or a new plant installed has not yet been decided, but it is believed that the former plan will be adopted as the necessary repairs could be made and the system put in complete running order in much less time than it would take to install an entire new plant.

GLOVERSVILLE.—Mr. J. W. Fletcher is superintendent of the electrical department of the Fulton County Gas & Electric Company, which has absorbed the Gloversville Electric Light Company and the Johnstown Electric Light & Power Company. The city contract includes 245 arc lights at $86.40 per year and 21 32-c.p. incandescent lights at $45 per year, in addition to which the company also supplies 344 commercial arc lights and 11,000 commercial incandescent lights at 10 cents per kilowatt each.

ALBANY.—The Central Power Manufacturing Company, incorporated some months ago, is negotiating for the purchase of water privileges at Cossayuna Creek, near Granville. The water power at this point is now controlled by the Alexander Blanket Company, and it is understood that the power, if obtained, will be used in conjunction with the plant to be erected near Schenectady. The stream develops about 100 horse-power when the water is at normal height, and many times that during the rainy season. The company, which is headed by Charles R. Huntley, will, it is reported, maintain a plant between Schenectady and Albany, with the end in view of supplying the current for the new barge canal, besides furnishing power for manufacturing purposes.

ONEIDA.—Considerable inconvenience was caused here recently by the breaking of the main shaft in a 500-h.p. engine in the power house of the Madison County Gas & Electric Company. It took nearly two weeks to make and install the new shaft, during which time as sufficient power could not be generated to run the trolley line and the street lights patrons of the trolley line were compelled to walk in the evening. It is now proposed to develop the power at Lime Kiln Falls, about nine miles north of this city, and establish a water power plant for the generation of electricity for commercial and lighting purposes. New York and Philadelphia capitalists are said to be interested in the project and plans have been prepared for a plant of sufficient capacity to supply Madison and parts of Oneida and Onondaga counties with electricity.

SYRACUSE.—At the annual meeting of the stockholders of the Syracuse Lighting Company held recently, considerable important business was transacted, including the election of directors, the authorizing of the placing of an order for a new battery of boilers at the electric light plant to cost $25,000, the adoption of a resolution calling a special meeting of stockholders to authorize an increase in the number of directors from thirteen to fifteen, and the presentation of the annual report of the vice-president and treasurer. The directors chosen were: Robert C. Pruyn, of Albany; Stephen Peabody, Henry Seligman and James C. Bishop, of New York; Charles Andrews, Horace White, Hendrick S. Holden, Ceylon H. Lewis, Albert K. Hiscock, John Dunfee, John J. Cummins and Louis L. Waters. At a subsequent meeting of the directors the following officers were elected: President, Ceylon H. Lewis; vice-president and treasurer, John J. Cummins; secretary, Louis L. Waters; attorney, Senator Horace White; executive committee, Ceylon H. Lewis, Robert C. Pruyn, Stephen Peabody, Henry Seligman, Albert K. Hiscock and John Dunfee.

NORTH CAROLINA.

RALEIGH.—Mr. D. A. Scanlon is superintendent of the railway department of the Raleigh Electric Company.

LEXINGTON.—Bids have been called for the construction of an electric light plant for the town, the equipment to include two 85-h.p. engines and two 60-kw. alternating-current generators.

NORTH DAKOTA.

FARGO.—Bids have been called for for lighting the streets, public buildings and places for a period of one year.

WALHALLA.—Extensions are being made to the electric light plant here, which will considerably improve the service.

WILLISTON.—An application for a franchise has been made to the Town Council, for the privilege of establishing an electric light system in Williston.

OHIO.

SIDNEY.—The Sidney Electric Light Company is making arrangements to change over to a series alternating-current arc system.

MIDDLETOWN.—The Board of Public Service is advertising for bids for the contract for lighting the streets of Middletown.

EAST PALESTINE.—The Council has decided to issue bonds to the amount of $9000 to be expended in improvements to the local lighting plant.

NEWARK.—Augustus H. Heisey, George M. Heisey, E. W. Heisey and others have filed articles of incorporation for the Newark Heating & Lighting Company, capitalized at $1,000.

SPRINGFIELD.—It is reported that the American Railways Company, which controls the Springfield Railway and the Springfield Light & Power Company, has decided to rebuild the electric light plant next year at a cost of $100,000.

BELLEVUE.—Reports state that a franchise has been granted for the construction of an electric generating plant and distributing system, with the privilege of manufacturing and selling electricity for heat, light and power purposes for private and public use. The new plant is being installed.

SIDNEY.—The Sidney Light, Heat & Power Company, recently incorporated, will probably be in the market soon for equipment for its plant. This will include two 200-kw., three-phase, belted generators, simple Corliss engine and return tubular boilers. The plans for the equipment, however, have not yet been completed definitely.

URBANA.—Mr. Pope, of the Columbus, London & Springfield Electric Railway Company, and representing the Appleyard interests, is reported to have been here recently conferring with James McCroskey, superintendent of the electric light plant, and examining the plant relative to making report to headquarters in Columbus. It is proposed to either improve the present plant or construct an entirely new one.

CINCINNATI.—A resolution was passed by the Council recently to discontinue the lighting of Bond Hill by naphtha lamps and to substitute electric lights on January 1, 1905. The naphtha lighting has been done by the Welsbach Street Lighting Company of America, and the Board of Public Service was directed to give it 60 days' notice to stop on January 1, when the Cincinnati Gas & Electric Company will begin illuminating the place with overhead electric lights at $60 apiece under its contract for lighting the streets of Cincinnati.

OKLAHOMA TERRITORY.

ANADARKO.—The Anadarko Ice Plant Company has submitted to the City Council a proposition to establish an electric light and power plant in this city.

STROUD.—A franchise has been granted by the City Council to J. L. Sales & Co., of Dallas, Tex., to establish an electric light plant. The same company has also made a proposition to establish a water works system at Stroud.

ENID.—The Enid Electric & Gas Company has been incorporated, with a capital of $200,000, by L. D. Turner and R. D. W. Holder, of Belleville, Ill.; W. N. Horner, of Chicago, and John C. Moore and Clarence E. Rentchler, of Enid.

OREGON.

NORTH POWDER.—Men are at work on North Powder River, preparing for the installation of an electric power plant.

MEDFORD.—The Medford electric light plant, formerly owned by R. A. Proudfoot, is now the property of the city. Mr. F. F. Loder is superintendent of the plant.

GRASS VALLEY.—It has been decided by the City Council to issue $10,000 bonds for the purchase and improvement of the electric light and water plant at this city.

ENTERPRISE.—The electric light plant here which was destroyed by fire some time ago, has been sold to E. J. Forsythe, who will rebuild the plant on a much larger scale.

PORTLAND.—Reports are to the effect that H. L. Vors, a capitalist of New York City, has secured an option on the property of the Hood River Electric Light, Water & Power Company, with a view to purchasing.

HAINES.—John F. O'Bryant, of Baker City, Ore., has made application to the City Council for a franchise to supply this city with power for electric lights and other purposes for a period of twenty years. The proposition is under consideration.

WESTON.—Robert Jamieson, secretary of the Umatilla Electric Power Company, writes that work will probably be commenced in the spring preparatory to developing 1500 horse-power on the north fork of the Umatilla River. The plant when completed will probably have cost $100,000.

ECHO.—The Echo River Light & Power Company has filed articles of incorporation with a capital stock of $10,000. It is the purpose of the company to construct a reservoir and use water from the Umatilla River for the generation of power. An electric light plant will be installed and equipped with two engines and a 500-light dynamo.

PORTLAND.—The Mount Hood Electric Company, recently incorporated with $1,000,000 capital stock, expects to supply the city with considerably more current than is at present available. The electricity is to be generated from the Sandy River near Mount Hood and about 25 miles from Portland. Men are already at work. Mr. Edwin D. Whitney, of Chicago, who is interested to a large extent in the project, states that 30,000 horsepower will be delivered in Portland. G. W. Waterbury and C. W. Miller are the Portland incorporators.

HOOD RIVER.—Leslie Butler, H. F. Davidson and John Leland Henderson, a company of local capitalists, are reported to have secured a lease of ground from Dr. T. L. Eliot and will erect a 50-ft. dam on Hood River about half a mile from the city. The dam will be used to hold logs for the Oregon Lumber Company and the water power developed will be utilized in operating an extensive electric plant. It is hoped to have the dam completed early in December. The company expects to furnish current for lighting and power purposes in the city, preferring, it is said, to dispose of the power at a lower rate here than to secure a higher price for transmitting it to Portland or The Dalles.

PENNSYLVANIA.

DOYLESTOWN.—Wesley Keeler is now president of the Doylestown Electric Company.

SELINS GROVE.—Mr. C. E. Pugh has been granted a franchise to construct an electric light system here.

LANCASTER.—The Millstone Water & Power Company is said to be interested in the construction of a power plant at Lancaster.

CLEARFIELD. — The Central Pennsylvania Light & Power Company expects soon to install a new engine of 400 or 500 horse-power.

BLAIRSVILLE.—Dr. S. L. Clayett has succeeded Mr. Paul Graff as president of the Citizens' Light, Heat & Power Company of this town.

ALLEGHENY.—The contract for rebuilding and remodeling the electric light plant which was destroyed by fire, has been awarded to C. F. Knapp, of Allegheny, representing Langenheim, Cochran & Co., for $33,472.

COLUMBIA.—It is understood that the Columbia Electric Light & Power Company has secured the contract for lighting the city at $80 per arc lamp per year and 10 cents net per kilowatt for incandescent lights.

LLANERCH.—The following are the officers of the Eureka Light, Heat & Power Company; President, H. Hayes Aiken; secretary, H. F. Sieber; treasurer, C. L. Rihl; superintendent, F. C. Davis; chief electrician, C. B. Fulton.

DALLASTOWN.—The Borough of Dallastown has voted to install an up-to-date system of street lighting. Arc lights will be provided for the town and the current will be furnished by the York Haven Water & Power Company.

SHENANDOAH.—The Borough Council has awarded the contract for street lighting to the new People's Electric Light, Heat & Power Company at $63.50 per light per year for three years, the contract to take effect on January 1, 1905.

DALE.—The Dale Light, Heat & Power Company has been organized, with George E. Daniels, president, and Lincoln Messenger, secretary. The company has been granted right of way over the streets by the Borough Council. The power house will be 75 x 380 feet and will be erected on Bedford Street.

WILKESBARRE.—The plants of the Luzerne County Gas Company and the Wyoming Valley Electric Light Company are reported to have been sold to Forrest & Co. and Charles B. Miller, of Philadelphia, and J. C. White & Co., of New York, N. Y., representing Philadelphia and New York capitalists. The new company will have a capital of $1,500,000, and an authorized bond issue of $3,000,000. The plants of both the gas and electric companies will be extended and other improvements made at a cost of about $500,000.

YORK CITY.—The Light Committee has awarded the contract for the lighting of the city for the next five years to the Edison Electric Company at the rate of 13½ cents per light per night. The company's present contract with the city expires April 1, next, when the new one will go into effect. Although the new rate is an advance of 2 cents per light over the old one, it is considered reasonable, amounting to about $48.77 per lamp per year. There are 360 arc lights distributed throughout the city, all on the Edison circuit.

SOUTH CAROLINA.

WESTMINSTER.—The town is reported to be considering the installation of an electric light plant.

CLINTON.—Bonds to the amount of $25,000 are to be issued for the construction of water works and an electric light plant.

LAURENS.—The citizens have voted to issue $40,000 bonds to provide for the installation of an electric light plant and a sewerage system.

AIKEN.—The Carolina Light & Power Company, of this city, is preparing to enlarge its system and will probably install a new steam turbine set.

LANCASTER.—The City Council has granted to H. L. Millner, of Morgantown, N. C., a franchise for establishing water works and an electric light plant here.

FLORENCE.—A commission for a charter has been issued to the Light & Power Company, with a capital of $50,000. The incorporators are H. C. Case and William Maul Measey, both of Philadelphia.

SOUTH DAKOTA.

PIERRE.—The Mid-Western Electric Company has filed articles of incorporation, fixing its capital stock at $1,000,000.

TENNESSEE.

DYER.—The electric light plant, which was recently burned here, is to be rebuilt at once.

JACKSON.—An ordinance has been passed providing for the granting of a new electric lighting franchise.

MARYVILLE.—The Maryville Power Company is pushing the work on its line between Rockford and this place. Maryville will be lighted by electricity as soon as the line is completed.

DAYTON.—The plant of the Dayton Light & Power Company, recently completed at a cost of $5000, has been destroyed by fire. Mr. Stone, president of the company, writes that the plant will be rebuilt and that $6000 will be expended for electrical apparatus and engines alone.

NASHVILLE.—The Nashville Railway & Light Company has placed an order for a new 500-h.p. steam turbine-generator unit, to be installed in addition to the 1500-h.p. turbine installed not long ago. The new machine has been made necessary by the greatly increased demand for lighting service.

CHATTANOOGA.—It is reported that a power plant to supply East Chattanooga, Sherman Heights, Avondale and Arlington Heights with power and lights will be erected by the company recently formed to furnish these suburbs with water. At a recent meeting of the organizers of the company it was practically decided to enlarge the original plans to include the power plant.

TEXAS.

McKINNEY.—The City Council is considering bids for the installation of an electric lighting plant here.

CALDWELL.—The new electric light plant is in operation and is giving excellent service, which is much appreciated by the people of the town.

EL PASO.—The International Light & Power Company is making preparations to install a 750-h.p. turbine connected to a 500-kw generator.

WICHITA FALLS.—The Wichita Falls Electric Light Company has been incorporated with a capital of $15,000 for the purpose of supplying electric light and power to the town. The incorporators are I. H. Kempner, Galveston; Henry Sayles, Abilene, and R. C. Malone, of this city.

UTAH.

EUREKA.—Jackson McChrystal and Philip Clark have petitioned the Council of this city for a franchise, and, if granted, they will proceed at once with the work of installing electric lights and the construction of a street car line.

RICHFIELD.—Thomas Brown, general manager of the Richfield Electric Light & Power Company, writes that in addition to the steam plant which the company has just installed here, plans are being prepared for developing a water power owned by the company a few miles from the town.

SALT LAKE CITY.—J. J. Chambers, of New York City, is said to be projecting an extensive power plant which will be located a short distance from this city and operated by means of energy derived from the Big and Little Cottonwood streams. It is proposed to develop about 2800 horse-power which will be distributed for lighting purposes and the operation of mines.

VERMONT.

RUTLAND.—The Chittenden Power Company of this city has let to the Archbold-Brady Company, of Syracuse, N. Y., the contract for building at a cost of about $125,000 a power house in Mendon, a short distance above the city water works. The new structure will be located on East Creek and will complete the company's immense plant begun several years ago when the big Chittenden dam and long pipe line were built. The reservoir extends over 800 acres of ground. The new power house will have a capacity of about 2000 horse-power and the power will be utilized by the Rutland Street Railway Company and also for commercial purposes.

VIRGINIA.

HARRISONBURG.—The contracts for building the municipal electric light plant have been awarded and include the construction of the power house, the erection of twelve miles of transmission line and the installation of machinery at the power house.

PORTSMOUTH.—The Portsmouth Electric & Gas Company is engaged in replacing the open-arc lights now in use with arc lights of the enclosed type. Several new lights will be added and the entire system is being rewired. It has been necessary to enlarge the power house in order to accommodate the new machinery necessary to supply the increased power for the new circuit.

WASHINGTON.

CHEWELAH.—The Council has passed an ordinance granting to D. F. Strobeck franchises for the construction of water works and an electric light plant, work on the plants to commence at once.

ELLENSBURG.—The electric light company here is making extensive improvements at its plant; the 350-h.p. steam engine has been discarded and the plant will hereafter be operated by water power.

TACOMA.—Arrangements have been completed whereby the plant at Electron will supply the lines running to South Tacoma with electricity; they have heretofore been operated from the station at Fern Hill.

MONTE CHRISTO.—The electric plant of the American Smelting & Refining Company, which has been furnishing light to the town, is being moved to Everett. Cohn & Sheedy, of the Royal Hotel, are installing a 150-h.p. plant to furnish lights for the town.

SEATTLE.—The Diamond Ice Company has applied to the City Council for an amended franchise giving it permission to lay underground steam pipes, electric wires and water conduits and also to erect overhead electric wires in all that portion of the city lying about the southerly line of Madison Street.

EDMONDS.—John Hoffman, of Seattle, has petitioned the City Council for a franchise to establish an electric light plant. Members of the Council thought the city should own its own plant, but the people disapproved of that plan and at a mass meeting held for the purpose the Council was asked to grant the franchise.

SEATTLE.—Building Inspector Places has in his hands the letting of the various contracts in connection with the municipal lighting headquarters at Seventh Street and Yesler Way. The contract for the concrete work has been awarded to C. J. McCain at $2000, the fireproofing will be done by the Franklin Fireproofing Company, and Charles Hill secured the stone contract.

WEST VIRGINIA.

MOUNDSVILLE.—The Council is said to be investigating the cost of improving the electric light service.

WISCONSIN.

BARABOO.—The town is to have a new electric light plant, according to recent reports.

MERRILL.—Mr. F. W. King is now superintendent of the Merrill Railway & Lighting Company.

CAMERON.—There has been considerable discussion here of late as to the advisability of constructing an electric light plant in connection with the water works.

STEVENS POINT.—The contract for the construction of a water power plant, to furnish electricity for the lighting of the city, at a cost of $18,000, has been awarded to Adolph Green, of Green Bay.

RHINELANDER.—The Rhinelander Power Company, which is constructing a power plant at Hat Rapids, has let to the National Electric Company the contract for the electrical equipment. The contract calls for two 400-kw. generators, together with all necessary switchboards, transformers, etc. The water wheels will be furnished by the Dayton Globe Iron Works and will be arranged in two sets of four wheels each. The wheel pit will be sufficiently large to admit of another double set of wheels being installed should this become necessary.

MILWAUKEE.—Much discussion has been aroused here by the reports of the committee appointed by the Council to make a tour of investigation in order to determine the advantages or disadvantages of establishing and maintaining a municipal plant as compared with the present system of lighting the city by contract. Three of the members of the committee reported in favor of the city plant, while the other two favored a continuance of the contract system for the present, inasmuch as the city, they said, is not in position financially to install as expensive a plant as would be needed to meet the demands for light and power. The matter is under consideration.

OSHKOSH.—An important transfer was consummated here recently when the plant and property of the Oshkosh Electric Light & Power Company, valued at $215,000, was turned over to the Oshkosh Gas Light Company. By means of this transaction the latter company now controls all of the lighting interests of the city, the two plants and the equipment being valued at not less than $500,000. The service of the electric light plant includes 325 street lamps, besides commercial circuits of incandescent lamps and motors. Considerable new apparatus has been installed in the plant, including the erection of a steam turbine at a cost of $30,000 for operating the generating machinery. The Oshkosh Gas Light Company not only furnishes the city with gas, but has also an electric lighting department and has heretofore supplied electric power for commercial circuits in competition with the company whose plant has just been absorbed. Edgar Sawyer is president of the company, and his son, P. H. Sawyer, is secretary and treasurer.

WYOMING.

THERMOPOLIS.—The Thermopolis Electric Light Company has suffered a complete loss of its plant by fire.

CODY.—Advices state that a company financed by Denver and Eastern capitalists will shortly undertake the construction of an electric plant at the falls of the Government dam being built on the Shoshone River. Power will be generated for the mines and smelter at Kerwin, and the plans are said to also include the construction of an electric line to Sunlight, Kerwin and the Yellowstone National Park.

CANADA.

THAMESVILLE, ONT.—The citizens have decided to construct water works and erect an electric light plant.

NANAIMO, B. C.—The City Council is contemplating the purchase of the electric light plant at this place. Arrangements are also being made, it is said, to buy the new water power plant.

NEW WESTMINSTER, B. C.—E. J. Fader, of this city, is interested in the Harrison Lake Power Company, which proposes constructing a power plant to utilize 30,000 horse-power from Rainbow Falls.

MONTREAL.—The Shelby Company of Montreal, Ltd., is making arrangements to transmit current for lighting purposes to St. Andrew's and Carillton, in Argenteuil County. The power is being taken from the North River at Isle au Chats, west channel.

CHILLIWACK, B. C.—The Chilliwack Light & Power Company has succeeded in obtaining a franchise from the City Council and is now prepared to push the work on its power plant, which will be operated by means of water from Vedder Creek.

QUEBEC, ONT.—The Quebec Electric Company is starting work on the installation of its plant at St. Anne and Seven Falls. Water will be taken from Seven Falls at 374 feet. The two falls will develop at low water between 22,000 and 25,000 horse-power.

CORNWALL, ONT.—The machinery in the power house here is being duplicated. This will give a total of 2000 horse-power, which will be sufficient to meet the demands which will be made upon the plant when the new paper and cotton mills are in operation.

NORTH BAY, ONT.—The North Bay electric light plant, owned by John Bourke, has been sold to a syndicate of which A. F. Leggett, president of the North Bay Gas Company, is the representative. The company will now control the gas and electric lighting business of the town.

WOODSTOCK, N. B.—The Woodstock Railway, Electric Light & Power Company is constructing a wood and concrete dam about two miles from the town on the Meduxnakitt River. The dam is 420 feet from bank to bank with a 175-ft. spillway 25 feet above low water. Five hundred horse-power will be developed. Work was begun in June and the company expects to deliver power by December.

WESTMOUNT, QUE.—The Town Council has decided to establish and operate its own plant and has authorized the preparation of a by-law providing for a loan of $225,000, which will be used for the installation of a combined garbage consumption plant and electric light system. It is believed that with the plant once in successful operation light could be sold to a number of surrounding towns, as well as to a large number of property holders.

CHARLOTTESTOWN, P. E. I.—Expert electrical engineers have been engaged by the city to investigate and report upon the question of a municipal lighting station. They are now looking over the situation, and as soon as possible plans and estimates of cost for a suitable lighting and power plant will be prepared. Contracts with the local electric companies are about to expire and the Council has decided to fully consider the question of public ownership before binding the city to another long-term contract at the prices being asked at present.

MEXICO.

GUADALAJARA.—Louis Ugarte has made application for a concession to use 4500 liters of water per second from the Lerma River. The hydraulic plant will be built in the vicinity of La Piedad and will furnish that town wth electricity for both lighting and power purposes.

ROSARIO.—Guillermo Vega has obtained from the government a concession authorizing him to construct an hydraulic plant for motive power and industrial purposes. The concession covers 10,000 liters of water per second from either the Baluarte River or the Rosario River.

MONTEMORELOS, NUEVO LEON.—Van Voorhis Brothers, of Monterey, Mexico, have secured the contract for installing the electric light plant for the town. It will be a water power plant and the current generated will be delivered to the city over a 10,000-volt transmission line. The plant will have a capacity of 2000 lights and the equipment consists of Victor turbines and Crocker-Wheeler alternating-current generators.

American Electrician.

Vol. XVI. New York, December, 1904. No. 12.

UNDERGROUND ELECTRIC RAILWAY WORK IN PARIS.

NEW CONSTRUCTION ON THE PARIS METROPOLITAN.

BY FRANCIS PAUL.

The extensive system of subways which is now being constructed in Paris will provide the city with a vast network of lines, covering a total length of nearly 50 miles. This will afford easy access between the different parts of the city. The work of construction is now being carried on, and it is expected that the entire system will be finished within a few years. Some of the lines are now in operation and the work on others is in various stages. When completed the system will undoubtedly be the largest in Europe.

The first branch of the Metropolitan system was completed several years ago. It runs almost directly across the city from east to west, and is marked *AA* on the map. The northern section, marked *NNN* on the map, runs in a semi-circle around the northern district of the city, lying about midway between the center and the fortifications. The southern district will have a similar line, marked *SSS*, which also makes a semi-circle in this region. The two new sections join with the old at the Place de l'Etoile and the Place de la Nation.

At each of the two junction points has been erected a large underground station, or rather a series of stations, adjoining each other, seeing that the lines cross at different levels. The northern section is now complete, and trains have been running over it for some time. In the southern section the work is now being carried on, and it is expected that the tunnel and overhead structure will be finished within a few months. There are two bridges to be built over tne Seine, however, and these will delay the opening of the new line. Besides these two sections, work has already been begun on some of the other branches. Referring to the map, it will be observed that there will be no less than three transverse lines, running more or less north and south. Each of these will cross the Seine upon a special bridge.

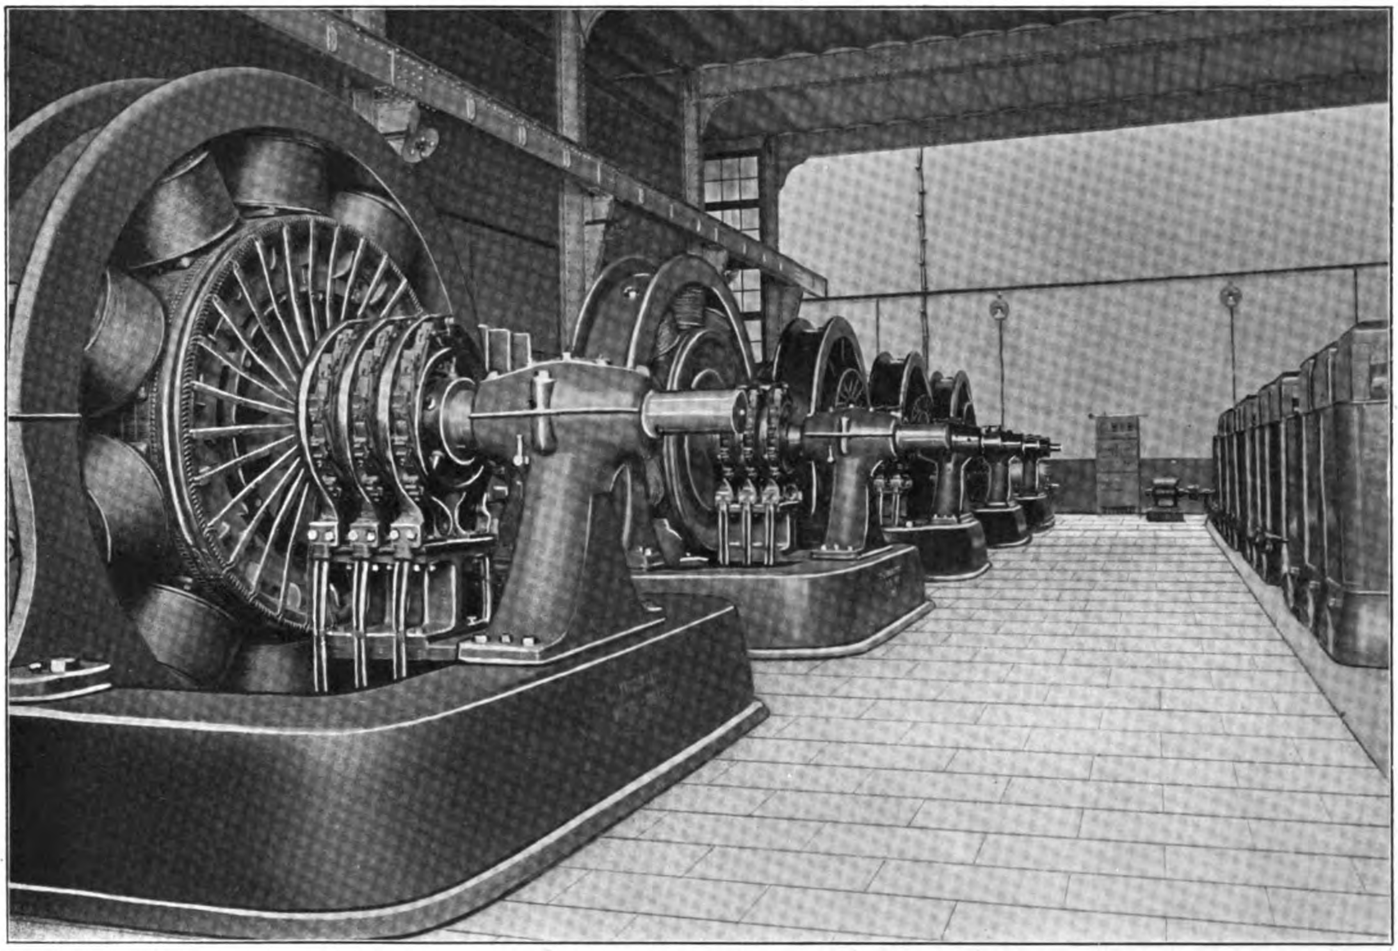

FIG. I.—NEW PÉRE LACHAISE SUB-STATION OF THE PARIS METROPOLITAN SUBWAY.

The northern section of the Metropolitan system lies partly overhead and partly underground. In general the tunnel construction has been adopted in the Metropolitan and the old section runs entirely in tunnel. The overhead construction was needed in a part of the northern section in order to pass over the tracks of two of the large railroad lines which lie in this part of the city.

The total length of the northern section is 6.1 miles, and of this about 1.2 miles are in overhead metallic structure. The latter consists of a series of bridge trusses which are mounted upon metallic columns. The structure is placed on the strip of ground which lies in the center of the Boulevards so that there is thus but little obstruction to the vehicular traffic. This line contains 23 stations; those underground are of the usual construction, having a vaulting of elliptical section with a station platform on each side of the double track.

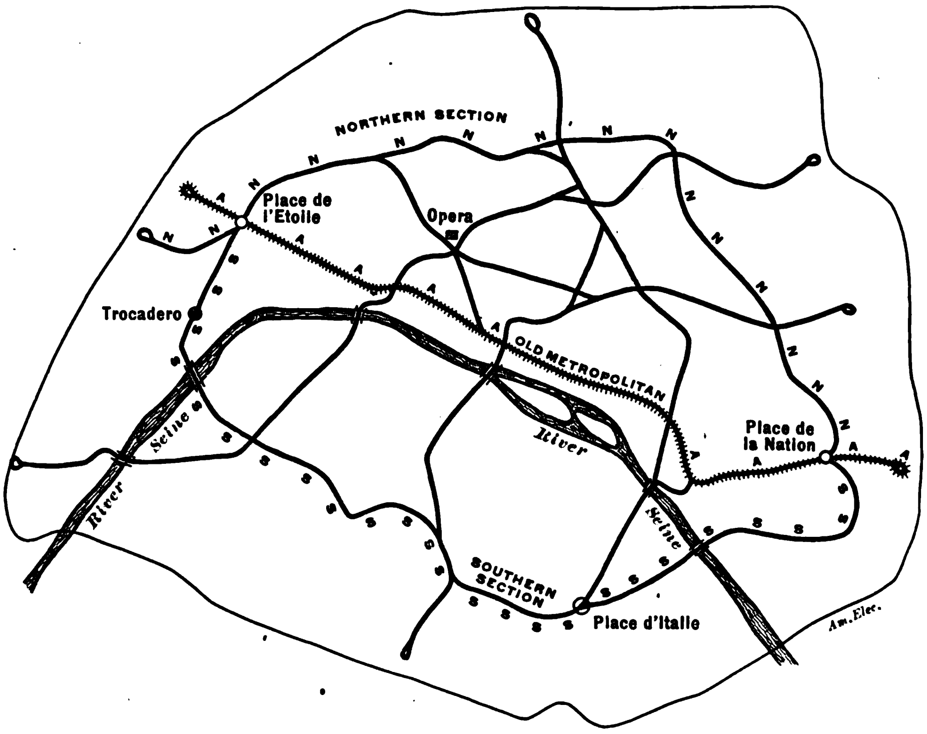

FIG. 2.—MAP OF COMPLETE AND PROPOSED SUBWAY LINES.

The construction of the underground section at the terminal points presents some unusual features. As the new line runs at a lower level than the old Metropolitan, it passes underneath it, and this makes it necessary to build the second station at a considerable depth below ground. At an intermediate point on the north line an extensive underground station has been built in order to provide for the future junction of this line with one of the newer sections, which has just been commenced. An unusual amount of underground work has been carried out at the Place de la Nation, where the north and south sections join on to the old line. The first station, that of the old Metropolitan, already existed here. It was then necessary to build a second station, lying alongside the first. The north line divides into two branches and forms a large loop which runs under the Place in a complete circle. This was required in order to facilitate the movement of the trains. Then accommodations had to be made for the southern branch, which also comes in at this point. This makes a series of underground stations which communicate with each other. Passengers descend from the street to the station on the top level, thence a set of stairways lead down to the lower stations. The whole of this extensive underground work has now been successfully carried out.

The work on the southern line presents several points of interest, first from the fact that the line lies partly in tunnel and part in overhead construction. The latter includes two overhead parts, which are joined by a section of tunnel. Besides, the line will cross the Seine at two different points near the terminal stations. This requires the construction of two bridges of special form. These are to be built in two stories, the lower for the carriage tracks and footway and the upper structure, supported on iron columns, for the tracks of the Metropolitan. One of these bridges has already been commenced and the other is to be built in the near future.

The total length of the new section between the terminals is about 8½ miles. The two parts of the overhead structure figure for 1.5 and 0.5 miles, respectively, or a total of about 2 miles. Fig. 3 gives an idea of this part of the line, showing the type of structure which has been adopted on the southern branch. The line passes along a strip of free ground in the center of the Boulevards. As will be observed, it consists of a series of metallic trusses which are upheld upon masonry pillars or in other cases upon ornamental cast-iron columns.

The lower part of the metallic structure is placed at 5.20 meters above the street level, which is the minimum distance which can be used. The grades on this part of the road do not exceed 4 per cent., except at the steep parts, where the line descends into the tunnel. The trusses have varying lengths, the maximum is 44 meters, which is used in a few cases for crossing some wide streets. In most cases the length is 27 or 22.5 meters. There are 18 stations on the southern line, with an average of 498 meters between stations. At one point on the line is a large underground station, which provides for the future junction of one of the transverse lines. The largest underground construction lies under the Place d'Italie, where there are two stations lying side by side. The second of these forms the terminus of another transverse line. Access is given between the two by a series of arches in the masonry. Of the 18 stations on the section, 6 are placed on the overhead structure and 3 are nearly flush with the ground. In the remainder the usual form of underground station has been adopted.

The new bridge, which is now being built over the Seine, will be constructed in two parts, with the middle resting upon a small island. The first part will be 114 meters between abutments and the second branch will be 90 meters long. The bridge will support an upper structure 7.3 meters wide upon iron columns to provide for the double tracks of the Metropolitan. Counting the metallic approaches on each side, the total length of the bridge will be about 400 meters.

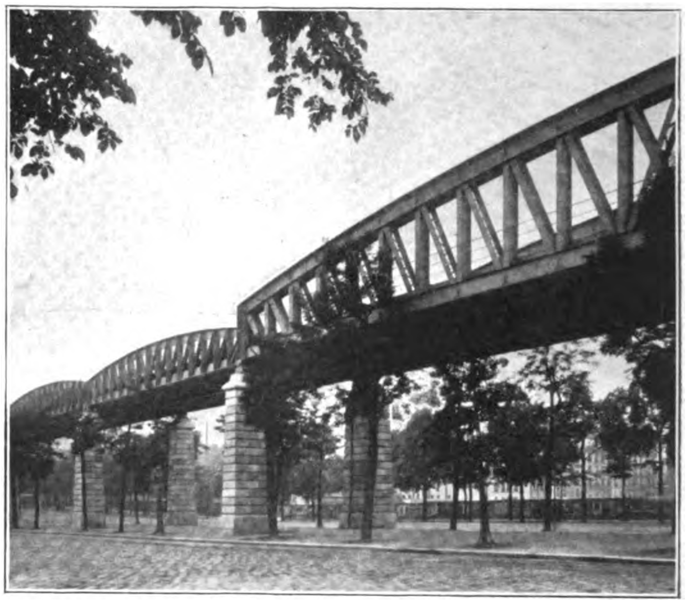

FIG. 3.—VIEW OF ELEVATED STRUCTURE.

An unusual difficulty was met with in constructing the tunnel in a part of this section. In one region the tunnel passes through the ground occupied by the ancient Catacombs. These galleries are superposed in eccentric fashion and form a series of labyrinths. On this account the ground is anything but solid, and special precautions had to be taken in order to consolidate the ground at the points where the tunnel passes for a length of 2½ miles. In the parts where the galleries are well preserved, the walls of the tunnel are upheld by sustaining pillars of masonry which are spaced at intervals of 4 meters. In the parts where the roof of the galleries had fallen in, leaving large spaces underground and forming a loose soil, the masonry pillars could not be used. It was necessary to sink wells down to solid ground, which were then filled up with concrete. This gave a solid foundation to uphold the tunnel. The pillars were braced across by masonry arches and upon the latter were built the side walls of the tunnel. In this way considerable work had to be done in order to consolidate the soil, and no less than 45,000 cubic meters of concrete and masonry are now buried in the ground in this region. This work entailed a cost of $400,000, outside of the regular tunnel construction.

The trains which are now running on the Metropolitan are made up of motor cars and trailers. The cars have a central passage, resembling the American type. The motor cars have a separate compartment at one end which is fitted with the controller and other apparatus for the motorman. Sliding doors in the side of the car have been adopted in order to save time in entering or emptying the car. The motorman has access to the cabin by a small door in the end of the car. First and second-class cars are used; the external appearance is the same, and the only difference lies in a slightly better finish in the interior.

The arrangement of the train differs according to the needs of the traffic. Thus, in certain hours of the day, when the traffic is light, a four-car train is employed. It is made up of a motor car and three trailers. In hours of heavy traffic two such trains are coupled together to form a single train of double capacity or about 100 tons load. The usual method of coupling is to place a motor car in the front of the train and a second in the rear. The cars have two motors each. These are of the double-reduction type, with a motor placed on each axle of the car. Some of the cars are equipped with Thomson-Houston and the remainder with Westinghouse material. Both have proved quite successful up to the present. The Thomson-Houston motors are built for 150 horse-power and work on 500 to 550 volts. The motors have been built at the Paris shops and weigh 2.5 tons when complete.

Since the very disastrous fire which occurred in the tunnel of the new section, in which two trains were burned and a great number of lives lost, measures were taken to avoid the recurrence of such accidents in the future. A new type of car has been adopted which will be entirely fire-proof. The car body is to be built of metal, combined with fibro-cement or asbestos board. The motorman's cabin, which occupies the front part of the car, will be considerably enlarged and at the same time separated by two fire-proof partitions from the part of the car occupied by the passengers. The two partitions will have a space of one foot or more between them, thus leaving an air space. This disposition will give a good protection for the interior of the car in case a fire should occur in the cab. Advantage has been taken of the enlargement of the cab to place the starting resistances for the motors in this part of the car. At present the resistances are placed underneath the car, where it becomes difficult to look after them.

The new car will be somewhat shorter than the present form. This will diminish the distance between axles and allow the car to pass more easily around the sharp curves which occur on the lines. These projects have been submitted to the Administration and there is no doubt that they will be carried out before long, and there will be but little danger from fire to the train. Should a short-circuit occur there will be little or no combustible material, and consequently the damage will be but slight.

A number of new sub-stations have lately been constructed in order to supply current for the new lines, and others of similar disposition are soon to be built. The current for the Metropolitan lines is furnished by the large central station which has been recently described, and the primary current, which is generated at 5000

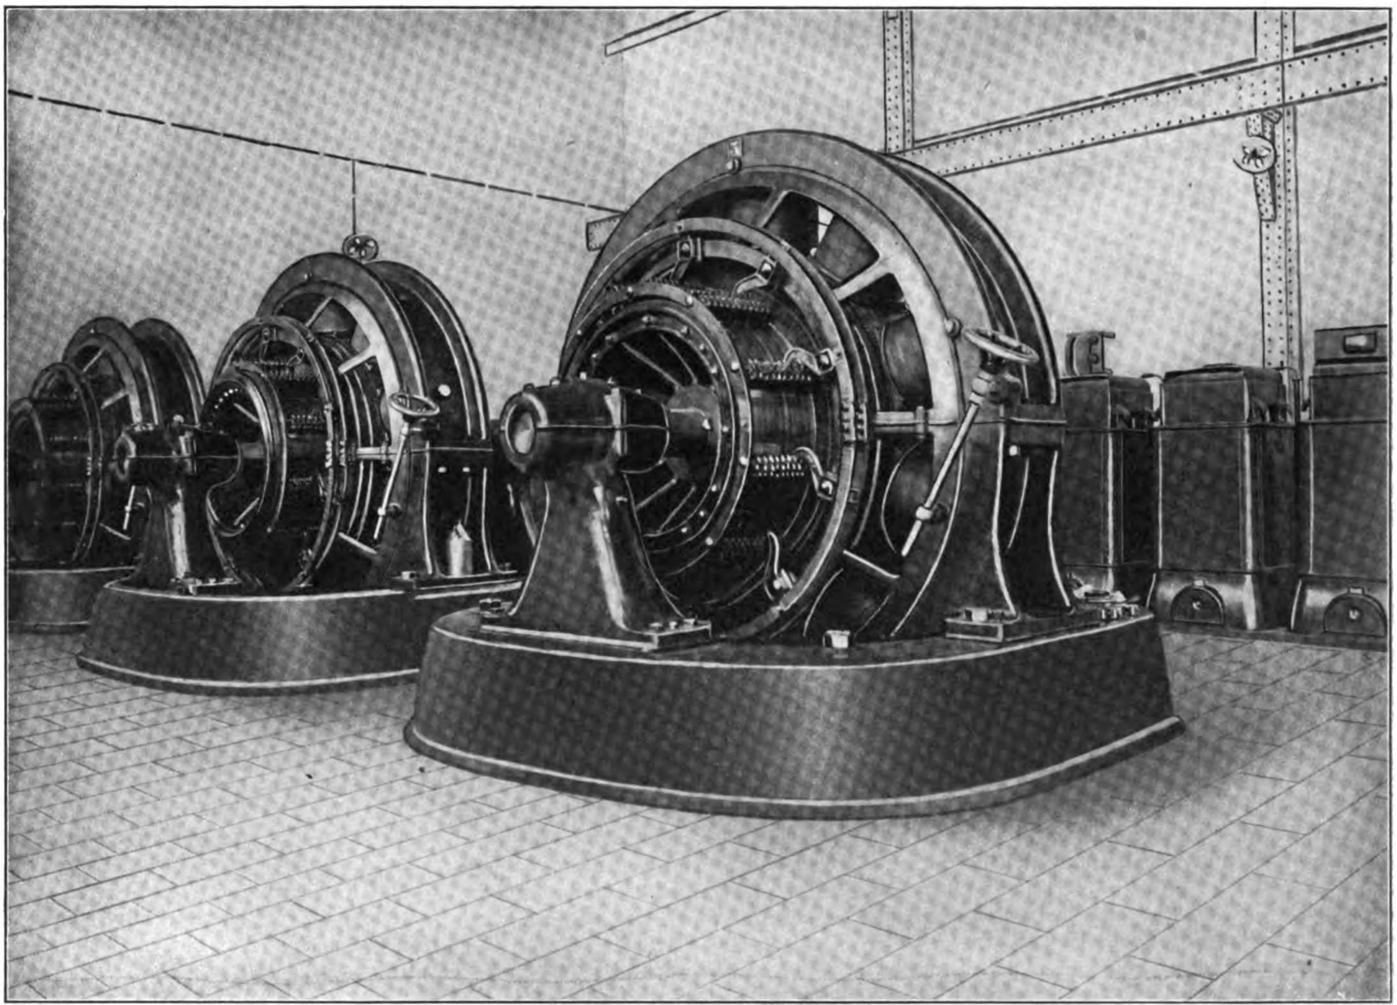

FIG. 4.—BARBE'S SUB-STATION OF THE PARIS METROPOLITAN.

volts and 25 cycles, is sent through underground feeders to the sub-stations, which are located at different points of the city. The sub-stations lower the voltage and furnish direct current at 600 volts for the third rail. Two of the largest of the new stations are illustrated herewith. At present there are five stations in all, which furnish current to the new and the old lines. The equipment of all the stations is about the same, only differing as to the capacity of the transformers and rotaries. Two of the stations are underground and are placed in masonry chambers under the street. The three others are overhead.

One of the newest of the sub-stations is shown in the engraving. It is known as the Barbe's plant and supplies part of the northern branch. This station contains three complete groups of transforming apparatus. Each group includes a six-pole, 700-kw. rotary converter of the Thomson-Houston pattern, built by the Postel-Vinay Company, of Paris, and a bank of three transformers of the same make.

Fig. 1 shows the Pére Lachaise sub-station, which is one of the largest and has recently been equipped with five groups of transforming apparatus of 700 kilowatts. Each of the rotary converters has a bank of three transformers and the general arrangement is the same as before. These stations have a switchboard for the primary and another for the secondary circuits. The transformers are placed over a pit and are cooled by a motor-driven fan.

The primary current is brought to the different sub-stations by three-conductor, lead-covered cables. The circuits which supply the sub-stations have been laid out so that the latter can be fed either from the Metropolitan central station or from one of two other large stations in the city belonging to private companies, the Triphase and the Moulineaux plants, and contracts have been made with the two companies to furnish current when needed.

One of the most difficult pieces of work in the construction of the new lines has been the crossing point of three tunnels which lie under the Place de l'Opera. At this point there are three lines which cross each other, and the tunnels are superposed one above the other at different levels. In order to provide for the crossing of the tunnels so as to allow the future work to be carried out in the lower part without interfering with the upper tunnel it was decided to build a solid structure at this point which should serve to hold the three tunnels. The rails of the lowest tunnel lie as low as 16 meters below ground. What made the work especially difficult is the presence at that depth of a stratum of water-logged sand. Accordingly, it was decided to build the structure upon three masonry pillars.

The three pillars were sunk by means of compressed-air caissons through the sand layer 20 meters below ground. This afforded a solid foundation, which supports a system of arches and iron work. This is arranged in the form of a hexagonal block embedded in the ground and flush with the surface. The three tunnels run through the block and each is independent of the other, so that future work can be carried on in the lowest line without hindering the traffic in the upper line, which will be the first to commence operation. The lower lines will be completed later on. The three masonry pillars which serve for the foundation have sections of 8 by 16, 20 by 8 and 25 by 8 meters, respectively. Upon this is built a series of masonry walls, while the flooring and roof of the tunnels are formed of I-beams. The walls of the masonry construction are finished at the top by a roofing of metallic beams, which support the roadway overhead. Each of the new lines will have a large underground station at this point and these will communicate with each other by stairways. The lowest station's platform will be at a depth of 15 meters. Spaces have been left for elevator shafts, and it is expected to equip the lower stations with electric elevators. At present this construction is finished and the roofing at the street level is being put in place.

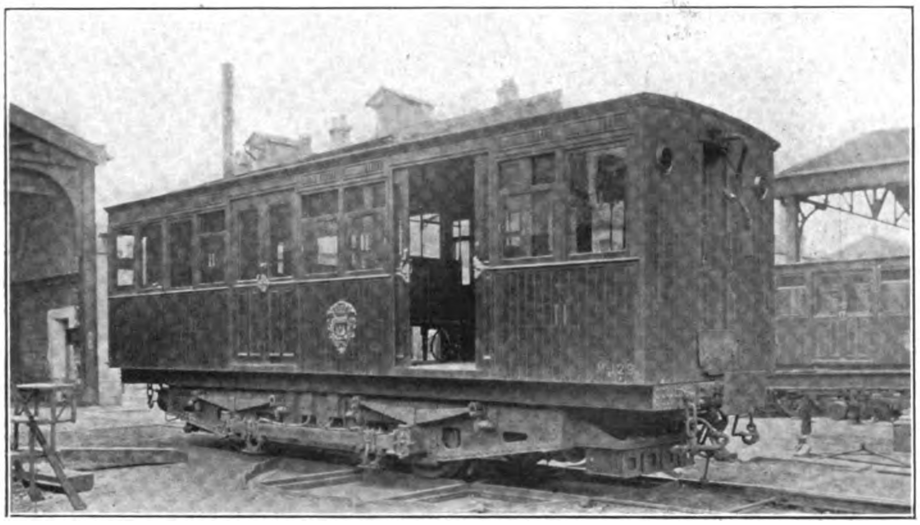

FIG. 5.—VIEW OF OLD TYPE OF MOTOR CAR.

RAPID TRANSIT AND THE ELECTRIC LOCOMOTIVE.

BY HOWARD S. KNOWLTON.

The development of the electric railway illustrates a remarkable process of evolution. Although the changes in methods and equipment which have marked the growth of electric transportation during the past ten or fifteen years are for the most part logical, they have revolutionized many phases of urban life, and have greatly influenced even rural existence. Step by step the electric motor has advanced in its conquering progress, until to-day, having almost completely driven the horse from the rails, it threatens the long held supremacy of even the steam locomotive.

Street railway traffic in cities and towns has nearly always been handled best by individual motor cars, although the use of trailers in rush hours still meets with favor in Chicago, and even in some cities as small as Denver. In general, however, the electrict locomotive finds the crowded street a poor field of action, and its economical use has come to require a private right of way as a prime necessity. Even the elevated railway and subway systems of New York, Boston and Chicago have inclined to the use of self-propelling cars within the last three or four years through the successful operation of the so-called multiple unit system, which enables any number of cars to be run grouped together in a single train, controlled by one man from the platform of any car. Strictly speaking, an electric car which hauls one or more trailers along a track is a locomotive, but the railroad man classifies it more correctly as a "motor car," reserving the title of "electric locomotive" for a piece of rolling stock whose end and aim is to haul other cars and which generally does not carry paying passengers.

Up to the present time the electric locomotive has found but a limited use in railway work. For some years it has been used extensively for hauling trains of ore cars in mines, and to a large degree it has proved convenient and economical in the handling of raw material and completed products in the yards of manufacturing establishments. Perhaps the only notable application of electric locomotives to heavy railway work has been the adoption of these machines nearly ten years ago by the Baltimore & Ohio Railroad for the purpose of hauling trains in the well-known Belt Line Tunnel at Baltimore—an enterprise which bears the reputation of entire success. The time has now arrived, however, for a battle royal between electricity and steam in suburban service, and in its choice of electric locomotives for the handling of all traffic within twenty-four miles of New York on the Harlem division, and within thirty-four miles on the Hudson River division, the New York Central road has driven the entering wedge which may finally displace the steam locomotive from the suburban field. The great Pennsylvania railroad station to be built in New York and its approaching tunnels are of like significance, but the electrification of strictly suburban service on the former road will be more complete from its beginning, according to present plans. Ultimately there is little doubt that electric trains will be run in an hour and a half between Philadelphia and New York—a distance of ninety miles. It requires no great stress of imagination to picture the day when the entire main line of the New York Central system from New York to Buffalo will be operated by electricity generated by Niagara and Hudson River power. That day may be long in coming, if the conservatism of the past be a criterion, but the future prospects of more costly fuel will have their share in causing the transition to be made. It is a great mistake, however, to assume that the steam locomotive is at present on the road to the scrap heap because two large trunk systems have adopted it for suburban service outside a single city. Some serious limitations attend the application of electricity to general railway service, and there are many obstacles to be overcome before the iron horse can suffer race extinction. Before considering some of these limitations it is worth while to touch upon some of the salient points of the New York Central's recently ordered electric locomotives and to compare them with the gigantic steam-driven machines which haul the bulk of traffic on existing railroad systems. Realizing that the technical press has already briefly described these electric locomotives, the writer hopes to accentuate their striking features without undue repetition.

Small resemblance exists between these electric locomotives and their steam prototypes. The frame is of cast steel; the wheels and trucks are of substantial design also; but the absence of the usual enormous boiler, cylinders, connecting rods, stack and tender results in an affair which looks more like an iron box mounted on wheels than anything else. The cab is built in the middle of the locomotive, and the machine will run equally well forward or backward without turning around. Of course, the steam locomotive will do the same thing, but the electrical horse has no front and rear ends, each end being front or rear according to the direction which happens to be taken. Practically none of the mechanism is visible—a marked contrast to the old-time locomotive. The new machines are equipped with electrically driven air compressors for operating the brakes and whistles, a bell and sanding device, and an electric headlight at each end. The cabs will be heated by electricity, and the motive power is furnished by four 550-h.p. motors capable of being overworked up to a total of 2800 horse-power. This means that each machine is half as large again as the largest steam passenger locomotive in existence, as far as power is concerned. They are designed to pull light trains at speeds as high as 75 miles per hour, and when it is desired to make fast time with the heaviest limited Pullman trains, two electric locomotives can easily be coupled together and operated by a single driver. This is made possible by the multiple unit control system, which is very similar to that used on the Boston and Manhattan elevated trains.

It is interesting to compare the electric machines with a typical surburban steam passenger locomotive, such as is used by the Philadelphia & Reading Railroad. The electric locomotive weigh 95 tons, against the steam's 100; the length of track occupied by its wheels is but 27 feet, against its rival's 30 feet 9 inches; its driving wheels are but 44 inches in diameter, against the Reading engine's 61⅝ inches, while the steam machine has a "tractive effort" or horizontal pulling force of but 18,000 pounds, compared with 22,800 pounds in the electric locomotive. Even the latter can be considerably exceeded for short intervals without injuring the motors. Comparing the New York Central machine with one of the largest passenger locomotives in the world—the 175-ton engine of the Santa Fé system—the steam machine requires 62 feet 10½ inches of track to accommodate its wheels, or more than double the length taken up by the electric locomotive, while with a weight of 74 tons upon its 69-inch driving wheels it can develop but 22,200 pounds horizontal pull. In other words, the Reading engine, especially designed for rapid acceleration, has a pulling force of but 180 pounds for each ton of its weight; the Santa Fé machine has 127 pounds tractive effort per ton of its bulk; while the New York Central outfit will easily show 240 pounds tractive force per ton of its weight. A great advantage of the electric locomotive in this connection is the uniform pull exerted throughout each revolution of each driving wheel, made possible by the rotary motion of the motors, as contrasted with the reciprocating mechanism of the steam engine. This means, of course, that the electric trains can attain full speed in a much shorter time than trains propelled by steam.

Several other striking advantages are noteworthy. The electric locomotive entirely does away with all the cinders, soot, smoke and disagreeable gases now inseparable from steam railroad travel; it is easier on the roadbed and track, because there are no unbalanced parts in rapid motion which pound the rails at every turn of the wheels; it allows tunnels to be traversed in comfort and with much greater safety, as there is no obstruction of signals by a smoky atmosphere; it takes up less room in stations and roundhouses, requires no stopping for coal or water, and suffers no delays due to tardy "firing up" before runs; it wastes no energy when standing still; involves no possible danger of explosions and consequent loss of life; it is but one-half as likely to be totally disabled as is its steam-driven competitor; and last, but not least, the electric locomotive demands no incessant shoveling of coal to the point of physical exhaustion by a fireman. Then, too, it is probable that the cost of keeping the newer machine in good trim will compare very favorably with the maintenance or ordinary locomotives, in view of the large duplication of simple and rugged parts in the electric locomotive and the absence of complicated valves, piping, link motions, balancing mechanism, etc. Certainly the electric machine can be very easily handled in the repair shop in the absence of the tremendous boiler common to all modern high-powered locomotives. It is difficult to realize the change in comfort which the application of the new service to the New York Central tunnel in New York will inaugurate.

Electric locomotive traction has to win its spurs, however, before it can be generally applied to railroad service in widely separated parts of the world. It has not been demonstrated thus far to the satisfaction of hard-headed transportation experts that it is enough cheaper than present methods to warrant its adoption in cases where traffic is not extremely congested. One must not imagine that the elimination of many of the inconveniences of steam locomotion means that the adoption of electric motive power has no drawbacks. Breakdowns in equipment cannot always be prevented, even with motive power designed for continuous service, and the light of much experience is needed before the conservatism of the steam railway world can be convinced that electricity can be commercially applied to trunk line operation. We may escape "leaky boilers," "poor coal" and "low steam" only to find ourselves delayed by "short-circuits," "blown fuses," "armature burn-outs," "poor contacts," and other sources of failure; the snapping of overhead wires, and accidents to which powerhouse engines are liable—all are fraught with power to incur great inconvenience. The very concentration of the power supply in a few large prime movers makes any delay or accident all the more serious. The bursting of a single steam pipe may tie up a whole division—something most improbable with present methods of operating railways, where each engine carries its own power station upon its trucks. It is not easy to exaggerate the loss in time and money which would result from even an hour's blocking of the suburban traffic of a great railroad system like the New York Central through the failure of some small but important link in the chain of energy transformations which connects the power-house coal pile with the wheels of the electric locomotives. At the best, the adoption of electric motive power means increased complication of equipment in power-house, line and substation, or distributing point, construction. There are many unsettled operating and maintenance problems which only experience can solve. The handling of suburban traffic of a city like New York or Boston, complicated as it is with transcontinental through travel, is a very different proposition from operating either street or elevated cars and trains.

Within the last few months many absurd assumptions have been made by enthusiastic writers regarding the high speeds which can be attained through the use of electric motive power. These assumptions have largely been based upon the now famous Berlin-Zossen tests, in which a maximum speed of 131 miles per hour was actually reached upon an experimental line built and operated without regard to cost for the sole purpose of securing data upon the uncertain features of high-speed electric railway operation. Although no special difficulty was encountered in running at this speed after the track, roadbed and rolling stock had been brought up to the pitch of perfection which safety demanded, the results of the trials showed conclusively that for the present, at least, such high speeds are not commercially practicable. The gain by running so fast does not justify the expense as a business enterprise. Mr. Arthur M. Waitt, recently superintendent of motive power on the New York Central road, not long ago said, in regard to high-speed operation:

"To one who has not had constant experience in running at high speeds on a locomotive, it may be a matter of surprise to know that it is not infrequently the case that engineers hauling such high speed trains as the famous Empire State Express in coming to a terminal station after a 140-mile run are so completely exhausted and devoid of physical as well as nervous strength as to be hardly able to get down from their engines, this being especially the case where trains have been late and it was necessary to make extremely high speed. When it is realized that the average speed of the Empire State Express is considerably less than 60 miles an hour, it will be seen that the nervous strain upon an operator by increasing the average speed to say, 75 miles an hour, would be almost beyond human endurance, at least for any great length of time, so that when high speeds are considered in the future, the nerve endurance of the operators of trains will have to be given careful consideration."

The great field of electric locomotives in rapid transit is that of suburban transportation, and even this field is to some degree limited. Short interval train service is a prime necessity. Where the headway of trains exceeds half an hour, roughly speaking, there is great danger of wasting money in attempting to handle the traffic electrically. Trains of from one to four cars can be operated at half-hour intervals or less, where the traffic demands such frequent service, better by electricity than by any other known motive power. In some cases branch line electric operation will be found advisable as the art advances. The day is not yet apparent when the haulage of long, heavy freight and passenger trains at wide intervals over long stretches of sparsely settled country can be profitably done by electric to the exclusion of steam locomotives. The electric railways have much to teach the steam lines of the country, but the experience of the latter, bought by more than half a century of practice, must be well considered in any future work undertaken. The requirements of twentieth century transportation are not going to relax, and the high speed electric service of the future sorely needs, in the interests of safety and economy, the best thought which long years of operating experience can produce.

PURIFYING BOILER FEED-WATER.

BY R. T. STROHM.

One of the greatest sources of trouble and worry in the management of steam boilers is impure feed-water, and there are very few plants that are wholly free from this bugaboo in one form or another. Most commonly, the impurities are of such a nature as to form what is known as boiler scale, which is a deposit of sediment and mineral matter on the water surfaces of the plates and tubes. This deposit may be soft or hard, light or heavy, and varies in composition in different localities. In all cases, however, its deleterious effects are the same. It retards heat transmission and renders the plates and tubes liable to overheating.

Not infrequently, the feed-water is corrosive in its nature, and in this condition it attacks the iron of the shell and tubes, eating away the plate, rivets and stays, weakening them, and rendered the boiler unsafe at the original working pressure for which it was designed. Of the two evils, scale and corrosion, the latter is by far the more insidious and difficult to detect. Indeed, it is frequently almost impossible to notice it, especially if the area which is corroded is of considerable extent and the corrosion is uniform in depth and character. In such a case, if corrosion is suspected, a hole may be tapped into the plate to determine its thickness, after which a plug may be screwed in to prevent leakage. If the corrosion is confined to spots, or small areas, it will reveal itself very easily, and the depth of the indentations can be determined by mere inspection.

The impurities in the water which cause scale and corrosion may be absorbed by the water in either of two ways. Water being a universal solvent, it takes up various mineral substances with which it comes into contact as it filters through the earth, or drains off the surface into the rivers and lakes. The amount of impurity thus absorbed depends upon the nature of the soil and the season of the year. For it is acknowledged to be a fact that during prolonged periods of dry weather there is more rapid scale formation than during the rainy season. The explanation lies in the fact that during the continued drought, the water supply has been for a longer time in contact with earthy material, and is therefore impregnated to a greater extent than during the wet season, when much of the water is simply surface drainage instead of having percolated through the earth. On the other hand, the surface water is liable to contain much organic matter, of vegetable and animal origin.

The second method by which water may become impregnated with impurities is by reason of pollution from the discharge of refuse from chemical and other manufacturing establishments located on the banks of streams or lakes, or by the sewage from towns and cities similarly located.

The treatment of boiler feed-water is, in many ways, analogous to the treatment of bodily ailments. There are a large number of different impurities just as there are numerous physical ills. Each of these must be treated in a specific way, just as a bodily illness must be treated according to its nature; and before any intelligent idea of the means of treatment can be arrived at, it is necessary to analyze the water and discover the amount and kind of impurities, just as it is essential to diagnose a case of illness to determine the procedure to effect a cure.

Boiler feed-water may be purified by any one, or more, of three separate means. First, by the use of heat; second, by the use of filters, and third, by the use of chemicals. In the first class, the action is purely thermal. In the second, it is simply mechanical. In the third, definite laws of chemistry are brought into play.

The purification of feed-water by the action of heat, supplied either by live or exhaust steam, was touched upon in a previous article dealing with feed-water heating. This was unavoidable, as the heating and the purification are so closely allied in many cases as to preclude individual treatment. There is this point to be observed, however: Exhaust steam heaters cannot raise the temperature of the feed-water above the temperature of boiling water under atmospheric pressure, which may be taken at 212° Fahr. Now, if there are no other impurities in solution except carbonates of lime and magnesia, the exhaust feed-water heater will do very well, since it will not only return a considerable amount of heat to the boiler which might otherwise go to waste, but it will raise the temperature of the feed-water sufficiently to precipitate the carbonates. But if the sulphates are present, no amount of heating by exhaust steam will purify the water. A live steam purifier which will raise the temperature of the water to approximately 300° Fahr. is the sole recourse in this case. The principle involved in the action of this purifier is simple. Sulphate of lime and sulphate of magnesia are both readily soluble in cold water; but they are just as insoluble when the water is above 290° Fahr. Consequently, by raising the temperature beyond the point of solubility, these impurities are precipitated. The desirability of freeing the water from these sulphates before feeding it to the boiler may be realized when it is stated that of all scale-forming substances these are the most to be dreaded, because of the hardness and tenacity of the deposits when once they are baked upon the tubes and plates. The removal of this incrustation then becomes a matter of considerable hard work for the fireman, done in a most uncomfortable position, especially in cleaning the shell of a return tubular boiler.

The precipitation of these impurities by heat is not a process which begins and is completed in the instant during which the water acquires the necessary temperature. The precipitation is gradual, and extends over a considerable period including temperatures, both below and above 290° Fahr. Hence, it is not reasonable to expect that a feed-water heater and purifier will wholly prevent the formation of scale in the boiler.

To do so, the heater would need to be of such capacity that precipitation would be complete before the water left it. Also, the rate of flow of feed water would need to be so slow that none of the precipitated impurities would be carried along with the current, into the boiler. In the great majority of cases close competition in the heater trade has reduced the size for a given amount of work to the minimum, and it is doubtful whether many purifiers do more than a part of the precipitating within themselves. It is much more common to find a heater too small for its work than to find one which is too large. Yet, it must be apparent that it is far better to err on the side of too great, rather than on the side of insufficient, capacity.

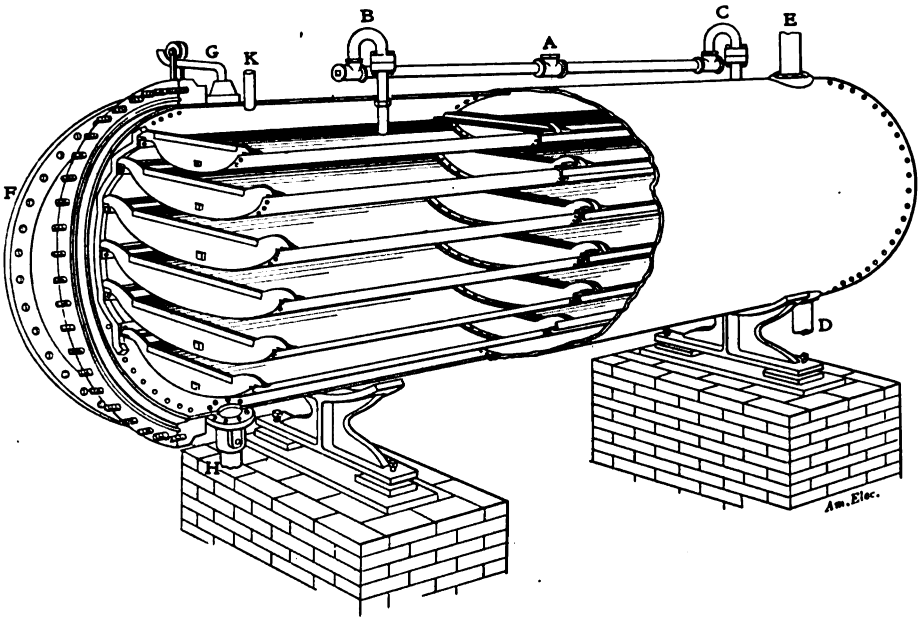

FIG. 1.

A live steam purifier which has many good points in its construction is illustrated by Fig. 1. It consists of an outside cylindrical shell made of steel plates riveted together, since the purifier is subjected to boiler pressure. A number of parallel bars of angle iron are riveted to fittings and extend longitudinally from end to end of the shell, forming supports for a number of tiers of pans. These pans are slightly dished, and are made of thin steel plates riveted to cast iron ends. The feed-water enters at *A*, and is distributed by the branch pipes *B* and *C* so as to be discharged into the upper tier of pans. From these upper trays it overflows into the second, then into the third, and so on until the bottom of the heater is reached, after which it is drawn off at *D* and allowed to flow into the boiler. It is evident that since the interior is filled with steam at boiler pressure, the water will flow by gravity into the boiler, if the heater be placed at a slightly higher level than the water level in the boiler.

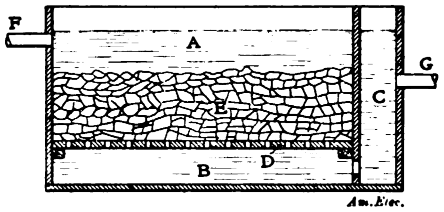

FIG. 2.

The live steam enters at *E*, and, coming into contact with the cooler water, heats it to a temperature sufficient to cause precipitation of the impurities. This action is hastened by reason of the fact that the water is broken up into many thin sheets. The precipitated impurities adhere to the pans and accumulate until it becomes necessary to clean the purifier. To do this, the head *F* is removed and swung out of the way by the crane *G*. Then the pans are taken out and the scale knocked off them. To facilitate this cleaning operation, the pans are divided at the middle, instead of extending the full length of the shell. The pipe *H* connects to a blow-off and serves to remove much sediment. A gauge glass is placed between the pipes *K* and *H* to show the amount of water in the purifier at any time.

One of the particularly important features of this purifier is its capacity. From the relative sizes of the inlets for water and the shell, it will be seen that the water must travel some length of time before it can leave the heater. This furnishes ample opportunity for the greater part of the precipitation to occur within the heater, leaving the boiler free from deposits of scale of any serious consequence. The large amount of surface exposed to catch the impurities is another valuable feature, while the troughs formed by the pans or trays serve to catch and retain the larger portion of the mud which may be carried in with the feed-water.

Filtering of the feed-water is resorted to only when the impurities are mechanically suspended in the water and can be removed by a straining through some such medium as coke, charcoal, hay, cloth, pebbles or the like. The impurities which may be removed by these means are mud, sand, oil, organic matter, and, in fact, all matter which is not in solution or in chemical combination with the water. Muddy water may be purified also by simply allowing it to stand for some time in settling tanks, with little or no circulation, when the mud will be precipitated by the action of gravity. The size of storage and settling tanks which would be required for a large plant makes this method impracticable, except in small installations. To be effective and continuous in operation, filters should be in duplicate. For, as the filtering medium removes the impurities from the water, the efficiency and capacity must eventually lower, due to the clogging of the passages. While one filter is being cleaned, then, the other may be used. This assures a clean filter always in readiness for any emergency. The filtering medium should not be expensive, and the construction of the filter should be such as to make it easy to clean. A simple and cheaply constructed filter is illustrated in Fig. 2. It consists of a wooden tank having three compartments, *A*, *B* and *C*. A perforated bottom *D* divides chambers *A* and *B*, and on this is placed a thick bed of coke *E*. The water enters at *F*, filters through the bed of coke and drains into the chamber *B*, and thence into the pump chamber *C*, from which it is drawn by the pump attached to the outlet pipe *G*. Any particles of coke or sand which may pass through the perforated bottom will collect in the chamber *B*, and cannot rise to the outlet *G*, thus preventing their getting into the pump.

It is true that frequent blowing off of a boiler will tend to prevent the deposit of heavy scale, since much of the precipitated matter will be ejected before it has had time to adhere and bake to a crust. Nevertheless, it is wise to guard against admitting the impurities at all, by using some means of separation outside the boiler; for there are some impurities which cannot be expelled by the use of the bottom blow-off. They are the lighter ones, which float as a scum at the surface of the water, and the most effective method of removing them is by the use of a surface blow-off or by a skimming device.

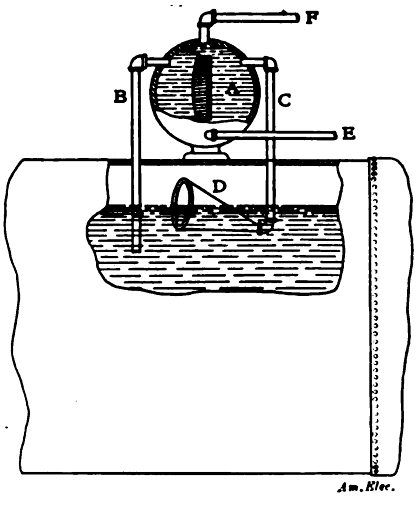

FIG. 3.

One form of skimmer is shown in Fig. 3. It consists of a spherical vessel *A* located above the boiler shell. A diaphragm divides the vessel into two chambers, into each of which leads a pipe, the pipe *B* connecting with the water space of the boiler and the pipe, *C*, connecting with a funnel-shaped casting, *D*, whose mouth is toward the front of the boiler. The diameter at the mouth is such that no matter how much the water level may vary within its usual limits there will always be some surface water in the funnel. Since the circulation in a return tubular boiler is from front to rear at the surface, the scum is carried into the funnel, and thence up the pipe *C* into the spherical vessel. Here the water is cooled and the sediment is deposited, after which it is blown out through the pipe *E*. The lighter scum, such as oil and the magnesia salts, rise to the upper side of the globe and are blown out through the pipe *F*. The purer feed-water then descends by the pipe, *B*, into the boiler. The circulation is continuous, and is maintained by reason of the fact that a column of cold water is heavier than a column of equal height composed of hot water and steam.

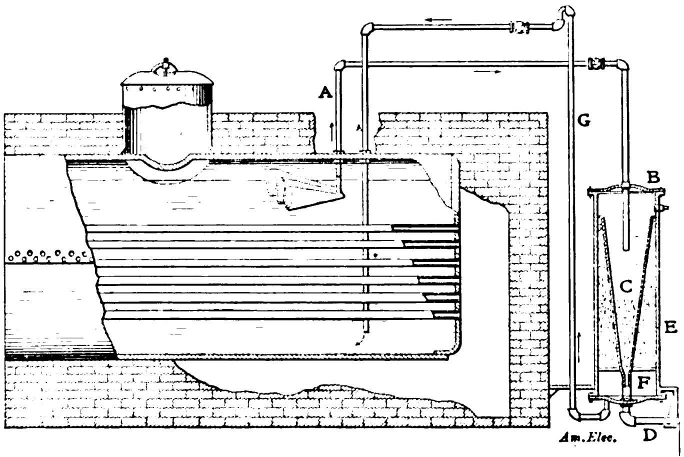

FIG. 4.

A mechanical cleaner of greater capacity and more elaborate construction is shown in section in Fig. 4. It has three funnels for gathering the sludge, and they are connected to a common discharge pipe, *A*, leading to the settling chamber *B*. The settling chamber is a vertical shell containing an inverted conical chamber *C* into which the scum and sludge are led by the pipe *A*. The lower end of this cone terminates in a blow-off pipe *D* through which the impurities that collect are blown out at frequent intervals. The water, after, being freed of its impurities in the chamber *C*, rises and flows over the upper edge of the cone, and then trickles downward through the bed of filtering material *E* surrounding the inverted cone. By the time it reaches the chamber *F* it is comparatively free from impurities, and it is then returned to the boiler by the steam loop *G*. The use of three funnels at the surface of the water gives greater opportunity for collection of scum. The action of this device, as well as that of the cleaner shown in Fig. 3, is continuous so long as the boiler is in operation, and the rapidity of flow may be regulated by a valve on the discharge pipe connected to the funnels.

The use of chemicals to purify boiler feed-water has reached enormous proportions during recent years, and there are a score or more of manufacturing concerns whose sole business is the preparation of boiler compounds. The usual procedure is to obtain samples of the feed-water and of the scale produced from it. These are analyzed quantitatively, and the exact amount of each impurity per gallon of water is found. Then a compound is prepared containing chemicals in such proportions as to just neutralize the evil effects of the impurities, or to change the latter into some other form which shall be harmless and easy to remove.

For example, suppose that a feed-water contains sulphate of lime and sulphate of magnesium. These would form a hard scale; but if carbonate of soda is added in correct amount, the sulphates are changed to the carbonates by the chemical action which takes place. So, instead of water containing sulphate of lime and carbonate of soda, there results carbonate of lime and sulphate of soda. Similarly the sodium carbonate changes the sulphate of magnesium to magnesium carbonate and itself becomes sodium sulphate. Now, the carbonates of lime and magnesium are insoluble in hot water, and consequently the former is precipitated to the bottom of the boiler, whence it may be blown out, while the latter floats and may be removed by a skimming device. The result of the chemical action has been simply to change a harmful salt into a harmless form. The sodium sulphate formed is readily soluble in the water, and hence is at once taken up, leaving no precipitation.

And thus it is with all purifying compounds. They act chemically upon the water so as to form new compounds which are harmless and easy of removal. But it should be borne in mind that for every different impurity a different style of treatment should be applied. It is just as absurd to suppose that one kind of boiler compound will cure all cases of scale formation as to expect one medicine to cure all bodily ills. And, finally, it must be remembered that a boiler compound does not destroy the impurity utterly. There will always be a residue which must be removed at intervals if the boiler is to remain efficient in its service. The advantage is that the sludge may be blown and flushed out, whereas scale would require chipping and knocking, with probably injury to the plates and tubes.

◆

The cost of electric power at Ilford, England, is, according to the city electrical engineer, 4.8 cents per kilowatt-hour sold. This is based on the last year's costs, and includes sinking fund and interest charges.

AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

Siding Protection.

It is important that where a long siding or crossing exists, that this siding be protected so that it resembles in itself a short section of track. An arrangement for accomplishing this protection is shown in Fig. 27. The crossover *b* is connected to a track battery and to the relay *a*. This relay has two armatures *e*, one of which is in series with the home signal line wire *c*, the other in series with the distant wire *d;* this relay thus protects against a train being across the crossover, which would not otherwise effect the signal.

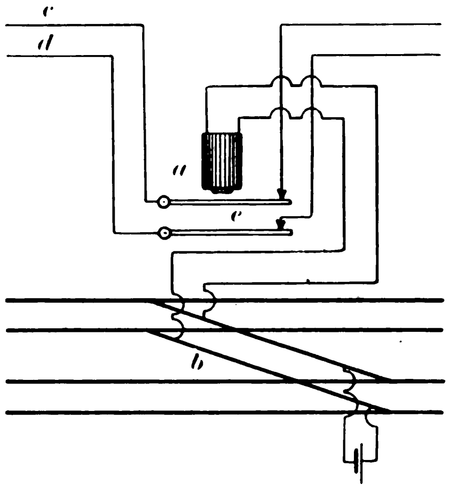

FIG. 27.

Crossing Signal Circuits.

Although railroad crossing signals are not usually considered in the same light as the automatic railroad signal, since they are automatic in their action, there exists but little difference between these and the railroad signal.

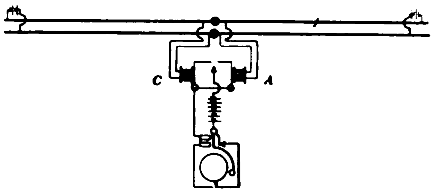

FIG. 28.

In Fig. 28 a simple crossing signal is shown, which announces, by the operation of a bell, the approach of trains, when within the limits of the block, in either direction. Connected to the two insulated sections, across the rails of which the difference of potential is maintained by the usual track batteries, are the relays *A* and *C*, which close the circuit of a bell. The bell and relay are stationed in a post placed at the

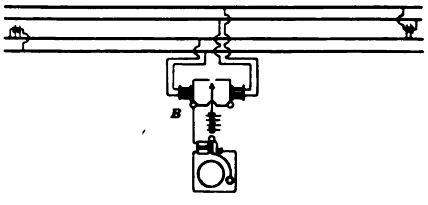

FIG. 29.

highway to be protected. When either track section is short circuited by the movement of a train, the armature of either relay causes the bell to be connected to the battery in the manner shown. The armatures of these relays are of a construction which

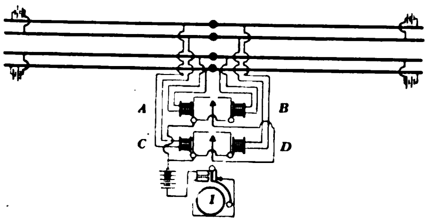

FIG. 30.

gives a contact with a scraping motion, as will be evident from the diagram.

The arrangement of a crossing signal for a double track system is shown at *B* in Fig. 29. This arrangement announces the approach of trains on either track in either direction; the connection, otherwise, being similar to that above described.

Another double track arrangement for

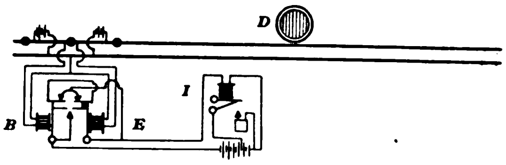

FIG. 31.

single track movements is shown in Fig. 30, four relays, *A, B, C* and *D*, being used in this case; these operating a bell *I*, through a battery common to all the relays. With the exception that four insulated cut sections with their batteries and relays are required, this system is similar to the above, giving, however, more reliable protection.

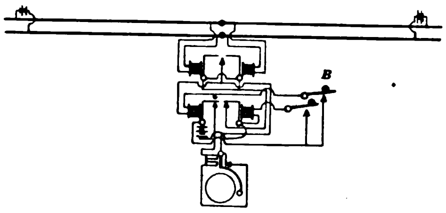

FIG. 32.

The circuit arrangement shown in Fig. 31 has two short, insulated rail plates, connected with batteries to the uninsulated rail and also to the relays *B* and *E*. These relays operate an indicator *I* in the tower *D*, thus warning the gateman in this tower of the approach of a train. This drop will, therefore, warn the tower attendant of all trains approaching the tower from the direction of the insulated section, but not the trains receding from the same.

In Fig. 32 an arrangement for manually stopping the bell while the train is on the track circuit is shown, this operation being performed by the keys *B*, which control the relays connected to the bell, operated by either track section. The bell, however, is automatically rearranged for the next operation.

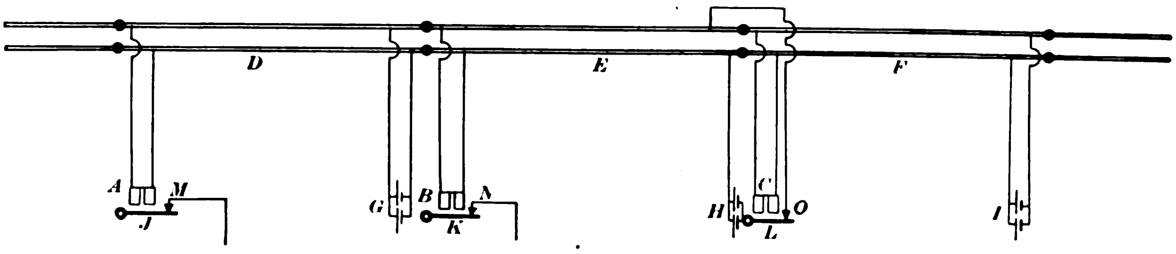

FIG. 37.

In Fig. 33 the same arrangement is shown with the exception that the train automatically starts the bell *A* when it has reached the section *D*, by the action of the relay at this point.

In Fig. 34 an open circuit system for the operation of a drop, *C*, at a signal tower is shown; otherwise, this installation is similar to that shown in Fig. 28.

Simple Signa Circuits.

In Fig. 35 two methods of normal clear signal control are shown. In the upper

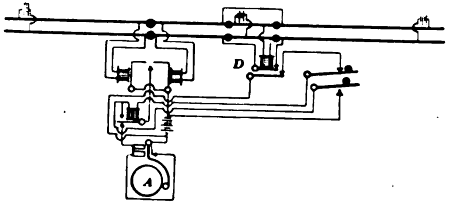

FIG. 33.

part of the figure, the entire cut section, with the relay *B* and track battery *E* is shown. This relay controls, through the battery *D*, the signal *A*, the relay *E* performing a similar function. With a train at section *C*, *A* will be held at danger, *E* being unaffected.

In the lower part of the engraving, overlap signals *H* and *J*, which are controlled by relays located at a single point, are shown. *H* is held at danger until a train has left the first block in the front of *J*, while *J* is held at danger by a train in the block between *J* and *H*. On account of its greater distance from the main battery, *H* is operated by a greater number of cells

In Fig. 36 the connection of signals, the circuits of which are mechanically operated, is shown. The signals *A* and *D* are controlled by the switch *C*. The arrangement of this signal is such that no signal can be thrown to the clear position without the other being held at the danger position. Indicators *E* and *B*, which in reality are miniature signals, show, by their indication, the condition of the signals. In the lower part of this figure the movement of the lever *F*, which is connected by mechanical means to a semaphore, closes or opens the circuit of a distantly located signal, thus apprising an approaching engineer of the position of the mechanically operated semaphore.

Track Circuit Controlling.

The relay method of signal control, which is used almost exclusively in systems which do not require line wires, is shown in Fig. 37. Connected to cut section *D, E* and *F* are the track batteries *G, H* and *I*. *G* operates the relay *A* and, therefore, controls the armature *J*, which makes contact with *M*. These latter are connected in series with the signal and its batteries. When *G*, therefore, is short circuited, the signal circuit will be open circuited.

The same arrangement is shown connect-

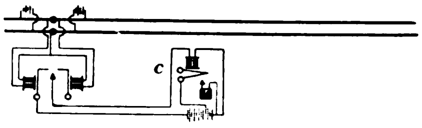

FIG. 34.

ed to cut section *E*, the relay *B* controlling a signal through the contacts *K* and *N*. The battery *H*, which operates the relay *B*, is connected in series with the armature *L* and the contact *O*, this armature being operated by the relay *C*, which receives current from the track battery *I*.

If *I* be short circuited, therefore, the armature of the relay *B* will drop, because the armature *L* falls, and thus open cir-

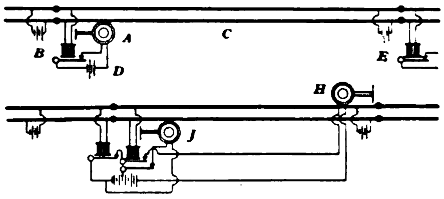

FIG. 35.

cuits the battery *H*, which creates a difference of potential across the cut section *E*. By such an arrangement, therefore, one relay may be controlled by another relay in another cut section.

Normal Clear Circuits.

In Fig. 38 a normal clear line wire system of home and distant signals on the same masts is shown. Two line wires *N* and *V* in this case are necessary. Five signals, *A*,

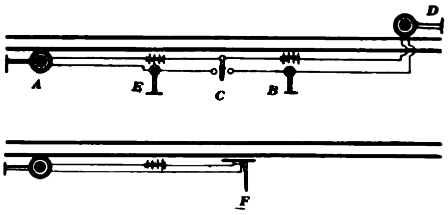

FIG. 36.

B, C, D and *E*, with their connections, are shown. A train is supposed to be across the track at *F*, thus holding the home board at *O* in the danger position and the distant board of signal *D* in the same position, the other signals being unaffected.

Describing the apparatus at *B*, which is common to all of these signals, there are: the circuit breakers *m* and *s*, operated by the home board of the signal; *m* open circuits the line wire *N*, while *s* open circuits the distant board.

The signal battery *n* is connected to one side of each board, and also to the home board through the armature of the relay *v*. This battery also gives current to the distant board of the first signal in the rear of *B*. The other connections will be readily seen from an inspection of the diagram.

In Fig. 39 the polarized or "wireless" method of normal clear control for home and distant signals on the same mast is shown. The signals *H, I, J, K* and *L* are operated by local wires and the rails of the track, which latter form the only circuits employed between the signals.

A train is supposed to be at the position *G*. Describing the accessories at signal *I* there is a polarized relay *w*, having the armatures *c* and *f* connected to the track section. On the other side of the insulating joints, the track battery *a* is connected, through the polarity changer *b*, operated by the home board of the signal, to the track section. The polarity of *a* controls the polarized relay at the signal *j*.

The signal battery *t* is connected to the home and distant boards of *I*, the other side of this battery being connected to the home board through the armature *c* and to the distant board through the armature *f*, and the circuit breaker, which latter is operated by the home board. Hence, when the home board is in the clear position, this circuit breaker is closed, and if the armature at *f* makes contact, current will pass through the distant board. The same arrangement is used at every signal.

In Fig. 40 a normal clear line wire signal system is shown with home and distant boards on separate masts; *A, C* and *E* are home boards and *B* and *D* distant boards. The switch *Y* is supposed to be open, thus short circuiting the track through the switch instrument *I*.

Signal *A* is shown in the clear position; battery *F* of this signal being connected to it through the track relay armature *J*; signal *B* receives battery current from *G*, through the armature *c* of the relay *V*; one side of the armature being connected to the common line wire, as is also one side of the battery *G*. A double relay, *a*, acts on the same armature, the lower of these being in series with the track battery, and the upper being energized when current passes through the signal. The former is connected in series with the armature *b* of the track relay *V*.

The track relay at signal *C* is provided with armatures *U, T* and *S*; *U* being in series with the switch instrument *R* and connects one side of the signal to the common wire, through this instrument. *T* is in series with one side of the signal *B* and also with the circuit breaker *Q*, operated by signal *C*. This circuit breaker connects one side of *C*, therefore, with one side of signal *B* through the line wire.

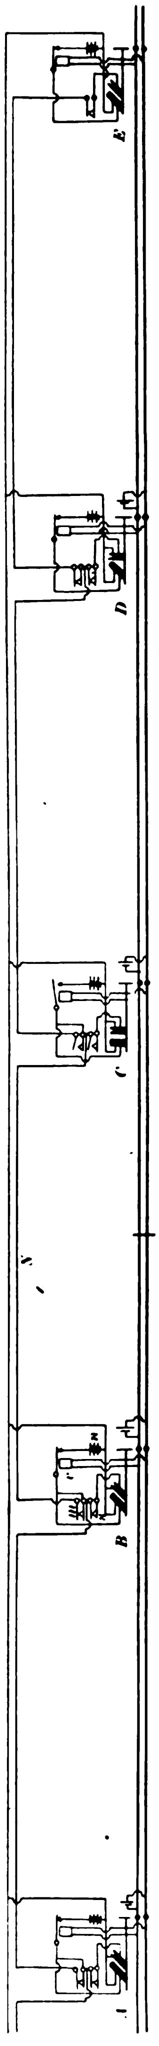

FIG. 38.

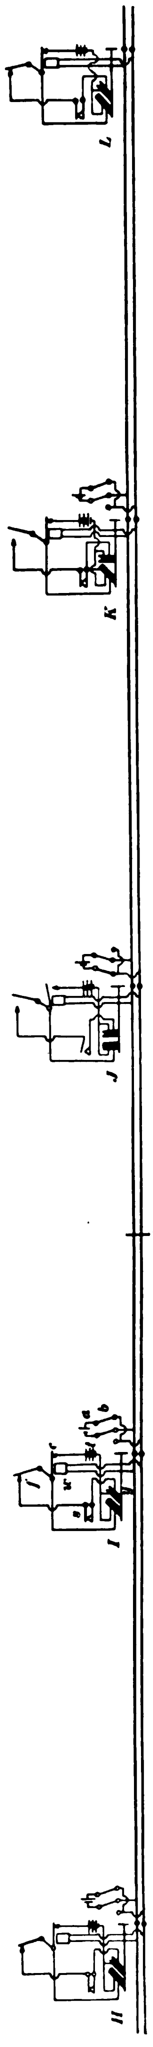

FIG. 39.

The armature *S* is in series with the armature *d*, and connects the switch instrument *P* with the battery *G* and the common line wire; when *S* and *d* are closed, therefore, the switch instrument *F* will be in the clear position. In the diagram, however, with the switch *Y* open, *F* is in the danger position, since the armature *S* breaks the circuit at this point; the armature *O* of the track relay and signal *D* connect the track battery to the track at this signal, the armature *N* connecting to one side of the signal battery through the circuit breaker at *E*, operated by the latter signal.

The track relay at this signal has two armatures, *L* and *M*, the former giving battery current to the signal *E*, and the latter connecting one side of this signal and the battery *H* with signal *D* through the armature *N*; therefore, with *N, M* and *L* in the upper position, both signals, *D* and *E*, will be held at clear.

The manner of connecting a line wire, normal clear system is shown in Fig. 41. Four signals, *A, B, C* and *D*, with their connections are given; the common line wire *Q* running the entire length of the track, and the others wire, *P*, depending in number and length upon the interconnections. In the home block of signal *A* a train or open switch is supposed to exist. The same condition of affairs exists in the home block of signal *D*. The switches *E, G* and *H* are provided with the switch indicator *O* and the switch instrument *F*. On the switch *E* the switch instrument also closes the circuit between the common and indicator wires. The signal batteries *L, K, I* and *J* are all connected on one side to the common line wire, and on the other side to the top armature of the track relays of the signal sections. Describing the accessories at signal *C*, which are common to all the other sections, there is the track relay *a*, which has three armatures, *p, f* and *o*; armature *p* connects one side of the battery *I* with the home mechanism *j*, which is in series with the relay *g*, having two armatures, *m* and *h*; *m* connects through the resistance *i* when the relay is energized, one side of the battery *I*, with the line wire, passing to the lower armature of a similar relay at signal *D*. When the home board at *C* moves to clear, the circuit closer *n* short circuits the relay *g*, thus allowing its armatures to drop. The lower armature *h* thereby sends current from the battery *I* into the switch indicator, *M* and *N*. The resistances *e* and *i* limit the current flowing through the circuits operated by the armatures *o* and *h*. The distant board mechanism *k* of the signal *C* is connected in series with the battery *I* through the armature *d*, the circuit closer *l* being operated by the home board and the instruments at the signal section *B*. The rest of the connections may be readily traced up from the diagram, it being similar to those we have already described.

In Fig. 42 a normal danger system with part track relay and part line wire method of control is shown. This constitutes what is known as an overlap system. Two signals, *A* and *B*—*A* having two sections as shown, 1 and 2, and *B* three sections, 5, 4 and 3—are given, together with an additional section, 6, to which is connected the relay controlling the battery current which operates the signal mechanism of *B*. Describing the apparatus at signal *A*, there is the track 1 connected in series with the contact *j* of the track relay *k* in section 2, and with the double functioned relay *e*, and also to the rails of the track of section 3. This relay, *e*, is known as a clearing relay. If a train be on section 4, the relay *o* will be short-circuited and thus open the circuit of the signal, *B*. The same action will occur if a train be on section 5. A train at section 4 will short-circuit the battery connections through the armature contact of *n*. This, however, does not affect *n*, for if a train be across section 3, the relay, *n*, will be short-circuited, thus causing its armature to drop and open-circuit the battery connected to section 4, and thus de-energize the relay, *o*, which drops its armature and open-circuits the battery of signal *B*. The clearing relay of the latter will close its contact, but the signal will remain at danger.

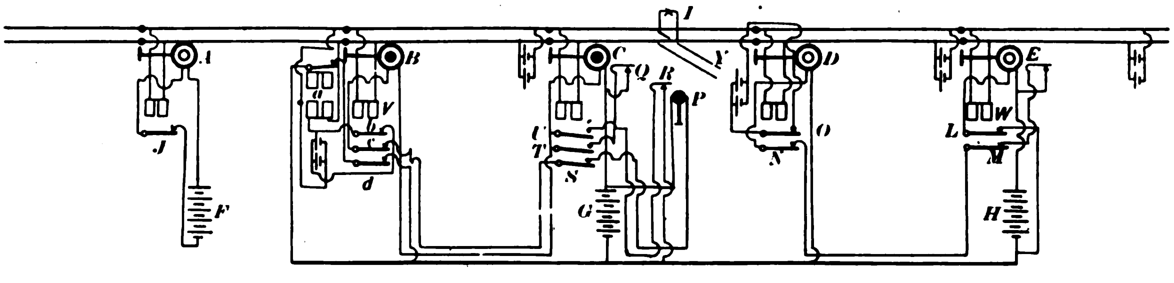

FIG. 40.

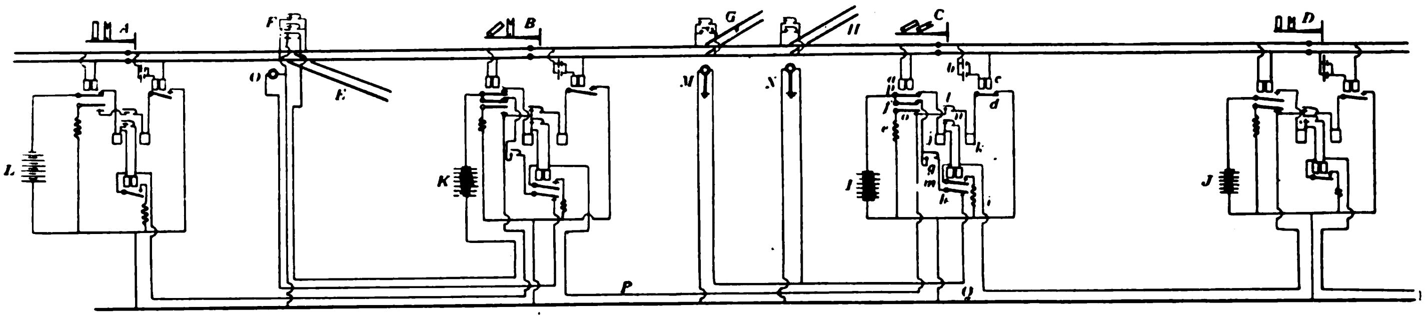

FIG. 41.

In Fig. 43 the arrangement of a normally clear circuit with the overlap method of signal control is shown. The track relay *q* connected to section 8, in the block of signal *C*, has two armatures, one of which is connected in series with the track battery of section 9, and the other, *u*, in series with the signal battery *t*. Sections 9 and 10 are controlled by the relay method. Section 12 is not connected through a clearing relay, as it is not necessary in this case. The relays connected to sections 10 and 11 have armatures which normally close the circuit of the signal battery and these hold *D* in the clear position.

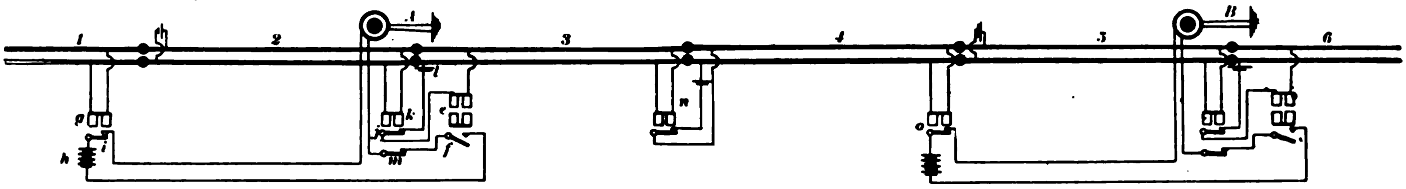

FIG. 42.

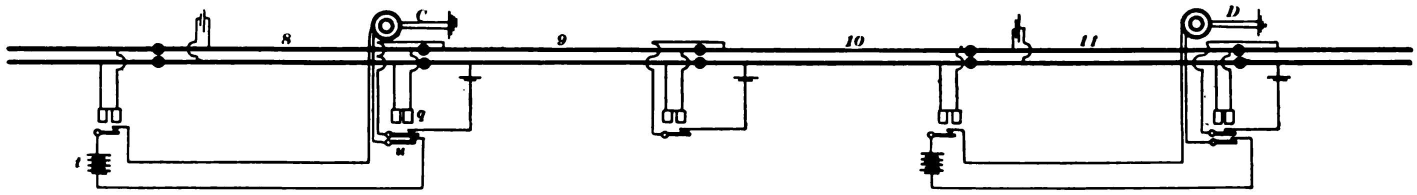

FIG. 43.

In Fig. 41 the resistances of the various relays at section *C* and of the similar relays at the other cut sections are as follows: *a*, 4 ohms; *c*, 16 ohms; *k*, 50 ohms; *j*, 50 ohms, and *g*, 200 ohms. The resistance *i* is equivalent to 75 ohms, and the resistance *e* to 50 ohms. All relays directly connected to the track have a resistance of 4 ohms, and all relays in series with the tracks and track battery 16 ohms. This applies to nearly all the relays in all of the various systems described or to be described.

In Fig. 44 the diagram of connections of the normally clear polarized relay system of home and distant signals on separate masts with overlap is shown. A train, *c*, is supposed to be across the section 6, controlled by signals *A*, *E*, *D* and *F*. Each signal protects one of the sections 1, 2, 3, etc. At the home signals, *C*, *E*, *G* and *I*, the current reversers, *a*, operated by these boards and connected to the track, are shown. On each of the distant, or fish-tail signals, *B*, *D*, *F* and *H*, are shown polarized relays, *d*, which effect the connections in a manner which will be evident from an inspection of the diagram. Since a train is in section 6, the neutral, or current, armature of *d* short circuits the track battery of section 5, and thus holds signal *E* at danger, by depriving the relay at this point of current. The movement of the semaphore at *E* reverses the circuit in the track section 4, and, by moving the polarized armature at the sign *D*, holds the latter at danger by open circuiting its battery.

In Fig. 45 the line method of controlling these overlap signals is shown, a train in this case being at section *e*. The home signal *J* is controlled by the relay at this point which derives current from the battery at signal *K*, line wires connecting the signals *K* and *L*. When the latter signal is in the clear position the circuit is closed at *n*, which thus connects the signal battery at *L* with the latter. The distant signal *O* being at danger, the relay at this point has its armature in the lower position, thus short circuiting the track battery at *L*, and holding the latter in the danger position.

The same means also hold *M* in the caution position. The same connections are used at signals *P*, *Q* and *R*, the two armatures of the relay *f* in this case being in the upper position, and holding both of the signals, *P* and *Q*, in the clear position.

In Fig. 46 a diagram of the circuits employed in the relay method of polarity control is shown. The relay 1 controls the signal *S* through the relay at the latter point. The current reverser *g*, connected to the track through the armatures of the relay at this point, controls the movement of the relay at signal *T*. The relay at *g* is con-

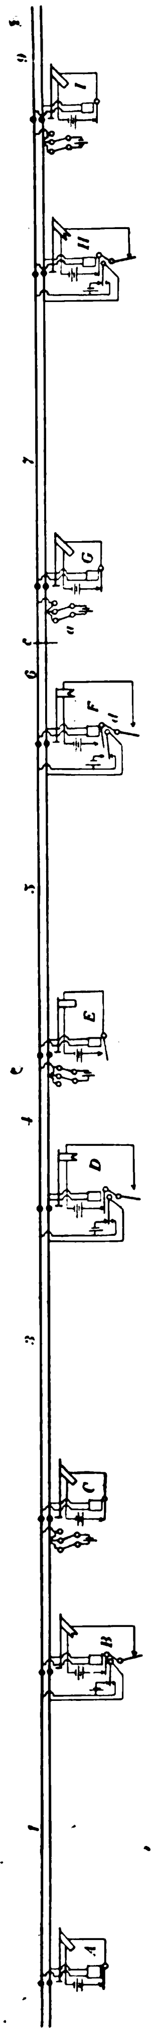

FIG. 44.

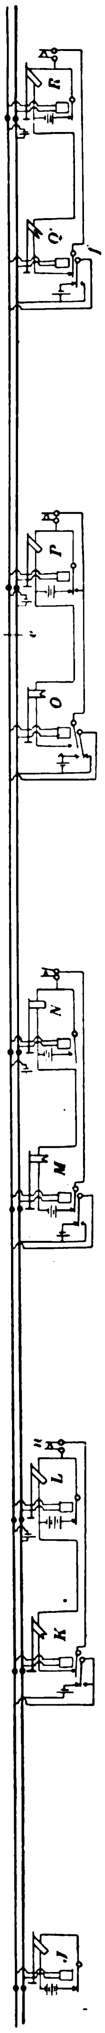

FIG. 45.

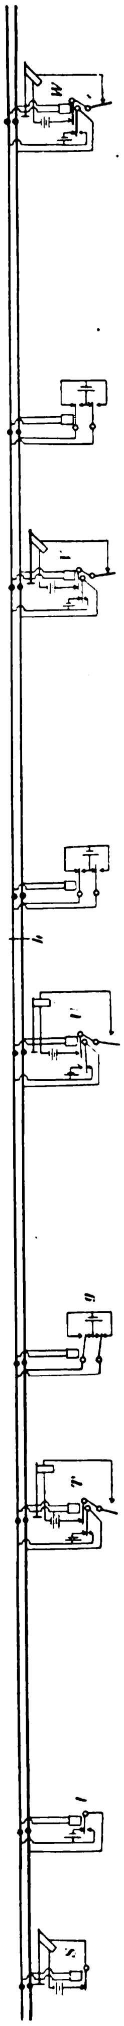

FIG. 46.

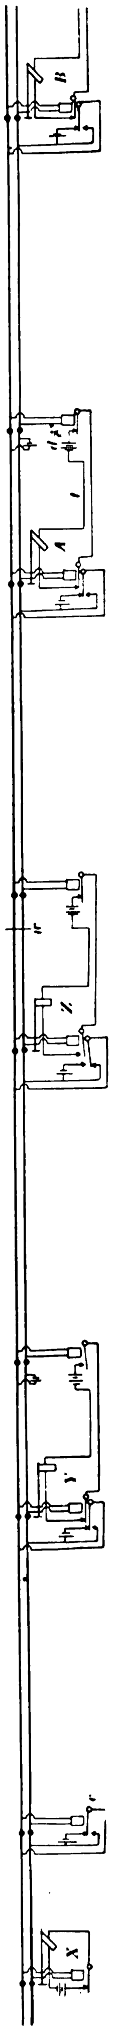

FIG. 47.

trolled by the polarized relay at *U*, which in this case holds this signal in the danger position by having its neutral armature in the lower position, caused by this relay being short-circuited. Signals *V* and *W* are in the clear position for obvious reasons.

In Fig. 47 the circuit arrangement of a normal clear signal, controlled partly by the track circuit and partly by the line wire system, is shown. This system is also an arrangement for overlap signals. A train at *w* holds *Z* at danger, the relay at the latter being short-circuited, which also short-circuits the relay controlling signal *Y*. The signal *A*, and also the signals *Y* and *Z*, have two wires running to the first section which they protect. These line wires, shown at *t*, cover approximately one-fourth of the entire track distance.

In Fig. 48 the arrangement of a normal clear system of home and distant boards on the same mast is shown. The track contains two switches, *E* and *X*, a train being supposed to be in the block protected by the signal, *C*.

It would seem that, since this train is only in the home block of the signal, only the home board should be held at danger; but all double-indication, or double-block signals, have an arrangement of circuit connections such that the distant board is always at the caution position when the home board is at the danger position.

The circuit of the distant board has in series a circuit-closer controlled by the home board. It is in this manner that the distant board assumes the caution position whenever the home board is at danger.

The track relay, *V*, at the signal, *A*, has two normally closed armature contacts, one of which is in series with the home signal magnet, *Q*, and the other in series with the signal magnet, *J*. *J* connects with the common line wire and *Q* with one side of the main battery. The double relay, *Z*, has its lower magnets in series with the track battery and the upper magnets across this track battery, so that both are connected virtually in series with the track battery.

When a train is on the track, the upper magnets are short circuited and the lower fully energized. The armature of this latter relay is connected through the line wire to the switch indicator *I*, causing the latter to assume the clear position when the armature is in the position shown, by connecting this instrument to the common line wire through the signal battery.

The purpose of the switch instrument at the switch *X* is evident from the diagram. The relay *L* has four armatures, which are connected so as to energize the signal magnets when in their upper position, the distant signal magnet being controlled through the circuit closer, operated by the home board of the signal *B*. The second armature of this relay connects, through the line wire *W*, to the lower armature of the relay *K*, thus connecting the battery at signal *C* with the distant board at signal *B*.

The signal magnets *R* and *S* of this signal are connected in a manner similar to that at the signal *B*, the circuit closers *O* and *T* in this case being open, due to the position of the disks at signal *C*. At *D* a home signal only is shown; the track relay *N* being provided, in this case, with three contact armatures, the upper of which, *P*, controls the signal magnet, the contact of the compound track relay *M* controlling the indication of the switch instrument *H*. The switch instrument at *E* is provided with short circuiting contacts *F* and also with the circuit closer *G* connected to the common and indication lines wires.

A diagram of the means employed in electric locking is given in Fig. 49. The relays 1, 2, 3 and 4, with the contact carrying armatures, *a*, control the current passing through relay 8. When 8 is energized, its armature *d* causes the energizing current from battery *e* to continue to pass through it, if the circuit closers at *C* are not open, which will not be the case if any conflicting routes are set up.

If any of the relays, 1, 2, 3 and 4, are short circuited, or de-energized by open circuiting, *d* will still be held in its upper position, but the slot, or indicator, relays, 5, 6 and 7, will be de-energized, thus allowing their armatures *b* to drop and lock the conflicting routes, or else give indication of such confliction.

The Union method of signal control is shown diagrammatically in Fig. 50. This figure shows the connections of the various accessories of the signal *AB*, which has both distant and home boards, an explanation of the operation of the latter only being given in this description. The home board protects the signal block on the rear of the insulating joints *U*, section *X* (along which a train is supposed to be passing) forming part of the block protected by the signal immediately preceding the signal *A*. The connection of the relay *Q*, however, is supposed to be at the end of this latter block.

This relay is of the polarized type, and has two armatures, *X* and *S*. The former is known as the polarized armature, the direction of its movement depending on the polarity of the current passing through

Q and the movement of the armature *S* being controlled by the continuation of cessation of current through its coils. All the apparatus, except that connected directly to the signal *AB*, is located at the signal immediately preceding *A*.

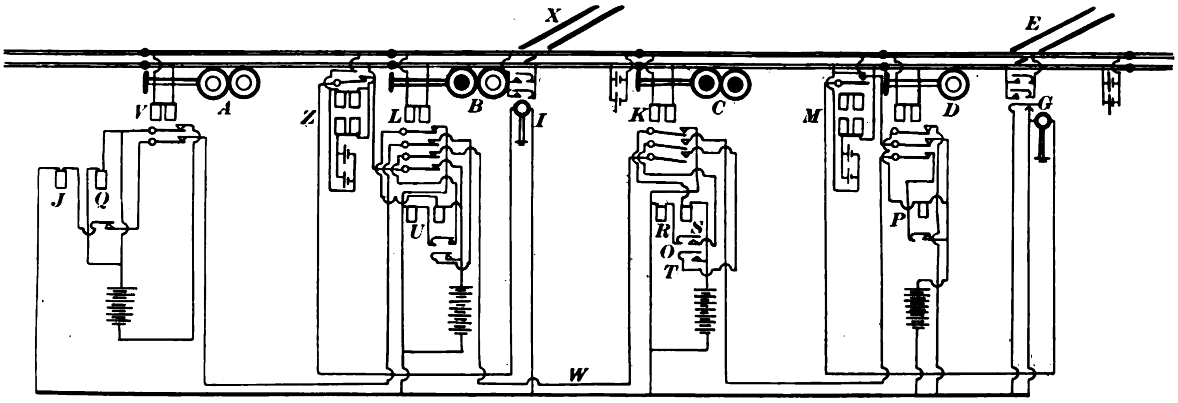

FIG. 48.

This apparatus consists essentially of the motor *E*, placed at the base of the signal, the signal battery *G*, operating the signal, the slow releasing relay *I*, the track relay *Q*, and the slot magnets *K* and *L*.

Suppose that the train passes the signal *A;* this will cause the home arm to move to the danger position, and reverse the polarity of the track battery *C*, connected to this end of the block *X*.

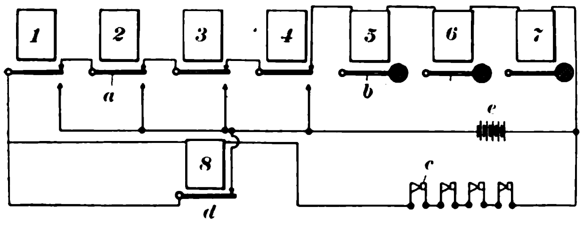

FIG. 49.

This is effected as shown diagrammatically through the rod *F* and the current reverser *D*. As soon as the train has passed out of the block *X*, the neutral armature *S* is raised by the relay *Q*, thus making contact. This connects one side of the battery *G* with one side of the slow releasing relay *S*, thus sending a current from the other side of the battery through this relay. This causes the armature *H*, pivoted at *T*, to make contact with *P*, thus connecting one side of the battery to the binding post 1, the other side of the battery being connected to binding post 3.

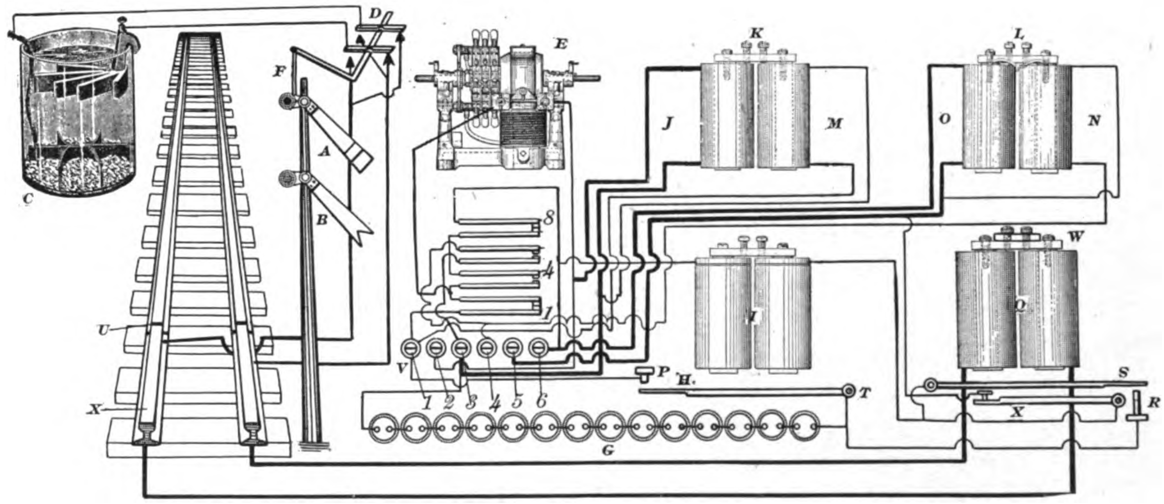

FIG. 50.

The contacts 1 to 8 are operated as follows: 1 and 2 are closed when the home signal of this signal moves to danger; 3 and 4 are opened, 5 and 6 being also opened, while 7 and 8 are closed by the operation of the distant signal.

The signal slot magnets *K* and *L*, the former on the home signal and the latter on the distant signal, have each two windings, one of high resistance and the other of low resistanhce. The reason for these two windings is as follows: Since a small number of cells of battery for each signal are used, and owing to the low voltage of each cell, the signal motors are of a very low resistance, and require a very heavy current for their operation, especially at the start, when the counter voltage of the motor is very low. This heavy current discharge causes the battery voltage to drop considerably, which decreases in a very marked manner the current energizing the slot magnets.

It is for this reason that they are compound wound, the series winding carrying the heavy current taken by the motor, thus giving the magnets a high degree of magnetization. This renders unnecessary a separate battery for slot magnet operation.

The slot magnets are normally continually taking current when the signal is in the clear position through the high resistance winding.

The purpose of the slow release magnet *I* is as follows: When the polar armature of the track relay is shifted by the reversal of track circuit, the neutral arm releases and almost immediately returns. The home signal is controlled through the armature of this relay *I*, which has a very high self-induction and thus prevents the immediate release of its armature.

Motor *E* is connected to the second binding post and also to the first, through contacts 1 and 2 operated by the home board. This motor thus derives current through the armature *H* of the relay *I* and through the lower resistance winding of the slot magnet *K*. The rest of the circuit relations may be readily traced up through the diagram.

◆

Extensive Electric Traction—The New York, New Haven & Hartford Railroad Company has begun work on its new proposed six-track electric rapid transit system from New Rochelle to the Harlem River. Property has been purchased east of the tracks at New Rochelle, where a station will be erected. Already the work of constructing a subway under the tracks has been begun. A corps of engineers, surveyors and contractors who will be in charge of the work have opened offices at New Rochelle.

THE LAY-OUT AND CONSTRUCTION OF A MODERN SUB-STATION

BY S. O. SWENSON.

In modern central station systems distributing electricity for light and power purposes in large cities, the sub-station plays a prominent part. It has made possible the economical generating of electricity in large power stations from which current is transmitted at a high potential and converted, in the sub-station, to a lower potential suitable for light and power work.

The design of the Ohio Street sub-station of the Chicago Edison Co., which has been made the subject of this article, may be considered as a recent solution where real estate is provided, and where provision for extensive future growth is made.

This sub-station feeds the mains of an Edison three-wire system, interconnected from one end of the city to the other, and is laid out for four 1000-kw. rotary converter outfits, which include four 1100-kw., three-phase, air-blast transformers; four 88-kw., air-blast regulators, and four 1000-kw., 250-volt, rotary converters, with the necessary high and low-tension switches; one 1428-ampere, 70-volt, three-unit booster set, and a storage battery consisting of 150 type "H" tanks, each containing 49 "H" plates, with the necessary switchboards and auxiliary apparatus. The storage battery was manufactured by the Electric Storage Battery Company, and has a rating of 960 amperes for 8 hours and 3840 amperes for one hour.

The lot is 50 ft. wide by 100 ft. deep, located in the middle of a block in a manufacturing district about a quarter of a mile from the present electrical center of distribution. It is expected that during the next year or two a large power load will be con-

tracted for in the surrounding district, thus bringing the electrical center of distribution nearer to the sub-station. The property being in a manufacturing district, the cost is high, and so from a commercial standpoint it should be made a paying investment as well as the sub-station itself.

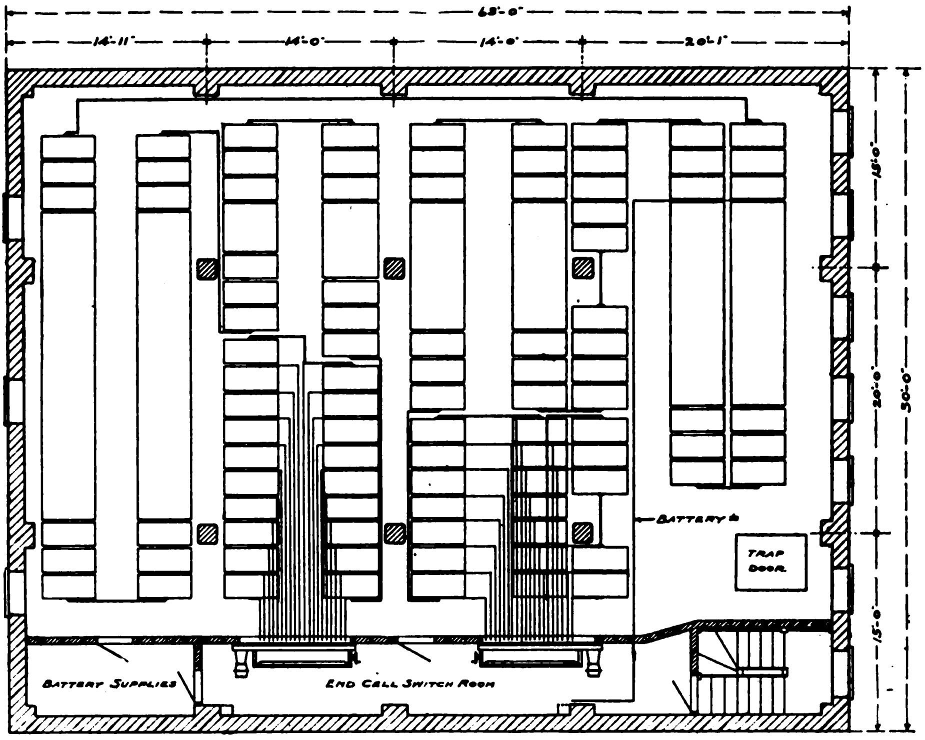

FIG. 3.—GENERAL PLAN OF THE BATTERY ROOM.

In order to minimize the present investment in building and at the same time allow the greatest possible latitude for the design of the ultimate building, it was decided to locate the present portion on the rear of the lot, as shown in Fig. 12, which was taken from the alley side and shows several of the large manufacturing buildings in the background. It it thus possible to erect such a structure on the front of the lot as future conditions may warrant and at the same time reduce the unproductive investment for the present.

The foundations and steel construction of the sub-station are sufficiently heavy for an eight-story building, the plans for the future being to build toward the street and upward. That portion in front of the sub-station might be used by the company for the installation of the fifth 1000-kw. rotary outfit, a high-tension switching center, customers' supply room and a main entrance to building, while the upper floors can be rented for manufacturing purposes.

Fig. 1 shows the general plan of basement, with future extension of building shown dotted; location of cable runs, feeder manholes, field rheostats, starting resistances, high-tension bus and air chamber, toilet room and drainage system. Fig. 2 shows the general plan of rotary converter floor, with center line dimensions of apparatus, and outside dimensions of building. Fig. 3 shows a general plan of battery floor, location of tanks, end cell switches and series and end cell copper connections. Fig. 4 shows a section through the building, looking north, and gives the general arrangement of the sub-station with copper connections and cable runs.

Referring to Fig. 4, it will be seen that the battery room is on the second floor and hence requires very heavy steel construction to sustain the load which is approximately 200 lbs. per sq. ft. for the entire area of the battery room. By having the battery room on the second floor the basement is free for all cable runs, high-tension bus and air chamber, mounting field rheostats, starting resistances, a heating system and a well-designed drainage system which would be impracticable were the battery in the basement as is often the practice.

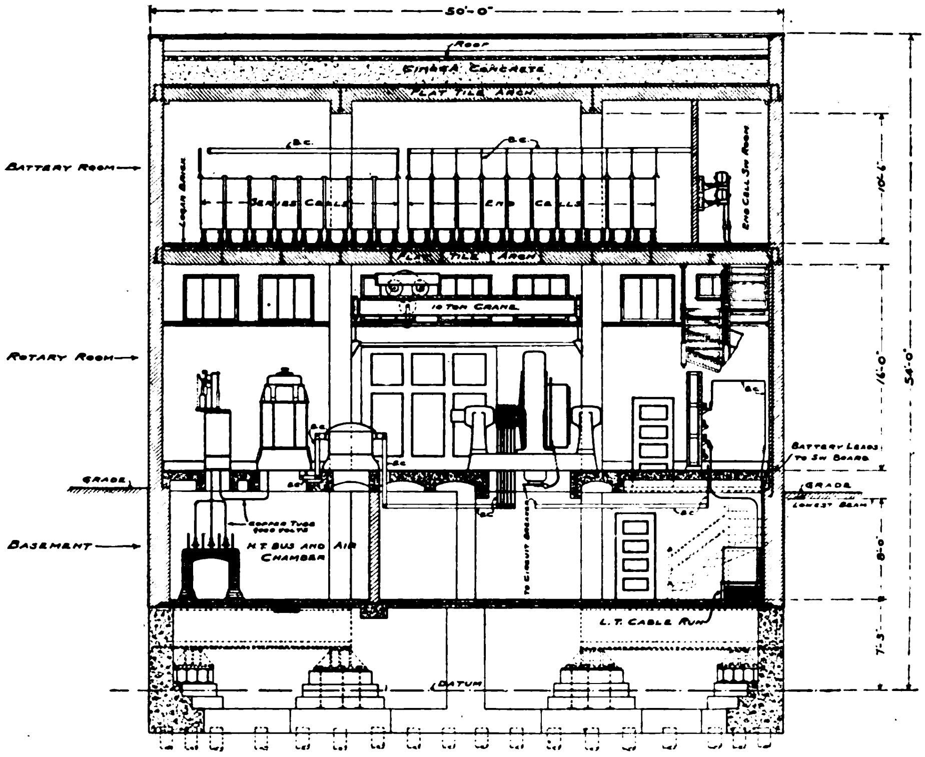

FIG. 4.—SECTION THROUGH SUB-STATION BUILDING.

It will also be noted that starting with the high-tension bus bars, which are two bars of 1½ in. by ⅜ in. copper, copper tubes are used as conductors to the oil circuit breaker, and also to the primary terminals of the transformers. These high-tension conductors are insulated with oiled linen and asbestos tape, the bus bars in addition being wrapped with cord.

From the secondary terminals of the transformer bar copper is used to the regulator and also from the regulator to the rotary converter and from the rotary converter to the direct-current switchboard, hence the only cables which are installed are the incoming high-tension lines, the battery cables from the end cell switches to the direct-current switchboard and the outgoing feeders. Further, it will be noted that the end cell switches are directly over the direct-current switchboard, thus requiring only a short run of battery cables.

Fig. 8 shows the relative location of the rotary converter outfit and direct-current switchboard. In the foreground a railing is built around the floor opening for a future machine; the crane shown is of ten tons capacity, hand operated; the brick compartment oil switch shown on the extreme right is the 9000-volt oil circuit-breaker for this unit. Approximately 6 ft. clearance is left between the rotary converter and the regulator which gives a liberal aisle the entire length of the sub-station and allows any part of a converter or transformer to be carried by a crane beyond units already installed.

One of the points requiring consideration in laying out a sub-station is the lighting. The circuits should be run in iron conduit and the number of lights for the rotary room and basement should be such as to give good general illumination, with plenty of wall outlets for extension cord lamps or light power circuits in case of emergency. In the battery room, however, more lights should be provided than is usually the case and these should be arranged so that they come in the center of aisles and on sufficiently close centers, to allow a thermometer or hydrometer to be read in each tank without using a drop lamp.

Fig. 5 which shows the high-tension lines for the entire Edison and Commonwealth systems in Chicago, indicates a method frequently used for providing two or more separate lines from the high-tension transmission system for each sub-station, i. e., either by a direct line or by a tie line which gives it a back feed through some other sub-station. The high-tension lines are protected by three overload relays, which are operated by series transformers on each phase of the line and are set to operate at a certain overload depending upon the location of the sub-station with respect to other sub-stations fed by the same line. The relays in turn close a tripping circuit on the control switch which operates the line oil circuit-breaker.

In case of trouble on the alternating-current side between the rotary oil circuit-breaker and the rotary converter there would be two direct feeds to the trouble; one from the high-tension line or lines, the other from the rotary converter. Should trouble develop, the direct-current system and battery, which floats on the system, would feed back through the converter and hence give alternating-current energy to the short.

The line or lines would be cut off at a certain predetermined overload. The machine would be cut off at 20 per cent reverse current, since the ammeter needles on the positive and negative sides of the rotary leads are equipped with platinum tips which close a circuit through relays which in turn close a circuit through the direct-current circuit-breaker and thus cut the machine free from the direct-current system. The rotary converter is also equipped with a mechanical speed limit device which closes a circuit through the circuit-breakers at 25 per cent excess of normal speed.

FIG. 5.—9000-VOLT LINES OF THE CHICAGO EDISON AND COMMONWEALTH ELECTRIC LINES.

The general diagram of connections for the complete installation of five 1000-kw. rotary converters is shown in Fig. 6. Starting with the high-tension bus bars there are two direct lines and one tie line to another sub-station, which would be used ordinarily as a feed to the other sub-station, but in case of trouble, on either of the other two lines, would be used as a back feed. The high-tension bus tie switch should be provided with some form of interlocking device so that the operator cannot get the closing circuit for the oil circuit-breaker until he has tested for synchronism.

The primaries of the transformer are delta connected and the secondaries diametrically. The neutral tap of the secondary winding is tied to the neutral of the direct-current system and thus providing a path for the unbalanced load.

FIG. 6.—GENERAL DIAGRAM OF CONNECTIONS FOR ROTARY CONVERTERS.

The regulator shown is an 88-kw. induction regulator by means of which the direct-current voltage can be raised or lowered approximately 10 per cent.

As shown in Fig. 8 and also in the view taken underneath the converter (Fig. 9), the direct-current circuit-breakers are mounted on the alternating-current end of the machines. This end was selected because all the free space on the direct-current end is needed for the proper attention of brushes and commutator. The view taken underneath the converter also shows the opening through the floor and the copper connections at machine. The copper connections shown in the center of the right side of the engraving, come from the regulator and tie to the alternating-current terminals of machine. The copper connections from terminal blocks on either side are shown going up to circuit-breakers and thence to the direct-current switchboard. The cables tie from the collector rings to the terminal blocks.

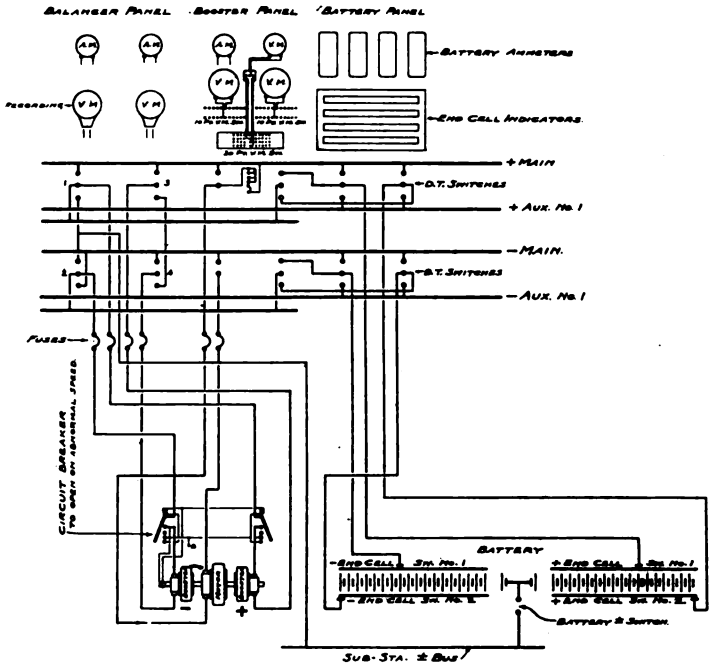

FIG. 7.—GENERAL DIAGRAM OF BATTERY AND BOOSTER CONNECTIONS.

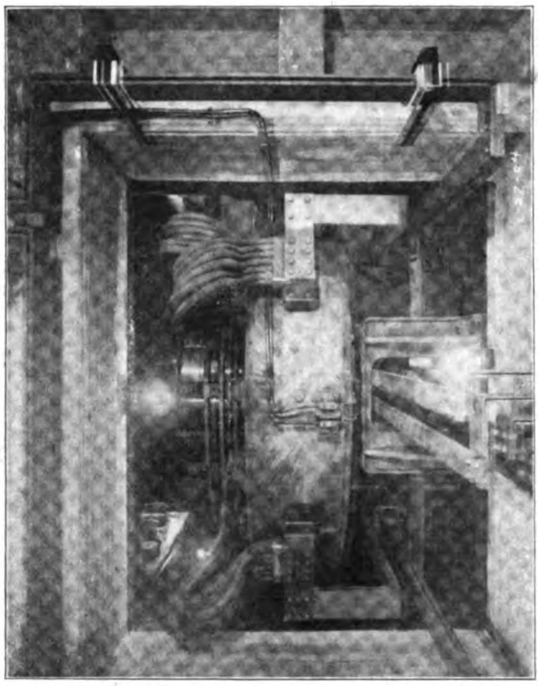

FIG. 9.—VIEW FROM BELOW ROTARY CONVERTER.

The direct-current switchboard is shown on the left side of Fig. 8; the panels from left to right being as follows: Feeder panels, balancer, booster, battery panels, rotary panels and station panel. Each feeder panel is arranged for four feeders, each feeder having one + ammeter, one — ammeter, one single-pole, double throw positive switch and one single-pole, double-throw negative switch arranged one above the other. The rotary panel is equipped as follows: One power factor indicator, one integrating wattmeter, one positive direct-current ammeter, one negative direct-current ammeter, two reverse current relays, one synchronizing switch, one regulator control switch, one oil circuit-breaker control switch with pilot lamps, which are connected to show green when oil circuit-breaker is open, and red when closed, two 2500-ampere switches, in parallel on positive side and the same for the negative side of rotary direct-current leads, starting switch with fuse extension in series with main starting switch and field switches with carbon break and discharge clips. The station panel contains a Lincoln synchronizer, alternating-current voltmeter and point switch, control switches with pilot lamps for line and bus tie oil circuit-breakers and main starting switches. The tie panel contains the potential indicators for recording bus and feeder pressures and the bus bar tie switches. The balancer, booster and battery panels are equipped as shown in Fig. 7, which shows the general diagram of connections for the battery installation. The end cells are equipped with two end cell switches on each side of the battery, hence can be charged and discharged simultaneously or discharged on two sets of bus bars at different potentials at the same time.

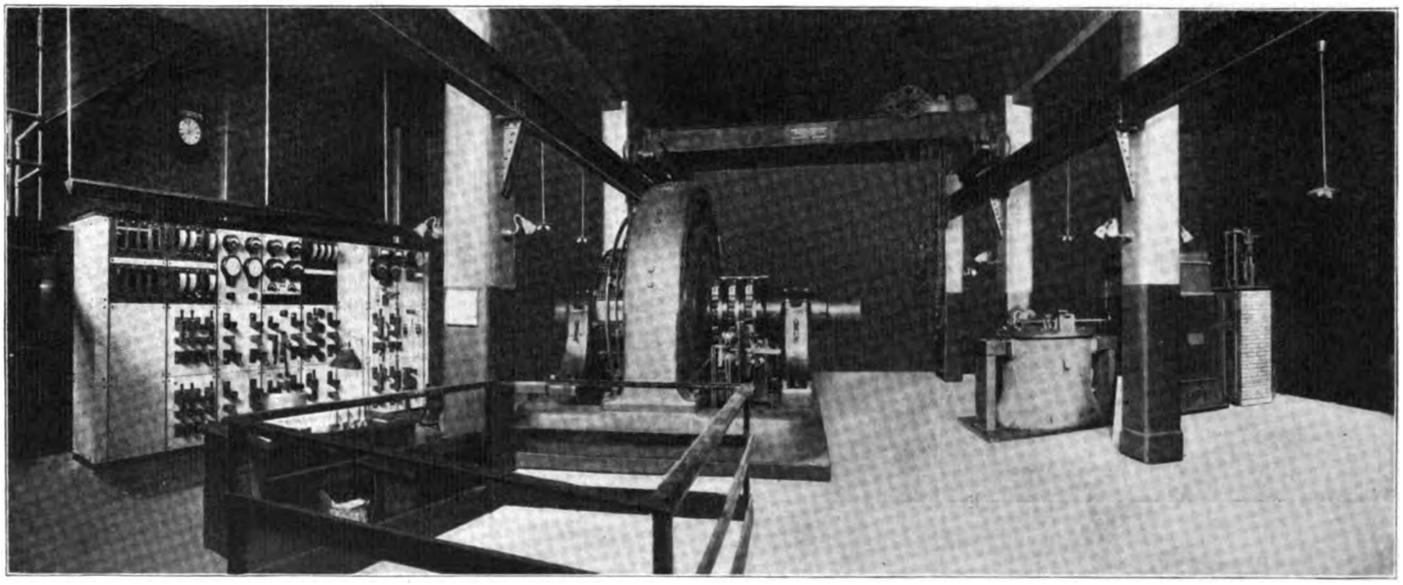

FIG. 8.—VIEW OF CONVERTER ROOM IN OHIO STREET SUB-STATION.

In order to indicate the position of each end cell switch at any time an annunciator system was installed, one annunciator drop being provided for each position of each end cell switch, thus doing away with the complicated system of gearing which was previously used with mechanical indicator.

The general arrangement of the bus bars, outgoing feeders, copper connections and space between switchboard marble and iron frame is shown in Fig. 10, taken from the rear of the switchboard. The marble is spaced 6½ in. from the iron frame by means of cast-iron spacers, the space being used for pressure busses, starting bus, discharge bus and any small conductors which cross the panels.

The arrangement of busses is as follows: At the top is the + main; next is the + auxiliary No. 1; next is the — main and at the bottom is the — auxiliary No. 1. Auxiliary bus No. 2 is not installed at present, but will be installed on the same brackets as auxiliary No. 1, being in back of same, with proper clearance; hence to change any feeder, battery or rotary from auxiliary bus No. 1 to auxiliary bus No. 2 merely means a longer tie from the switch stud to bus bars.

The switches are so arranged that the positive switches are on the top row and negative on the bottom and are so connected that when they are thrown up they tie to the main bus and when thrown down, to auxiliary No. 1 or auxiliary No. 2, depending upon the tie which is installed; thus with the three sets of bus bars three potentials can be maintained for feeders which can be fed as follows: Main bus entire capacity of sub-station, auxiliary bus No. 1 storage battery and three converters, auxiliary bus No. 2 two converters.

As there are no means of balancing the load, the three-unit booster set is connected so that the unbalance on either side of the system can be taken care of. This is done in the following way: To balance on the positive side close switches No. 1 and No. 2 up, No. 3 and No. 4 down, as shown in Fig. 7, and to balance on the negative side close switches Nos. 1, 2, 3 and 4 down. As the high-tension bus bars are installed in the basement it is very important to keep the basement dry and in order to prevent seepage of water into the basement a damp course was laid in the basement floor and through foundation walls consisting of three layers of tarred roofing felt. The foundation walls from the damp course to grade are cemented and tarred; as a further protection sub-soil drains are laid beneath the basement floor to carry off any surface water which may accumulate.

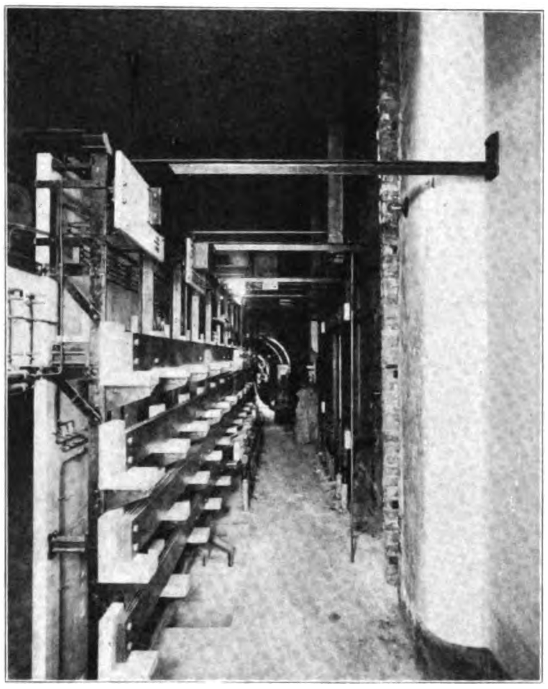

FIG. 10.—REAR VIEW OF SWITCHBOARD.

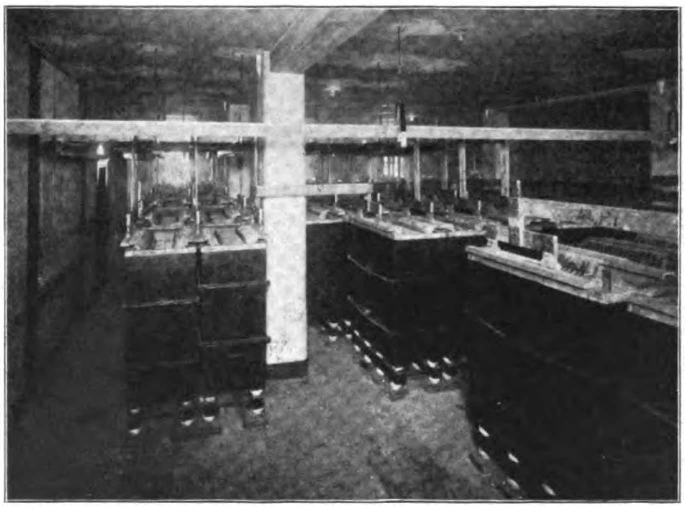

FIG. 11.—STORAGE BATTERY ROOM.

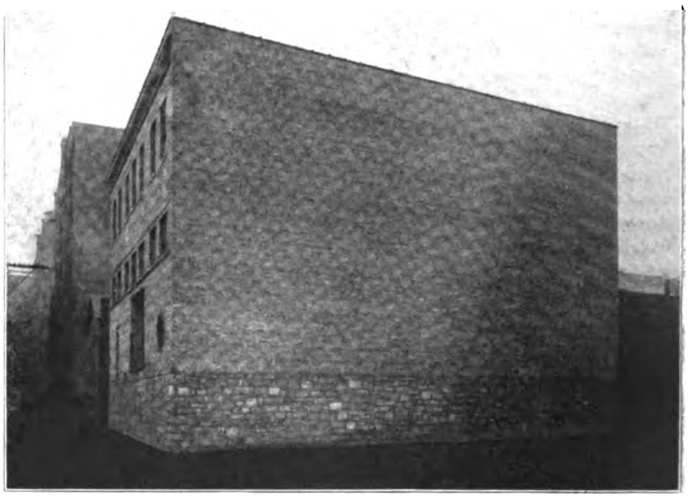

FIG. 12.—EXTERIOR VIEW OF SUB-STATION.

In order to prevent danger of back water from street sewer a check valve is placed in the building between two gate valves which are installed so that, in case the back-water valve fails to close, the sewer can be cut off and the back-water valve repaired.

Where it is advisable, depending upon the location of sub-station and general conditions, to spend more money on the finish of the building, the floor of the rotary room should be some form of encaustic tile or other non-absorbent material; but where it is not deemed expedient to have a tile floor, cement floors have proven very satisfactory, provided the cement is carefully laid and troweled down to a smooth, hard finish and lined off into squares in order to prevent unsightly cracks.

The framing for the rotary room floor should be laid out so as to give an opening under each machine of suitable dimensions for giving the machine a maximum natural ventilation and hence increasing its capacity. An opening to the outside should be provided for the blower intake which should be constructed so as to have two dampers, one to close the outside opening and the other to close the opening to the sub-station; hence, it is possible to take any proportion of air from outside and inside, depending upon the condition of the atmosphere in the sub-station and outdoors.

The view of the battery room, Fig. 11, shows the arrangement of tanks and copper connections. It will be noted that the tanks are supported by a double tier of insulators; this precaution was found necessary due to leakage from tanks to ground. The double row of insulators have proven very effective and afford more space for cleaning and inspection. All supports and copper connections are lead-coated and as an additional protection against the acid fumes, are covered on top with sheet lead. The battery room floor is made of Logan brick, which is a vitrified, hard-burned brick with all sides thoroughly glazed. It might not be amiss to add here a few notes on battery rooms in general.

In a number of battery rooms recently installed the floor construction is as follows: First, a layer of concrete is laid over a tile arch and floor beams and given a cement finish, which, when dry, is thoroughly mopped with hot asphaltum; the bricks are then laid with about 1-16-in joints, which are filled with hot asphaltum, thus making an acid-proof floor.

A cement base is provided on all walls and columns are protected by a lead base, all joints of which are burned; the top being turned into the fire-proofing around the columns and the bottom flashed underneath the hard-burned vitrified Logan brick floor.

All plastering in the battery room should be either of adamant or Portland cement, as the acid fumes have an injurious effect upon ordinary lime plaster and soon cause it to flake off. Even where adamant or cement plaster is used it has been found advisable to thoroughly paint it with white lead and oil as a protection against acid fumes.

Provision should be made for sufficient ventilation to carry away the gases given off by the battery during period of charge. In many cases this can be accomplished by installing suitable vents with intakes near the ceiling or in some cases by having ample window space.

Some means should also be provided for heating the battery room either by a heating system or by exhausting the hot air from the rotary room into the battery room. The temperature of the battery room should be kept at not less than 70° F., during the coldest weather, as the capacity of the battery varies materially with the temperature.

The building should be designed so as to conform with insurance regulations in order to obtain the best rate of insurance on building and contents, which is an important item on the fixed charges of a sub-station. In the gradual development of central stations from year to year, it frequently becomes necessary to design and build substations on lots varying from 20 to 50 feet in width. In some cases also the excessive cost of real estate has made it necessary to secure long time leases and install substation apparatus in the basements of large fire-proof buildings.

As the development of sub-stations has introduced an additional link in the chain between the generating unit and customers' service, it is of the greatest importance to make this link effective and reliable.

Abstracts from Foreign Contemporaries

Experiments on Nernst Lamps.—Herr von Gaisberg has communicated to the *Elektrotechnische Zeitschrift* the results of some life and efficiency tests on 110-volt Nernst lamps obtained by the Hamburg Inspectorate of electric lighting. The lamps were taken from stock, being of the type known as the "B pattern," with a straight filament stretched horizontally below the flat zigzag heater. No trouble was experienced with the series resistances, which were designed for 15 volts. During the tests, the lamps were extinguished twice every 24 hours, but switched on again after having cooled down. They were equipped with globes of opal glass and the photometric measurements were made in the axis of the lamps. It is likely that the values obtained in the direction of the axis are not very different from those relating to any point within a cone with an angle of 90° at the apex. The results are given below.

No. of lamps.	Hours of burning.	Mean pres. at lamps in volts.	Consumption in watts.	C.p. in direc. of the axis. (Hef. units).	Consump. per Hefner c.p.

The Hefner is smaller than our unit of candle-power, the ratio being about 1 to .88.

Improvements in Oil Engines.—The accompanying illustrations (Figs. 1 and 2), taken from the *Mechanical Engineer* of London, give respectively longitudinal and cross-section of an internal-combustion engine, embodying some improvements by A. G. Melhuish. These consist in connecting the suction cylinder by a pipe to a small closed cup, and in fitting this cup with an outlet valve and pipe connected with the vaporizer when oil is used. Also in fitting a valve-controlled inlet pipe from an oil container, the pipe being fitted on a non-return valve. Referring to the suction cylinder *A* is connected by a pipe *B* to a small closed chamber *C* having a cup C_1 formed at the bottom, having an outlet valve *D* and pipe *E* which is connected to the vaporizer *F*. A valve-controlled inlet pipe *G* runs from an oil container *H* to the cup C_1, the inlet pipe *G* having a non-return valve *I* to prevent return of oil. This construction renders the engine effective for using heavy oils, and on the instroke of the suction and working pistons *J* J_1, due to explosion of the charge in the working cylinder A_1, a partial vacuum is formed in the cylinder *A* and pipe *B*, this vacuum acting through the chamber *C*, valve *K*, and pipe *G* on the oil in the tank *H*, and sucks a portion up through the valve *I*, pipe *G*, and valve *K*, and leaves it in the cup C_1. During this action the piston J_1 first uncovers the exhaust port *L*, and in consequence the greater part of the exploded charge escapes, and on a farther travel of the piston J_1 the port *M* will be uncovered, and in so doing the remaining products are sucked into the chamber *N* and suction cylinder *A*, due to the vacuum in same, and at the same time draw in a new combustible charge through the valve *P*. On the return of the piston *J* and J_1, the piston J_1 will first close up the port *M* and

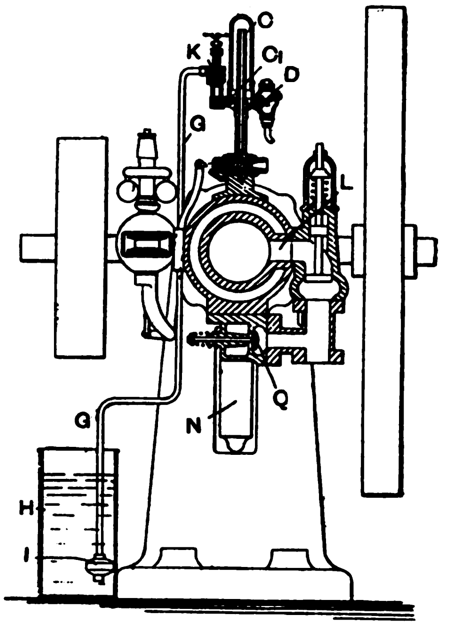

FIG. 2.—CROSS-SECTIONAL VIEW OF OIL ENGINE.

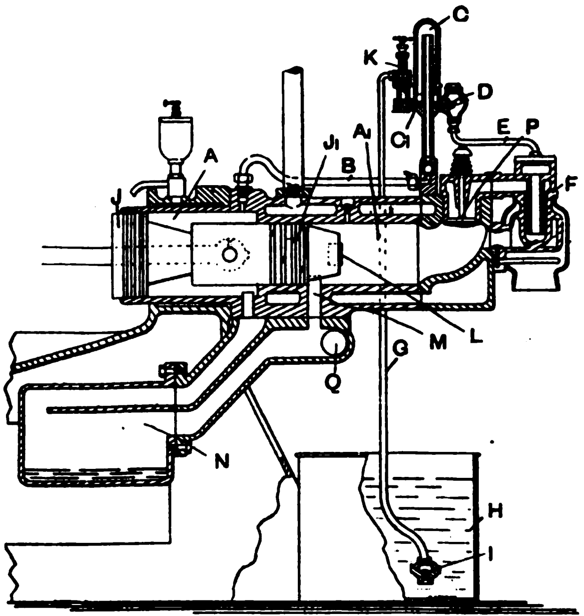

FIG. 1.—LONGITUDINAL SECTION OF OIL ENGINE.

prevent any of the previous charge sucked in the chamber *N* re-entering the explosion cylinder, the piston *J* will drive a portion of the charge which was sucked in the chamber *N* out through the valve *Q*, and also drive the oil previously sucked into the cup C_1 through the valve *P*, pipe *E* to the vaporizer *F*, the piston J_1 at the same time compressing the charge to the firing point for a repetition of the previous cycle.

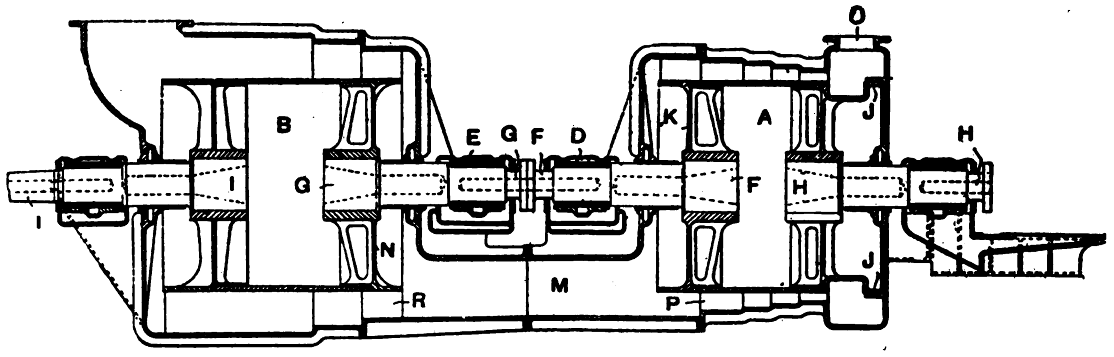

FIG. 3.—IMPROVEMENTS IN STEAM TURBINES.

Improvements in Steam Turbines.—A recent patent granted to Charles Parsons and A. D. Wass, and abstracted in the London *Mechanical Engineer*, relates to the construction more especially of very large turbines, but is also applicable to smaller sizes, the object being to diminish the size of the parts of the turbines by enabling them to be divided into distinct elements generally for placing in series on the steam. The invention consists in dividing up a turbine into two or more parts in tandem on a shaft by interposing external bearings and employing balancing diaphragms not requiring running packings. Referring to Fig. 3 the elements *A* and *B* of a turbine are placed in series on one shaft. Between the two elements the bearings *D* and *E* are placed in which the shafts *F* and *G* rotate. It will be seen that the shaft does not pass the whole way through the drums of the turbine, but is made in parts *F G H I* for convenience of construction. The high-pressure element *A* is provided at the steam inlet end *O* with a dummy piston *J*. At the outlet end *P* of the high-pressure element the turbine drum is closed by a diaphragm *K*, while a passage *M* leads to the inlet side *R* of the low-pressure turbine, the drum of which is closed near the inlet end by means of a diaphragm *N*. The diaphragms *K* and *N* are of the same diameter, and since they are subjected to the same pressure in opposite directions the end balance of the two turbines as a whole is the same as if they had not been divided, and the size of the dummy piston *J* and other parts are regulated by the same conditions as in other forms of Parsons turbines. This arrangement may be applied to turbines arranged in multiple elements on parallel shafts. In such cases each shaft has at least one dummy piston placed at the inlet end of the highest pressure element. The other elements on the same line of shafting have not dummy pistons unless the number of such elements is too great to allow of adequate balancing being obtained by one dummy piston on the highest pressure element.

Automatic Boiler-Feed Regulator.—The accompanying illustrations show a new design of regulator for automatically adjusting the feed supply to steam boilers so as to preserve a constant level in the boiler, which is described in a recent issue of the *Mechanical Engineer* of London. The method of operation will be readily followed from the illustrations. The apparatus is attached to the boiler at *N*, from which water or steam can enter into the tube *F*, according as the opening is below or above the water level. The feed on its way to the boiler passes through the outlet *C* and chamber *D*, and then out at *E* as shown, the object of this circulation being to cool the water from the boiler entering the expansion tube, *F*. So long as the tube, *F*, is open to the steam space in the boiler it remains full of steam, and the feed water in passing through *D* simply gets heated up by its contact with the tube, but the moment the steam supply from the boiler is shut off by the rising of the water level and closing of the passage, *B*, the cold (or partially cold) water surrounding the expansion tube condenses the steam in it and causes the water from the boiler to take its place, and so by partially or wholly filling the tube with water that has been partially cooled down by the feed-water passing through the chamber, *D*, a marked difference is effected between the temperature of the tube when full of steam and extended, and when full of water and contracted. When the water level drops below the line *O* (say to *N*), the water in the tube *F* runs out by gravity, and being replaced with steam is thereby expanded and extended to its full length. This extension relieves the rods *G* and G^1 and the lever, *H*, and by so doing allows the pull of the spring *I* to act upon the lever *J* (the pressure of which on the rod *K* has been relieved by the easing off of the lever *H*), thereby pushing down and closing the by-pass valve *L*. On the other hand, when the water level rises and water rises in the tube *F* and contracts it, the pressure on the rods *G* and G^1 depressees the lever *H* and rod *K* by relieving the spindle of the valve *L* of the pressure of the spring *I* (by the depression of the lever *J*), and leaves the by-pass valve *L* free to open.

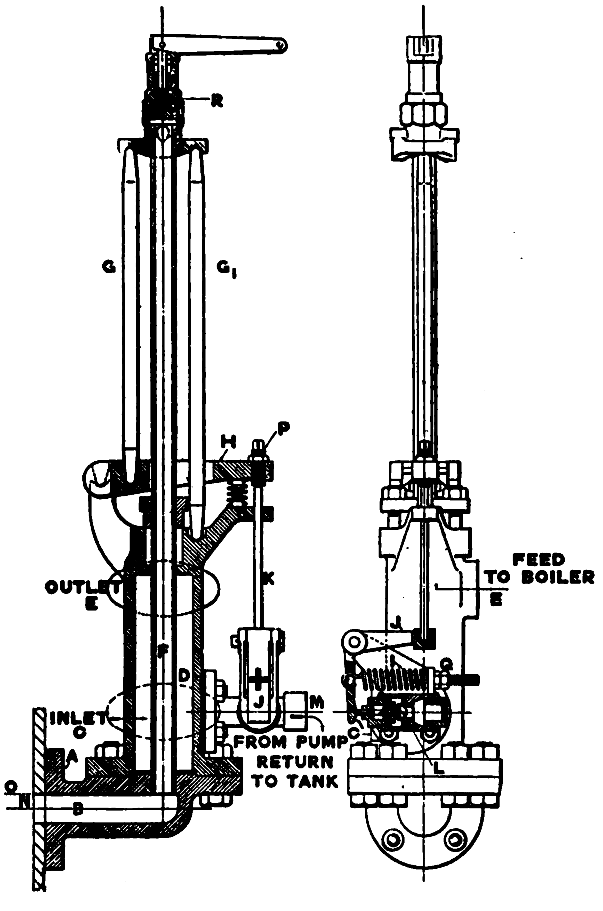

FIG. 4.—AUTOMATIC BOILER FEED REGULATOR.

A Water-Seal Steam Trap.-The accompanying illustration shows a new water-seal steam trap brought out in England and described in a recent issue of the London *Engineer*. The apparatus consists of a head, *A*, with an inlet and outlet the same diameter as the main steam pipe, so that it can be inserted at any point in that line. There are also two baffle plates, *B* (see Fig. 6), which form part of the casting, having two drain holes at the bottom. At one side of the head is a casting forming the discharge valve. The construction of this can be readily seen from Fig. 5. Screwed into the head, in a vertical position, is the sensitive tube, which is made of gun-metal. The diameter of this tube is never less than that of the main steam pipe. Attached to the lower end of the sensitive tube is the spherical water-seal trap. Two steel rods *C* are screwed into lugs cast on to this portion, and are of such a length that they just touch the lever *D* at a distance from the fulcrum equal to one-ninth the length of the lever. By this arrangement any upward movement of the rods *C* will lift the discharge valve *F*. A pipe runs from the discharge valve connection at the top of the head, through the sensitive tube, nearly to the bottom of the trap. Wet steam and water pass along the main pipe, and enter the apparatus at *A;* water then passes into the trap through the recess in the baffle plate. The water which is carried on in suspension passes through an area larger than that of the steam pipe, and further separation results. This water drops into the trap by gravity, and dry steam passes along. The apparatus is therefore a separator as well as a trap. The water-seal chamber gradually gets full of water, which then creeps up the sensitive tube. This water, coming in contact with the gun-metal, slightly cools it, and contraction takes place. The rods *C* are thereby raised, and the discharge valve opened. Water immediately flows up the discharge pipe and through the valve. By this means the water soon leaves the sensitive tube, and is replaced by steam. The temperature rises, the tube expands again, and the valve is consequently closed. This cycle is then repeated.

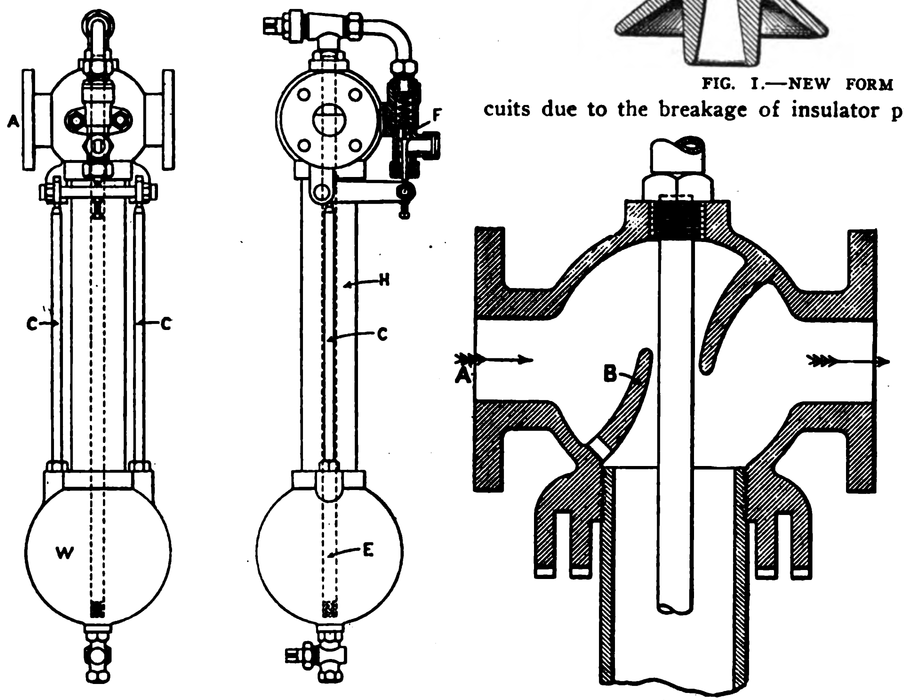

FIG. 5.—WATER SEAL STEAM TRAP AND HEAD OF TRAP.—FIG. 6.

Reduction of Clearance in Oil Engines—In oil engines of the kind in which the vaporizer is connected to the ends of the combustion chamber of the cylinder by means of a narrow neck, the vaporizer and air inlet and exhaust valves have been so arranged that a considerable space or clearance exists in the air inlet and exhaust valve box and between the neck of the vaporizer and the piston when the latter is at the end of its stroke. With a view to avoiding these clearances, the arrangement shown in Figs. 7 and 8 has been designed, and a description of it is given in the London *Mechanical Engineer*. Referring to the illustrations, *A* represents the cylinder of the engine, which is provided with the usual liner *B* and with the piston *C*. *D* is the vaporizer connected to the combustion chamber of the cylinder by the neck *E*, which is formed in the cylinder end *F*, and is curved so that the vaporizer may be located at the side of the cylinder. *G* is the air-inlet valve and *H* is the exhaust valve, these valves being mechanically actuated by levers *I*, one only of which is shown, and which are actuated from the engine by any of the usual methods. The air-inlet valve *G* and the exhaust valve *H* open inwardly relatively with the cylinder, the piston *C* only leaving a very slight clearance at the end of its instroke, as indicated. The valves *G* and *H* follow the piston at the commencement of its outstroke, and to avoid the liability of their coming into contact with the piston *C*, which might happen in the case of quick-running engines, the piston may be made with recesses opposite the valves. The arrangement of the valves and the vaporizer neck in the end of the cylinder enables the amount of clearance heretofore necessary to be very materially reduced, thus increasing the efficiency of the engine, since it is possible to obtain a better compression and the introduction of a larger quantity of compressed air into the vaporizer.

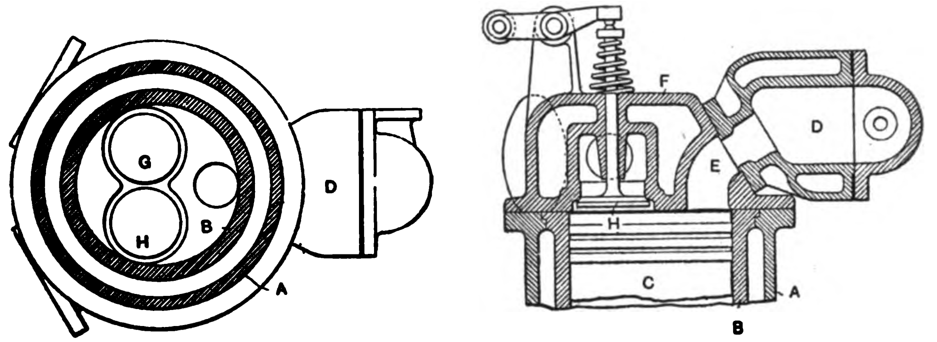

FIG. 7.—SECTIONAL VIEWS OF OIL ENGINE.—FIG. 8.

SOME RECENT ELECTRICAL PATENTS

Insulator.—In order to eliminate the liability of trouble on high potential circuits due to the breakage of insulator pins the form of insulator and pin illustrated by Figs. 1 and 2 herewith has been devised by Fred M. Locke, of Victor, N. Y. The engravings are practically self-explanatory; the insulator has two petticoats, one at each end, and a hole all the way through the centre, so that the pin may be slipped through it and supported at both ends, as shown in Fig. 2. The upper petticoat of the insulator is provided with an eaves

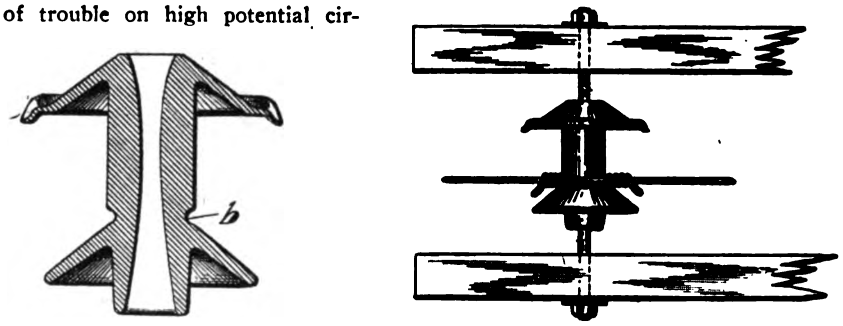

FIG. 1.—NEW FORM OF INSULATOR AND PIN.—FIG. 2.

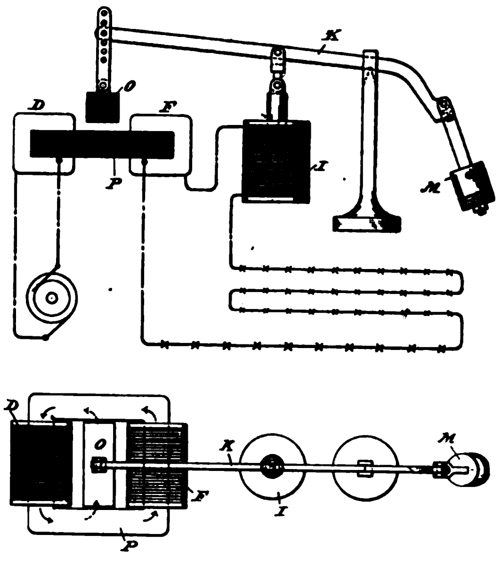

FIG. 3.—HALLBERG'S REGULATOR FOR SERIES CIRCUITS.

trough having drain spouts. The wire groove is located near the top of the lower petticoat, as indicated at b, in Fig. 1.—Patent No. 767,948.

Regulator for Series Alternating Current Circuits.—One might have been pardoned for supposing that every practical form of automatically-variable reactance coil for series alternating-current circuits had been devised some time ago. That this is not true, however, is made apparent by the issuance of a patent to J. H. Hallberg, of New York, for the arrangement shown in Fig. 3. This consists of a core, P, having a closed magnetic circuit, and two coils, D and F; a magnetic bridge or shunt, O, suspended from a lever, K, and counterbalanced by a weight, M, and a solenoid, I, arranged to pull the lever downward and thus introduce the bridge, O, into the stationary core, P. It is evident that the mutual inductance between the coils, D and F, may be varied widely by changing the position of the bridge, P; when the latter is entirely within the opening in the main core, the mutual induction is minimum and the e.m.f. of the coil, F, is, therefore, minimum. The operation is practically obvious from an inspection of the diagram. If lamps are cut out of the work circuit, a momentary increase in the current results, and this causes the solenoid, I, to draw the bridge, O, down into the main core until sufficient magnetic flux is shunted out of the coil, F, to reduce the current to normal. Then the pull of the soleneid, I, is just balanced by the weight, M. A feature peculiar to this form of regulator is that the power factor of the work circuit is kept practically constant by the increase in the self-induction of the solenoid, I, when its core moves downward and thereby reduces the self-induction of the coil, F, by shunting part of the flux out of its leg of the core. Patent No. 722,096.

Concerning Boiler Tube Cleaners.

To the Editor, American Electrician:

Our attention has been called to an article which has appeared in some of the technical journals in which remarks concerning the effect of using certain types of tube cleaner might possibly be construed as intimating that the cleaners made by us have a deteriorating effect on the tubes. In order to correct any erroneous impression in this direction we wish to state that none of the cleaners made by us delivers a blow to the tube in removing its scale; nor is steam used in driving the cleaners. The work is all done by means of rotating cutter wheels which merely grind the scale away without doing any injury whatever to the tubes.

THE LAGONDA MANUFACTURING CO.
Springfield, Ohio.

CENTRAL STATION ENGINEERS.

II.

Robert E. Richardson.

Robert E. Richardson was born at Concord, Mass., on July 29, 1861. He attended the public schools at Concord until he was 15 years of age, and then prepared for college; entering the Massachusetts Institute of Technology and graduating from that institution as a mechanical engineer with the class of '85. During the fall of 1885 and the following year he taught mathematics and started a manual training course in the military school near Chicago. He then entered the employ of the Western Electric Company in Chicago, remaining with the company four years, during which time he served in various departments and erected and operated many stations. During the latter part of 1889 and in 1890 he was manager of the Milwaukee Electric Light Company. In 1891 he became affiliated with an engineering construction company in Chicago, and in 1892 assisted R. H. Pierce at the Columbian Exposition in Chicago, laying out the arc light system, etc. At the close of the Exposition he became assistant manager of the Ansonia Electric Company, having charge of the lighting and power department. On March 1, 1894, he went into partnership with R. H. Pierce under the firm name of Pierce & Richardson, which company was afterward incorporated under the name of Pierce, Richardson & Neiler, consulting engineers. It was while connected with this company that Mr. Richardson was made manager of the consolidated properties of the Kansas City Electric Light Company. Under his careful guidance these properties were thoroughly rebuilt, and so pleased were the directors with his work that he was asked to remain and devote his entire time to the management of the Kansas City Electric Light Company. The phenomenal growth of this property under his management was recorded in our description of the plant in the June number. The development both in volume of business and improved economy of operation is probably unequalled in the history of electric lighting. Mr. Richardson stands high in engineering, social and sporting circles. He is a member of the American Institute of Electrical Engineers, Kansas City Club, Commercial Club, Driving Club, and one or more golf clubs, and takes an active part in public affairs. He is an athlete and a musician, and has other accomplishments which have endeared him to a host of friends both in Kansas City and among engineers and business men in Chicago and throughout the rest of the country.

ROBERT E. RICHARDSON.

NOTES.

Interstate Independent Telephone Association will hold its annual convention December 13 to 15 inclusive, in Chicago, with headquarters at the Auditorium. A large attendance is expected by the officials of the association. Special rates have been granted by all the railroads concerned; they may be ascertained from the local agent in any town or city.

American Society of Mechanical Engineers. — The fiftieth meeting of this society will be held in the society's rooms at No. 12 West Thirty-first Street, New York, December 6 to 9 inclusive. There will be a number of unusually interesting papers, among which may be mentioned "Computation of Values of Water Powers," by Charles T. Main; "Condensers for Steam Turbines," by George I. Rockwood; "More Exact Method of Determining the Efficiency of Steam Boilers," by A. Bement, and "The Forcing Capacity of Fire-Tube Boilers," by Francis W. Dean.

Alternating-Current Traction from Gas Power.—The Warren & Jamestown Street Railway Company is engaged in equipping a railway system extending between Warren, Pa., and Jamestown, N. Y., which will involve two departures from the conventional path of railway practice, namely, the use of gas engines to drive the generators in the power-house and of single-phase, alternating-current motors on the cars. The power-house will be located at Stoneham, Pa., two miles from Warren, and the initial equipment is to consist of two Westinghouse gas engines of 500 horse-power capacity each, direct connected to Westinghouse alternators. Natural gas will be used in the engines. Five transformer sub-stations will be distributed along the route and these will, of course, reduce the transmission voltage to a suitable e.m.f. for delivery to the car equipments. The latter will be Lamme single-phase type adapted for operation also on the direct-current lines within the cities at each end of the line.

Electrical Engineering at the Brooklyn Polytechnic Institute.— Dr. Samuel Sheldon, head of the Department of Electrical Engineering at the Polytechnic Institute of Brooklyn, has made a decided innovation in the course in electrical engineering given at that institution. Hereafter the well-beaten paths of academic instruction heretofore followed in this, as well as in other technical institutions, will be somewhat departed from, and while the fundamental training of the student will be entrusted to the corps of regular instructors, the strictly electrotechnical instruction will be given by a staff of engineers, technical authorities in their several specialties, who will act as consulting professors. The instruction given by the latter will be delivered at evening sessions and will form a complete course from a purely technical viewpoint. Engineers and others desiring to complete their technical education will be enrolled, and at the expiration of the course will be eligible for a degree. The consulting professors thus far appointed are as follows: Dr. Louis Duncan, electric traction; Dr. F. A. C. Perrine, electric power transmission; Mr. W. S. Barstow, central station engineering; Mr. Charles F. Scott, commercial engineering; Thomas D. Lockwood, telephony, telegraphy and patent practice.

Calorific Power ot Liquid Fuels.—In a paper recently published in the *Revue Technique*, M. L. Levi makes the following comparison between the calorific values of different fuels used in internal-combustion engines: British thermal units per pound—Methylated alcohol, 10.620; methylated alcohol mixed with 50 per cent gasoline, 14,200; crude American oil, 19,630; refined American oil, 19,880. The mixture of methylated alcohol can, it is stated, be used as easily as ordinary gasoline, but with unmixed gasoline it is necessary to warm up the carbureter a little before starting, as the alcohol does not vaporize readily enough below a temperature of 68° F. As an alternative gasoline may be used at the start, the alcohol being supplied later. No trouble is found with the admission valves in using alcohol, and if at times there is a deposit of soot or tar, this arises generally from the use of a bad carbureter. A little acetic acid results on combustion, but not enough to cause damage. The carbureter should be of a type which will deal out a measured quantity of the liquid at each suction stroke. The exhaust gases are free from the unpleasant smell prevalent in the case of gasoline motors. The principal objection to the use of spirit lies in cost, which, to compete with gasoline, should be about 20 cents per gallon in place of about twice as much, as at present the case in France. In Germany the cost of methylated alcohol is only about 18 cents per gallon, so that the alcohol motor is becoming more and more popular there.

New York Central Electric Locomotive.— The high-speed electric locomotive built by the General Electric Company and the American Locomotive Company for the New York Central & Hudson River Railroad Company was given its first public test on Saturday, November 12. The demonstration took place on a special section of track equipped with a third rail between Schenectady and Hoffman's, N. Y., and was satisfactory in every respect. The general dimensions and data applying to the locomotive are as follows:

No. of driving wheels	8
No. of pony trucks	2
Total weight of locomotive, tons	95
Weight on drivers, tons	69
Rigid wheel base, ft.	13
Total wheel base, ft.	27
Length over buffer platforms, ft.	37
Extreme width, ft.	10
Height to top of cab, ft.	14.3
Diameter of drivers, ins.	44
Diameter of pony truck wheels, ins.	36
Diameter of driving axles, ins.	8.5
Normal rated horse-power of locomotive	2,200
Maximum horse-power	3,000
Normal drawbar pull, lbs.	20,400
Maximum starting drawbar pull, lbs.	32,000
Speed with 500-ton train, m.p.h.	60
Voltage of current supply	600
Normal full load current, amp.	3,050
Maximum full load current, amp.	4,300
No. of motors	4
Type of motor	GE-84-A
Rating of each motor, h.p.	550

The locomotive has four driving axles, on each of which is mounted without intermediate gearing the armature of a motor having a normal rating of 550 horse-power. The total rated capacity of the locomotive is 2200 horse-power, although for short periods a considerably greater power may be developed, thus making the electric locomotive more powerful than the largest steam locomotive in existence. The motor has two poles with flat faces so as to allow a large relative vertical movement between armature and poles as the latter move up and down with the riding of the frame upon the springs. The main frame of the locomotive is of cast steel and serves not only as the mechanical frame of the locomotive, but also as part of the magnetic circuit of the motors. The four motors are arranged in tandem, the end pole-piece being cast as part of the end frames and the double pole-pieces between the armatures being carried by heavy steel transoms bolted to the side frame and forming part of the magnetic circuit as well as cross braces for the truck. The field coils are wound upon metal spools which are bolted upon the pole-pieces. The brush-holders are mounted upon insulated supports attached to the spring saddle over the axle journal, thus maintaining a fixed relation to the commutator. These brush-holders are made adjustable so as to allow for wear of the commutator and journal bearings. The dead weight on the axle is not materially greater than is customary with steam locomotives, and in addition there is no unbalanced weight to produce vibration with attendant injuries to track and roadbed construction. The actual reduction in the expense of maintaining the rails and roadbed, due to the absence of pounding and rolling, will have a great bearing on the upkeep of the permanent way. The superstructure consists of a central cab for the operator, containing master controllers, engineer's valves and switches and valves required for operating the sanding, whistling and bell-ringing devices. This apparatus is furnished in duplicate, one set on each side of the cab, and is arranged so as to be easily manipulated from the operator's seat, while at the same time a practically unobstructed view to front and rear may be obtained from the windows. There is a central corridor extending through the cab, so as to permit access from the locomotive to the cars behind, and the contactors, rheostats and reversers are arranged along the sides of these corridors in boxes of sheet steel which are sheathed on the inside with fire-proof insulating material. The control system permits three running connections, namely, four motors in series, two groups of two in parallel series, and all four motors in parallel. The motor reverser, contactors, rheostats and other controlling appliances are all of the Sprague-General Electric multiple-unit type. The master controller is fitted with a special operating lever and is capable of being moved through an angle of about 75 degrees. A current-limiting device is provided in the master controller, consisting of a friction clutch operated by an electromagnet which is energized by the current passing through one of the motors, the arrangement being such that when the current exceeds a predetermined amount the cylinder cannot be rotated further until the current has fallen sufficiently to permit the relay to drop. Current is collected from the third rail by multiple-contact, spring-actuated, third-rail shoes whose supports are carried on channel irons attached to the journal boxes. There are four of these shoes on each side of the locomotive. The large number of switches and crossings in the yards at the terminals necessitates an overhead construction in places and additional contacts are therefore mounted on top of the locomotive for collecting current when the locomotive is passing through these points. These devices may be raised and lowered by air pressure controlled from the engineer's cab. A magnetic ribbon fuse is placed in circuit with each shoe and overhead-contact device so as to secure protection in case of accidental short-circuit. Current for operating the locomotive is obtained from a rotary converter sub-station at Wyatt's, which is supplied with 11,000-volt, 25-cycle, three-phase current from Schenectady. The voltage of the current supplied to the locomotive is 600. The maximum speeds reached in the trial were 63 miles per hour with an eight-car train and 72 miles per hour with a four-car train. The trial section of track, however, was only four miles long, so that higher speeds could not be attained. Throughout both the starting and running tests, the locomotive showed remarkable smoothness and steadiness in operation. The maximum input recorded at the trial was 4200 amperes at 460 volts, giving an output of 2200 horse-power available at the wheels. With 4200 amperes at a potential of 600 volts the output available at the wheels would be 2870 horse-power. This is secured without in any way exceeding the safe commutation limit of the motors and with a coefficient of traction of only 22.5 per cent of the weight upon the drivers.

ESTABLISHED 1889.

American Electrician

A Journal of Practical Electrical and Steam Engineering.
WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Published on the first of each month by the
McGraw Publishing Company,
114-118 Liberty Street, New York.
Telephone Call, - - - 7606 Cortlandt.

Branch Offices:
Philadelphia: 929 Chestnut Street.
Chicago: Monadnock Block.
Cleveland: Cuyahoga Building.
London: Hastings House, Norfolk St., Strand.
St. Louis Headquarters:
Section 1, Electricity Building,
Louisiana Purchase Exposition.

Address all business communications to
AMERICAN ELECTRICIAN.

Copyrighted, 1904, by McGraw Publishing Co.

Entered at the New York Post Office as second class mail matter.

Subscription, - $1.00 Per Year
In the United States, Canada and Mexico.
FOREIGN COUNTRIES, $2.00.

NOTICE TO SUBSCRIBERS.

Subscribers will find on addressed wrappers of their papers the date on which their subscriptions expire. This is the only method of acknowledging the receipt of subscription payments.

In requesting change of address both the **old** and the **new** address should be given.

NOTICE TO ADVERTISERS.

Changes in advertisements should reach the office of the American Electrician by the 15th of each month in order to appear in the following issue. New advertisements can be received up to the 25th of each month.

Vol. XVI. DECEMBER, 1904. No. 12

The American Electrician has a larger paid subscription list than any other electrical journal in the world.

Central Station Records.

The importance of keeping operating records in central stations of even the smallest output is fairly well recognized, and now that plant operation has been reduced to the most rigid business basis no station succeeds in which some sort of operating record is not kept. One of the most vexatious features of record keeping is the determination of the extent to which such records shall be detailed. If the records are too complete, they entail a disproportionate amount of labor in the making and also in the analysis of them, and eventually the work degenerates into perfunctory tabulation and filing, without any analysis beyond comparing the monthly or annual cost of variables with the income for the corresponding period.

It is scarcely necessary to say that every station should be equipped with curve-tracing instruments, as well as indicating instruments, so that the "running" performance of each unit may be inspected day by day; in fact, if it should come to a question of choosing between indicating instruments alone and charting instruments alone, we should strongly prefer to use the latter, excepting the voltmeter, of which both types should invariably be employed: it would be the silliest kind of "economy" to omit either. Charting steam gauges should also be used, one on each boiler or permanently connected battery of boilers and, advisedly, though not indispensably, one at the steam chest of each engine. With these labor-saving appliances and a simple system of weighing coal and measuring water, the hourly performance of a station may be readily reduced to graphic form, curves of the work in each division of the equipment being drawn on a single chart to facilitate direct comparison and analysis. When a continuously recording steam engine indicator shall have been developed, this will still further simplify the work of analyzing the hourly operation of a plant.

Factory Motors.

It is a well-known fact that the motors in most industrial establishments rarely are operated at full load continuously for considerable periods of time. Leaving out textile mills, daily newspaper press rooms and a few other establishments which may be classified as special, the average electric motor will probably not run at full load during more than 60 per cent of the total working time of each year; this is especially true of machine-tool motors, some of which run at half or a third load for hours at a time. This leads to some deductions which may be useful in the selection of motors for driving industrial machinery—particularly in cases of individual drive or small groups driven by one motor. Obviously, a motor may be used of lower rating than if it had to carry full load continuously 10 hours per day, but it must have a considerably higher percentage of temporary overload capacity than a machine running on a steady load.

As examples of the relation between motor capacity and output in watt-hours per annum the following will be appropriate. In a plant devoted to the building of rather heavy machinery and operated by electric motors, the aggregate capacity of the motors was 590 horsepower. During one month of 26 working days, the total energy delivered to the motors was between 57,000 and 58,000 kilowatt-hours. If the average efficiency of all the motors be taken at 90 per cent, which is rather liberal since the machines were induction motors, the total output figures out between 69,000 and 70,000 horsepower-hours, as compared with the total capacity of 145,730 horsepower-hours (26 days at 9½ hours per day). In another establishment devoted to commercial printing of all classes except the publication of periodicals, the total motor equipment aggregates 38 horsepower and the shop is operated 56 hours per week. The meter bills for three months, during a reasonably busy season, aggregated an amount based on the equivalent of 14,400 horsepower-hours. The motors in this case are direct-current machines and will doubtless average 85 per cent efficiency, the average size being much smaller than in the machine-shop cited. This gives the plant a total capacity, for three months, of 32,540 electrical horse-power-hours. In both of the plants all of the motors were operated during almost all of the time considered, so that the discrepancy between the capacity and the actual output was due almost exclusively to the fact that the motors were operated at less than full load most of the time.

In many establishments, of course, especially where individual motor drive is employed, each motor lies idle a part of each week if not a part of every day, so that even if the motors run continuously at full load while they are active, the monthly load in watt-hours is less than the motor rating of the plant. Consequently, in estimating beforehand the probable cost of operation, the figures, if possible, should always be based on records taken from existing plants of the same general class. In plants where both of the conditions mentioned are likely to exist, the actual cost of operation will, of course, show a greater discrepancy in comparison with the total rating of the motors than in those establishments involving either partial idleness or underload operation alone.

Connections of Railway Generators.

By usage it has become the rule to connect up railway generators so that the positive terminals are connected to the trolley wire or third rail, as the case may be, and the negative terminals to the track rails. In order to simplify the switchboard construction, the control is single-pole, the negative lead being carried to the track feeder without going to the main switchboard at all. In some cases, the series winding and equalizer connection are at the negative side of the armature; in others, at the positive, or line side. Equalizing on the negative side has the disadvantage that an accidental "grounding" of the armature winding or of the commutator on the core will produce a short-circuit which will not operate the circuit-breaker, the latter being connected, of course, in the positive lead of the machine. On the other hand, equalizing on the positive side of the generator involves carrying the negative lead to the switchboard, because the ammeter and circuit-breaker must be inserted in that lead. It seems plain that the preferable solution, at least in average cases, is to equalize on the negative side and provide a switch pillar near each machine, the pillar to carry the equalizer switch and a single-pole circuit-breaker inserted in the main negative lead. This would eliminate the circuit-breaker from the list of switchboard apparatus and further simplify the construction there; it would, moreover, obviate the liability of having a circuit-breaker "blow" uncomfortably near one's face upon closing a positive switch on a short-circuited or overloaded circuit.

Speaking of closing a switch on a short-circuit recalls an ingenious and simple expedient employed in a certain small power house a number of years ago for the purpose of preventing just such a disagreeable probability. A bank of five 115-volt lamps was connected in series between the line terminal of the circuit-breaker and the generator terminal of the corresponding main switch; all of the lamps were out of sight except one, which was colored deep red and mounted on the board between the main switch and the circuit-breaker so that it was obtrusively visible to anyone trying to close either the switch or the circuit-breaker. With a short-circuit on the feeder, the lamp glowed at practically full candle-power when either the switch or the circuit-breaker was open; with one or more motormen "feeling" for current with their controllers, the lamp glowed dimly; with a perfectly clear line, it remained dark, of course. One of these lamp banks was connected permanently across each switch and circuit-breaker so as to avoid the trouble of switching a single bank from one feeder to another. It is a good investment for any small power station.

The Consulting Engineer.

Paraphrasing an old adage, "He who is his own consulting engineer has a fool for a client," presuming that "he" is not an engineer of unusually wide experience. The manager or engineer of any except a very large central station who attempts the remodelling or important extension of his plant without consulting some outside engineer who has had wide experience in just that class of work is quite sure to regret it sooner or later. A man concerned with the practical management of one plant cannot possibly keep thoroughly abreast of all developments in the art nor can he keep informed as to the detail experience of other plant managers, although the National Electric Light Association has done a vast deal toward reducing this latter handicap. Consequently, when his plant requires any wholesale "doctoring," it is most wise to go out into the world and get the assistance of someone who is entirely impartial, capable of analyzing conditions with the least expenditure of time and effort, and experienced in the application of remedies to central station ills. Here is where the consulting engineer comes in in central station practice; also the consulting accountant, although the number of cases where the services of an expert accountant are required by a central station is relatively insignificant.

There is no greater fallacy than that of assuming that because a central station plant is relatively small, the owners cannot afford to engage a consulting engineer to supervise any extensions or modifications of importance that the development of business may render advisable. Numerous instances of deplorable wastes of money on plant additions and extensions undertaken without advice from the outside have come without our own observation during the past ten years. The opinion is apparently held by the financial sponsors of electric light and power plants that the man in charge of the technical end of the establishment should be capable of doing all the engineering necessary and of keeping the plant strictly up to date in all of its equipment and operating methods. And the operating engineers themselves appear to feel that it would be reflection on them to call in an outside expert when important changes are necessary. Possibly the respective attitudes of the two classes of men are mutually fostered. However that may be, both are wrong when it comes to extensions of any magnitude in plants not large enough to justify the regular employment of a staff of engineers in contradistinction to a single engineer who is burdened with every technical responsibility connected with the plant and sometimes with its active business management also.

Engineering English.

While one may very well make one's meaning clear to others by the use of ungrammatical language or uncouth diction, it does not follow that good grammar and clean diction will not convey the meaning much more clearly, leaving out the question of euphony and any consideration of the sensibilities of the reader or hearer. There being no utilitarian excuse for the use of poor diction or the violation of elementary rules of grammar, it is difficult to conceive why educated, or supposedly educated, engineers persist in ascribing personality to pieces of machinery, using both the singular and plural numbers in referring to the same collective noun, describing a deduction first, then the method and finally the premises, or indulging in any other vagaries of expressions or composition. We do not by any means advocate pedantic diction, and we quite agree that some colloquial expressions are better adapted to some purposes than more dignified verbiage would be, but we do wish that engineers—especially young engineers—would take the trouble to analyze their statements and weed out such expressions as "a 10-h.p. motor whose pulley" and "the Blank & Blank Co., which installed in their own factory," and when not too hard pressed for time, revise their writings so as to put statements in logical sequence and eliminate unnecessary verbiage. It would undoubtedly go a considerable distance toward improving their professional reputations. Incidentally, we might say that these remarks are *not* inspired by any manuscript received for publication in this journal, although the casual reader might easily infer that to be the case.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

After having settled the diameter of the polar bore and, consequently, that of the armature core, the number of armature coils must be checked up with regard to the type of winding desired. A simple lap winding, having as many paths through it as there are poles on the field magnet, requires no study; the only consideration is that the number of coils shall be a multiple of the number of field magnet poles. A wave winding is more difficult to deal with. The number of coils for a four-pole machine must be odd; the number for a six-pole machine must be a number *not* divisible by three; it makes no difference whether the number is odd or even. These principles are covered by Rules VI and VII.

Rules.

Rule VI.—The number of coils in a lap-wound armature must be even, and should be a multiple of the number of field magnet poles.

Rule VII.—In a four-pole machine the number of coils in a wave-connected armature may be any odd number.

In a six-pole machine the number of coils in a wave-connected armature may be any number not evenly divisible by 3.

Rule VIII.—The number of wires in a slot must be divisible without a remainder by twice the number of turns per coil.

Rule IX.—In a four-pole machine, with a two-path armature winding, if the number of armature coils = 2 × the number of slots, one coil must be "dead-ended" and left unconnected to the commutator. The remaining coils constitute the "active" coils of the armature.

In a six-pole machine with a two-path armature winding, if the number of armature coils = 3 × the number of slots, one coil must be "dead-ended" and left unconnected. The remainder constitute the "active" coils.

Rule X.—Each armature coil in any machine should span one tooth less than (total teeth ÷ poles), discarding any fraction.

Rule XI.—The terminals of each armature coil must be connected to two commutator segments between which there is the number of segments specified in Table VII.

Rule XII.—The diameter of a commutator barrel must be not less than 0.06 times the number of segments and not more than 6000 ÷ r.p.m.

Rule XIII.—The number of groups of brushes must be two for a wave-connected (two-path) armature winding: For a lap winding, the number of groups of brushes must equal the number of field magnet poles.

Rule XIV.—The total area of all the brush faces must be not less than the armature current per wire ÷ 16 and not more than the armature current per wire ÷ 12.

TABLE VI.—Maximum Safe Number of Turns per Armature Coil.

Amperes per armature wire.			Maximum turns per coil.

0.31	....	....	27

When the actual current per armature wire falls between two of the numbers in the proper column of the table, take the number of turns corresponding to the greater of the two numbers between which the actual current lies.

If the number of slots and wires per slot do not give the proper number of coils, either the wires per slot or the number of slots must be revised to suit. For example, if we are laying out the armature of a four-pole machine which is to have a wave winding, the number of active coils must be odd, and if the total number of coils is equal to the total number of coil slots, then the number of slots must be odd. If, however, the number of coils is twice the number of slots, it makes no difference whether the number of slots is odd or even; but if there are three times as many coils as there are slots, then the number of slots should be odd. In a six-pole machine with a two-path (wave-connected) armature winding, if the number of slots is equal to the number of coils, it must, of course, be a number not evenly divisible by 3; if there are twice as many coils as slots, the number of slots must not be evenly divisible by 1.5, and if there are three times as many coils as slots, the number of slots may be any number whatever, but one of the coils must be left disconnected from the commutator, with the ends cut off close to the coil and taped heavily, as in the case of the four-pole, two-path armature with twice as many coils as slots. (See Rule IX.)

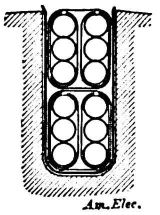

FIG. 4.

The relation between the number of coils and number of slots is determined by the number of turns per coil and the number of wires per slot. The number of wires per slot is necessarily equal to the number of turns per coil × number of half coils per slot. Referring to Fig. 4. there are six wires in the top half and six in the lower half of the slot; the upper six are separated

TABLE VII.—CONNECTION OF ARMATURE COILS TO COMMUTATOR.

For Two-Path Armature Windings.

The numbers in the body of the table are the numbers of commutator bars between the two to which the terminals of any one coil are connected.

NOTE.—The terminals of each coil of a lap-wound armature must be connected to adjacent commutator bars.

into two groups of 3 each, these 3 being the turns in one coil. There are four half coils in this slot, so that the total number of coils on the armature will be 2 × the number of slots. From this it will be evident that

The total number of coils = number of slots × wires per slot ÷ 2 × turns per coil.

Example: In the preceding article we found that slots containing 24 No. 13 wires could be used in a 5-h.p. armature, the allowable number of slots being 33. The current per wire being 10 amperes, the number of turns per coil, according to Table VI, could not exceed 4, consequently the number of coils would be $33 \times 24 \div 2 \times 4 = 99$, which is an odd number and therefore practical. But suppose we had tried to work with 20 wires per slot, instead of 24; the calculated number of coils would have been 82.5, which is obviously impossible, even regardless of odd or even numbers. It should be plain, from this, that the number of wires in a slot must be such that it is divisible without a remainder by twice the turns per coil. Hence Rule VIII.

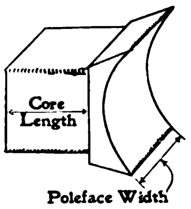

FIG. 5.

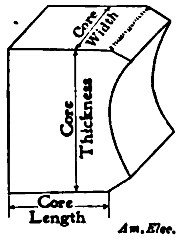

FIG. 6.

Having adjusted the number of slots satisfactorily, and finally settled the armature diameter, the commutator and brushes are the next features to consider. The number of segments in the commutator must equal the number of *active* coils, consequently the number of segments will be determined by Rule VII or VIII. The coils must be connected to the commutator segments in accordance with Rule XI; the construction of the coils and their arrangement on the core will be discussed fully in a future article.

TABLE VIII, continued.—Pole-piece Dimensions and Armature Length.

16	8 3/8	5 3/4	8 7/8	6 1/4

Note.—Armature cores ¼ inch longer than the pole-face width are to have ¼ inch spacer in the center of the core, to make a ventilating duct ¼ inch wide.

Cores 5/16 inch longer than the pole-face are to have a 5/16-inch spacer in the center; cores 3/8 inch longer, to nave a 3/8-inch spacer, and so on.

The diameter of the commutator barrel—that is, the part on which the brushes press—should be as small as it can be made without entailing mechanical weakness in the segment by making it too thin; on the other hand, the segments should be as thick as they can be made practically so that a brush will not cover too many segments. This leads to large diameters. Rule XII covers this case; the minimum allowable diameter, from the standpoint of mechanical strength of segments, is 0.06 times the number of segments, while the maximum allowable diameter, from considerations of friction between brushes and commutator and the tendency to spark on account of the segments passing a brush at too high a speed, is equal to 6000 divided by the revolutions per minute.

The brushes must be of carbon and mounted in holders which will be described later on. In order to avoid liability to overheating at the contact between the brush face and the commutator, the aggre gate area of all the brush faces must be sufficient to prevent the current per square inch of contact area from exceeding 32 amperes this result will be obtained by observing the first half of Rule XIV; the second part of this rule, limiting the total brush face area to one-twelfth of the current per armature conductor, is for the purpose of avoiding the use of unnecessary material.

The width of the field magnet pole face parallel to the shaft is given in Table VIII, and no departure should be made from these values. The gross dimension of the armature core parallel to the shaft is susceptible of slight variation by varying the ventilating duct, but the net dimension (gross length minus ventilating duct) *must* be equal to the pole-face width parallel to the shaft.

The cross-section of the field magnet core (that part enclosed by the coil) and that of the yoke part of the frame are given in Table IX and these figures must be followed as closely as possible. When round cores are employed, the cross-section cannot always be made to agree exactly with the figures in the table; then the nearest larger size of core must be used—never a smaller one. These figures are based on the use of either cast steel or very soft machinery steel for the magnet cores, and the softest obtainable cast iron for the yoke. If the yoke be made of steel its cross-section need be only ⅗ of the section given in the table for the particular diameter of polar bore. If the magnet cores be made of cast iron, as they might well be in the smallest sizes of machine, the cross-section of each core must be 2⅔ times the value given in the table.

In all four-pole machines, and in two-pole machines of 5 inches polar bore, or larger, it will usually be found advisable to make the poles with extended tips, as indicated roughly in Fig. 5. This will be determined largely, however, by the material used in the cores. If the builder, for any reason, is restricted to the use of cast iron in the magnet cores, then polar extensions will be impossible; in fact, in most cases it will be found that in order to obtain the required cross-sectional area in the core, the dimension transverse to the shaft will be greater than the chord of the pole-face arc. as indicated in Fig. 6; the core dimension parallel to the shaft must never be greater than the pole-face width. Figs. 5 and 6 illustrate the meanings of the terms "width," "thickness" and length," as applied to field magnet cores; also the meaning of "width" as applied to pole faces.

The Next Meeting of the National Electric Light Association will be known as the Denver-Colorado Springs Convention; business meetings being held in Denver and social meetings in Colorado Springs.

THE TESTING EQUIPMENT OF A COMMON BATTERY CENTRAL OFFICE.

BY A. DALLAM O'BRIEN.

The position of wire chief in a modern common-battery central office is one that requires not only a considerable amount of technical knowledge, but also no small amount of executive ability. To this position is entrusted the interior and exterior maintenance of the subscribers' lines and stations, as well as the switchboard and central office equipment.

With common-battery systems the question of line insulation is of the utmost importance. An insulation resistance which would be high enough for a magneto installation is oftentimes sufficiently low to cause the operation of the sensitive relays in the common-battery system and to cause false signals to be transmitted to the operators. The principal troubles which occur on substation lines may be usually classified under one of the following heads: Grounds; crosses with other lines or with power circuits; open lines and short-circuits. It is the duty of the wire chief to locate these troubles as quickly as possible and arrange to have them immediately cleared.

For facilitating this work a testing desk is provided in the central office, the testing apparatus being arranged more or less in accordance with the circuits shown in the diagram of Fig. 1. This diagram shows the arrangement of a single test circuit, the number of such circuits depending upon the size of the office and the force employed. The testing lines are usually terminated in a cord and plug at the wire chief's desk, from which point lines terminating at the desk in jacks lead to one of the switchboard positions where they are terminated in a cord and plug. The position on which these lines are placed is connected to the wire chief's talking set by means of a calling circuit, so that at any time the tester may get into communication with the switchboard operator and have any desired subscriber's line connected on any test line leading to the desk.

In addition to these lines, connection is made from the jacks in the wire chief's desk to plugs or clips located at the main distributing frame, so that the outside lines may be tested directly from their point of entrance to the building without the necessity of testing through the switchboard. Referring again to the diagram, key No. 1 has its outside springs connected to the generator which furnishes the ringing current for the exchange. The operation of this key serves to throw the non-grounded side of the ringing generator in connection with the ring conductor of the plug, thus enabling the tester to signal either direct lines or the "A" parties on a two-party line. Key No. 2 is so connected in the circuit that its operation connects the non-grounded side of the ringing generator to the tip strand of the plug and thus serves to ring the other party on a two-party line. Key No. 4 is a reversing key and serves to reverse the connections of all the remaining keys in the test circuit. Key No. 5 is used for throwing a ground on either side of the line for testing purposes when operated in connection with the reversing key. No. 6 in the same way connects the voltmeter to the line to be tested, and No. 7 connects the relay to the line.

Where it is desired to throw ringing current on a line for a considerable length of time, either for the purpose of enabling a lineman to locate a particular conductor or to attempt to raise a subscriber who fails to answer his telephone, key No. 8 is employed. This key, known as the continuous ringing key. is connected to the ringing generator and when used in connection with the reversing key. the current may be thrown at will on either side of the line. Key No. 3 is for listening purposes and in operation bridges the wire chief's talking set across the test cord and enables conversation to be carried on with the operator or with the subscriber whose line is being tested. No. 10 is the retardation coil key and is used by the wire chief when answering calls from the switchboard. The operation of throwing this key bridges the 600-ohm retardation coil across the line, and by operating the supervisory relay in the connecting cord circuit extinguishes the supervisory lamp, thus notifying the operator that the connection has been taken up. Upon the completion of the conversation, the key is returned to its normal position and the supervisory signal in the cord circuit lights, showing the operator that the connection is completed.

The repeating coil key, No. 9, is used for connecting the repeating coil in the talking circuit when the wire chief is connected to a magneto line or toll line. The battery key, No. 11, is utilized in connection with No. 9 for furnishing battery current to the repeating coil. The testing voltmeter is wound with two windings, one to give readings over a 40-volt scale and the other over a two-volt scale. Keys 12 to 16 inclusive are used in connection with the voltmeter, as will be explained later in detail.

The simplest method of testing a line for ground consists in using the relay and sounder; this is accomplished by connecting the test plug to the line and throwing key No. 6 so that the outside springs are brought into contact with the long springs of the key. Current will then flow from the 24-volt battery out over the tip of the testing plug and the line. If a ground be on the tip side of the line, the return circuit will be completed and the relay will operate and in turn operate the sounder, notifying the tester of the existence of the ground. Should the line show clear on this test, the reversing key (No. 4) should be thrown and the test applied to the ring side of the line. While this method is a convenient one for locating the existence of such a trouble, it gives no indication of the location of the ground and can, therefore, be considered only as a preliminary test. The chief use of the relay and sounder is, however, not so much in locating grounds which are outside of the central office, but in enabling the tester to trace out lines in the office itself and in giving an audible signal when a ground is thrown upon a proper line.

For the accurate location of line grounds the voltmeter must be resorted to, and in this connection the two scales and the shunts play an important part. By means of the reversing key the voltmeter may be connected in series with either side of the line and either 40-volt or 2-volt testing current be sent through it. The degree of accuracy which it is desirable to obtain

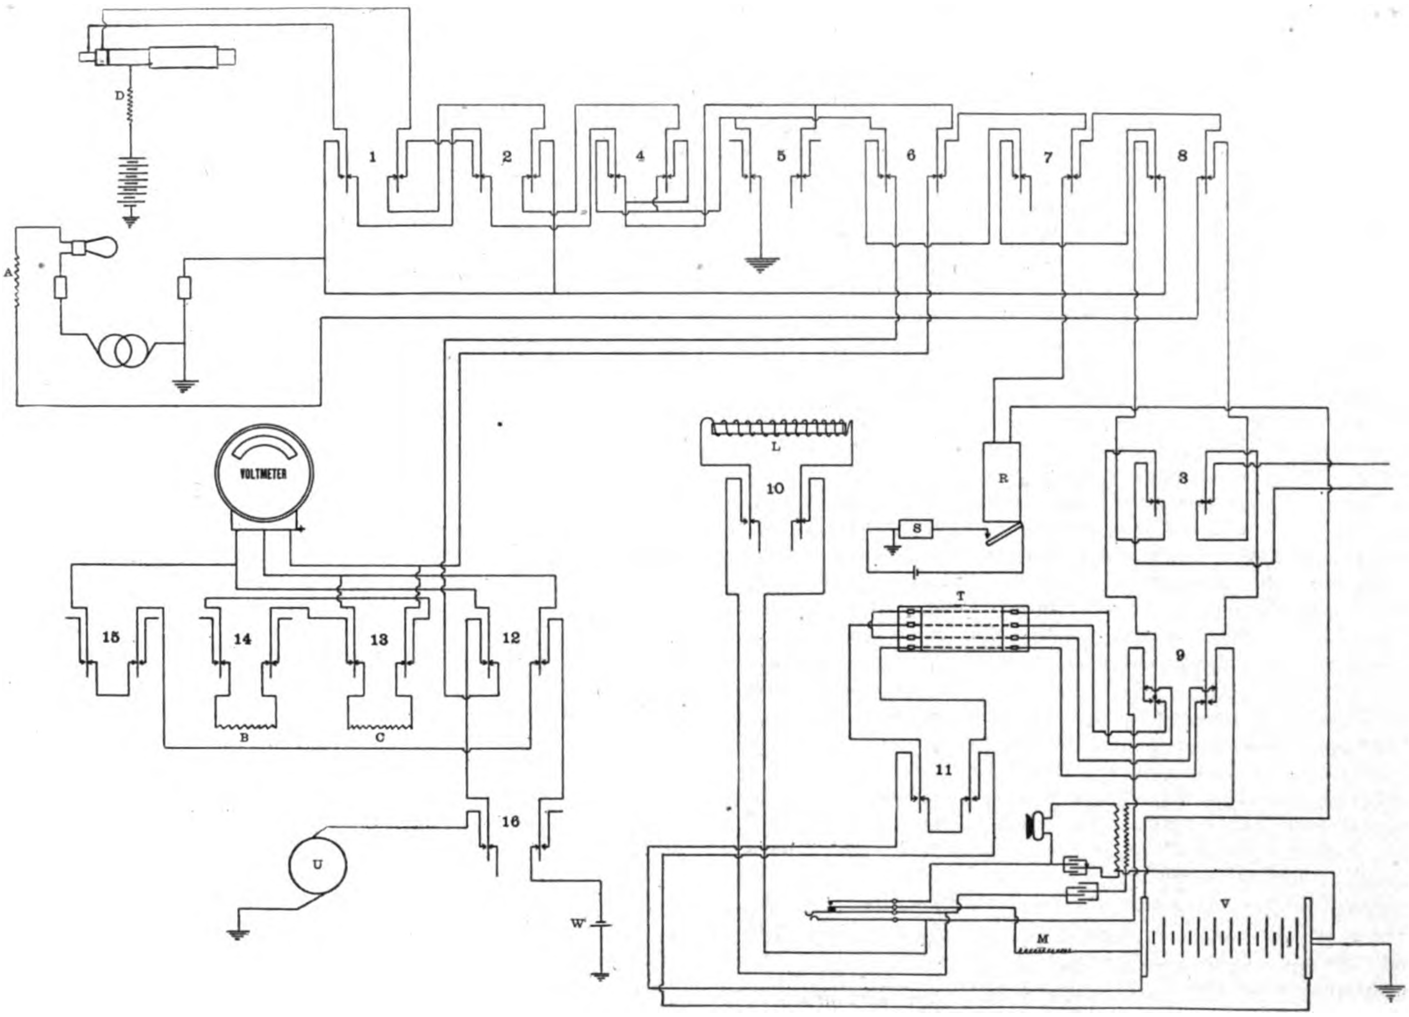

FIG. 1.—DIAGRAM OF CONNECTIONS FOR TELEPHONE TESTING EQUIPMENT.

in locating the trouble determines which of the two testing batteries and voltmeter scales shall be used. If it is desired to use the 40-volt current, it is thrown on the line through the voltmeter by operating keys 16 and 12, this serving to connect the voltmeter and battery in series with the tip side of the line; the further operation of the reversing key connecting the combination with the ring side of the line. If there is a ground, the voltmeter, when connected in this way, will show a reading representing the drop in voltage as the current passes through the instrument. Knowing the resistance of the voltmeter and the voltage of the testing battery, the current which passes through the voltmeter can be calculated from the formula

$$E = IR,$$

where E represents the drop or the reading of the voltmeter, I the current passing through it, and R the resistance of the instrument. The value of the current is, of course, the same at every point in the circuit from the testing battery to the ground on the line, and knowing the current flowing and the voltage applied, the total resistance of the circuit may be readily calculated by means of the formula

$$I = \frac{E}{R}, \quad \text{or} \quad R = \frac{E}{I}.$$

The resistance of the voltmeter being subtracted from this result gives the resistance of the line, including the resistance of the ground, which in ordinary cases may be neglected. From this result the tester, knowing the length and route of the line under test and also the size and resistance of the line conductors, is able to estimate very closely the location of the fault and to give the trouble man sent to clear the ground intelligent data as to where to look for it.

The use of the two-volt battery and scale in testing enables more accurate results to be obtained, as the 2-volt scale may be read with a much greater degree of accuracy than the 40-volt scale. This accuracy may be further increased by the use of the voltmeter shunts, which serve to deflect a portion of the current around the voltmeter. As will be noticed in the diagram, the 40-volt winding of the instrument may be short-circuited or entirely cut out by the operation of key No. 15.

In testing the line for a cross the voltmeter should first be connected to one side of the line, the other side being grounded; the conditions should then be reversed, the reading in both cases being the same. If the cross is of low resistance, as is often the case in troubles of this kind, the distance from the exchange may be readily calculated by means of the formulas given, remembering in the calculation that the line resistance obtained represents twice the length of the conductor from the central office. When a common-battery line in its normal condition is tested by connecting a voltmeter and testing battery in series with it, the voltmeter will show a momentary deflection due to the capacity of the line and the condenser which is bridged across it at the sub-station. In the average exchange, where the subscribers' lines radiating from it are of practically the same length, the deflections thus obtained for the various lines on test will be approximately equal. This feature provides an excellent method for at once ascertaining the existence of an open line, as the absence of the customary condenser reading when the voltmeter is connected to the line indicates an open line; and by operating the reversing key it may be determined whether one or both sides of the line are open. On long lines, even an open line will show some momentary deflection when under test, the deflection being due, of course, to the capacity of the line. The location of the break in cases of this kind is a matter of experience in gauging the voltmeter deflection. In offices having in addition to local substation lines trunk lines which are of considerable length, it is of great importance to include a milliammeter in the wire chief's testing equipment to be used in testing for grounds, crosses and short-circuits on the toll lines, as a much greater degree of accuracy can be obtained in this way than is possible with the use of the voltmeter. Under usual conditions, the tests described are made through the multiple switchboard, but as previously mentioned, provision is made so that the wire chief may, by removing the arresters at the main distributing frame, test directly from that point out on the line, or make his test to include only that portion of the line which is in the exchange itself.

There are numerous instances which arise in practice where breaks occur in the line wires or in cables where the open line is insulated from the ground and other conductors, and in such cases the only possible method of locating the source of trouble is by means of capacity tests. It not infrequently happens in cases of crosses and grounds that the source of trouble itself possesses considerable resistance. When this is the case, the voltmeter method of testing leads to erroneous results regarding the location of the trouble, and in order to correctly determine the point to be looked after it is necessary to make use of a Wheatstone bridge, locating the fault by means of the "Varley loop" test: or if a bridge is not available, the Murray loop test and a resistance box may be employed. Where the trouble is in a cable, one of the two latter methods is necessary in order to locate it satisfactorily, as inspection in this case will avail nothing. In the case of an open wire line, however, it is at least advisable, where the trouble cannot be located by the ordinary test, to patrol the line and attempt to locate it by inspection, and this can usually be satisfactorily accomplished. Where bare copper line wire is used for open wire lines, there is, as a rule, no difficulty in locating these faults. This does not always apply where insulated conductors are used, as numerous cases have arisen in the experience of the writer where the insulation has remained intact while the conductor itself was broken: this class of troubles will usually prove difficult to locate.

There is one class of faults to which a telephone line is liable, that probably occasions more trouble to the testing force than any other difficulty with which they are called upon to deal. These troubles may be classed under the head of "swinging" or "intermittent" faults and may be due to a number of causes. The swaying of the line wires in the wind may often cause temporary crosses; the continual rubbing of an insulated conductor against a tree may result in the destruction of the insulation to a sufficient extent to produce a ground on the line, this being particularly apparent in wet weather and appearing and disappearing with the movement of the wire; improperly soldered joints, or rosin joints as they are usually termed, are also a source of considerable annoyance and are often difficult to locate.

The troubles which occur in the central office itself do not, as a rule, admit of location by test from the wire chief's desk; this is readily accounted for by the small resistance and capacity which the interior lines possess and the consequent necessity of extreme accuracy of the testing methods employed. It is usually not a difficult matter to determine the exact nature of the trouble which exists on the line in an exchange, but the actual location of such faults can only be determined by inspection and trial. As an instance of the peculiar class of troubles which may be met with in the central office, it may be of interest to cite a case which came under the writer's observation some years ago. As is well known, the operators' positions are connected by means of supervisory taps to listening jacks, which are placed in the manager's, monitor's and chief operator's desks. The usual method of making these taps is to run a pair of wires from the secondary side of the operator's talking set to a pair of lugs on the intermediate distributing frame, and from this point to cross-connect these leads to lines leading to the desk jacks. In the case in question, an operator's position was reported as being out of service and a trial developed the fact that the primary side of the operator's set was in perfect condition. No trouble could be located in the secondary portion of the circuit, and yet a test showed that a short-circuit existed. Upon disconnecting the supervisory lead to the intermediate frame, the circuit tested clear, and the trouble was removed. An investigation of the lines from the intermediate frame to the various supervising jacks was then made, and in the jack at one desk was discovered a small piece of lead which had been broken from the point of a pencil. This being removed and the cross-connections re-established, the position tested in good condition and the trouble disappeared. The explanation of this case is, of course, a very simple one. A monitor operator had, while sitting at her desk, broken off the point of her pencil in the jack, and considering it of no consequence, allowed it to remain. The lead of course formed a conductor between the jack springs and short-circuited the secondary of the operator's set. It will be apparent from this instance that there are times when troubles arise in central office apparatus which the most elaborate series of tests will fail to explain. In large central offices the testing equipment is usually arranged in duplicate and installed in a two-position testing desk in order that two men may be able to test at the same time. In addition to the testing equipment, the desk is built to contain a filing case or drawer in which are kept card records of the subscribers' lines entering the exchange. The filing case is usually so arranged that the tester has easy access to the line cards while testing. The line records which are shown upon the card contain all the information regarding the line that it is necessary for the wire chief to know, such as the name and address of the subscriber, the cable conductors and cable by which the line leaves the exchange, the jack and panel on which the line terminates in the office, the point at which the line changes from cable to an open wire line, and the route which the line follows; also information regarding the poles, cross arms and pins on which the line is carried, and the terminal pole or distributing box from which the line is led to the sub-station. With this information and knowing the size of the conductors in the cables and in the open wire line, the wire chief is able to gauge accurately the result of his tests and to tell approximately the pole or manhole near which a specific trouble exists. As previously stated, line troubles which are internal to the office are not amenable to the ordinary methods of testing. A successful inside trouble man depends to a large extent upon his intimate knowledge of the location of the equipment and also upon his knowledge of its weak points. To see some of these men at work, an observer would almost imagine that their rapid location of the source of trouble was due to instinct, and to a certain extent this is undoubtedly true. The inside troubles may be divided into grounds, crosses, opens, short-circuits and relay adjustment, the latter trouble being one that is difficult to remedy with some types of telephone relays, unless placed in the hands of an experienced man who is skilled in that sort of work. A peculiar feature which affects the operation of central offices of this type is the great number of false signals that are conveyed to the operators after lightning storms. These signals are the result of the passage of a portion of the lightning discharge through the carbon arresters in the line to ground, the current carrying with it a sufficient amount of carbon dust to connect the grounded and non-grounded carbon and to throw a permanent ground connection on the line. This results in the operation of the line relay and the consequent illumination of the line signal. In the majority of instances troubles of this kind can be cleared by the operator, who inserts a plug in the line jack and rings over the line.

The method of clearing troubles in the cord circuits and the description of the automatic plugging up line, both of which constitute a part of the wire chief's testing equipment, have been described in recent issues of this paper and for that reason are not given in detail here. The efficiency of any arrangement of testing circuits in practical use is so thoroughly dependent upon the personality of the man at the testing table that it is a difficult matter to say just what testing arrangement is the best. The circuits described herein, however, have been used to a considerable extent and have proven themselves entirely adequate to meet the demand.

There is one feature in connection with the maintenance of a central office which comes directly under the jurisdiction of the wire chief, having a far-reaching effect upon the trouble record; that is, the question of soldering and soldered connections. The telephone current is very small and it is diminished rapidly by resistance in the line, and the effect of a poorly soldered connection is often of a serious nature, so far as the operation of the line is concerned. To insure satisfactory work in this respect, it is absolutely necessary that the soldering irons should be kept clean, that their points should be kept well tinned, and that the contacts to be soldered should be clean and free from grease. If these precautions are observed satisfactory joints will be the result and the troublesome rosin connection will be conspicuous only because of its absence.

◆

PUMPS IN CENTRAL STATIONS.

BY W. T. EDWARDS.

When estimating the head against which a pump is expected to work, the height should be taken from the surface of the supply to the discharge nozzle; thè location of the pump above the source of supply having nothing whatever to do with the calculations, the vertical distance between the two points mentioned being the head regardless of the bends that the discharge pipe may make. The power required to force water to a given height depends principally on the head just described, and in addition thereto account must be taken of the friction in the pipes, bends and valves. Increasing the head 15 per cent will usually be found sufficient to compensate for the losses due to friction in the pipes, bends, etc.

The power required to force water to a given height depends on the quantity of water required per minute and the height to which it is desired to force it. Suppose, for instance, that it is desired to deliver 1000 gallons of water per minute to a height of 100 feet; what horse-power will be required? The weight of water is 8.33 pounds per gallon at 62° F. Adding 15 per cent to the head to compensate for friction, results in a height of 115 feet; 33,000 pounds raised one foot a minute is the value of a horse-power, so that in this case the horse-power required will be,

$$H.P. = \frac{1000 \times 8.33 \times 1.15}{33{,}000} = 29.$$

Stated as a general rule the horse-power required to raise a given amount of water to a definite height is equal to the weight of the water discharged per minute times the vertical height in feet, divided by 33,000, or, stated somewhat differently, the horse-power required is equal to the area of the water piston in square inches times the water pressure per square inch times the piston speed in ~~feet per~~ minute, divided by 33,000. These rules are applicable to any of the various kinds of pumps; in fact, they can be used to determine the horse-power required to raise water a given height regardless of the agent used.

In most pumps the steam piston is of larger area than the water piston or plunger; the increase in area being from 25 to 50 cent for ordinary pumps, three times for fire pumps, while for hydraulic pressure pumps the ratio depends on the ratio of the steam pressure to the working pressure. This latter ranges from 500 pounds per square inch to 5000 pounds per square inch for special work. In any case, the product of the area of the steam piston in square inches multiplied by the steam pressure in pounds per square inch equals the product of the area of the water piston in square inches multiplied by the water pressure per square inch. This leads to another method of determining the horse-power of a pump which may be written

TABLE I.—Height in Feet to Which Water is to be Raised.

Gallons per minute.	10		20		30		40		50		100		150		200		300		400

400	1.000	1.150	2.000	2.300	3.000	3.450	4.00	4.600	5.000	5.750	10.000	11.500	15.00	17.250	20.00	23.00	30.00	34.50	40.00	46.00

thus: *H.P. = steam pressure per square inch × piston speed in feet per minute, divided by* 33,000.

There is a loss of power aside from the loss due to friction of moving parts in pumps, by which the power developed in the steam end cannot be reconciled to the quantity of water delivered under a certain head. There is a percentage of loss in the actual delivery compared to the calculated delivery as determined by the displacement and piston speed. These losses are due to faulty design of valves which are of such size or shape as to prevent the free passage of water into the pump barrel so as to fill it completely before the return stroke of the piston or plunger. High speed is also conducive to large loss, as the valves do not have time to become seated before the return stroke, thus allowing water to remain in, and return back into the cylinder. This loss is called slippage or pump slip, and is sometimes considered to be as large as 15 per cent of the calculated discharge; though in well-designed pumps it should not be more than 5 per cent.

TABLE II.—Pressure per Square Inch into Feet Head of Water.

Pounds per sq. in.	Feet head.	Pounds per sq. in.	Feet head.	Pounds per sq. in.	Feet head.
1	2.31	40	92.36	170	392.52

15	34.63	130	300.16	375	865.89
20	46.18	140	323.25	400	922.58
25	57.72	150	346.34	500	1154.48
30	69.27	160	369.43	1000	2308.

Table I gives the theoretical horse-power also the horse-power allowing 15 per cent for friction, etc., that will be required to raise different quantities of water to different heights. Table II gives the pressure in pounds per square inch for various heads or heights of columns of water. Table III gives the equivalent pressure per square inch for various heads of water in feet. Table IV shows the quantity of water in gallons actually discharged per minute by pump cylinders of diameters from 2 inches to 20 inches and a piston speed of 100 feet per minute.

In calculating the size of pumps required for boiler feeding, a simple rule easily remembered is that one gallon per minute of theoretical discharge will supply water for 10 boiler horse-power, and a circulating-pump will be required to supply from 30 to 50 gallons for each gallon supplied by the boiler feed-pump.

The piping system to a pump should receive very careful consideration in order that the pump should work with the best efficiency. With this end in view, care should be taken to have all joints absolutely air tight; all bends should be of large radius, and their number as small as possible; the run should be as short as practicable and no needless valves should be used. This last, aside from the benefits to the working of the pumps, should be considered from an economical standpoint, as it will have a material bearing on the cost of installation. The greatest natural pressure that can be employed to get water into the pump is 14.7 pounds per square inch. This pressure cannot under any circumstances be increased so that it is extremely desirable that the friction in the suction pipe be reduced to the lowest possible amount so that pumps running at high speed will be able to get as much water as can be handled by the pistons at the given speed. This is accomplished by having the suction pipe of a size that will keep the velocity of water at not over 200 feet per minute. This speed is about that at which pumps give the best service and is obtained where the suction pipe is not more than 25 feet in length; when this length is increased the speed should be decreased, depending on the length of the suction pipe. The suction pipe should be of uniform diameter from end to end; enlargements should be avoided as they interfere with that uniform rate of flow so essential to the proper filling of a pump. If the suction pipe, from any cause, has to be made larger than the inlet to the pump, a conical piece of pipe should be used and attached directly to the suction flange of the pump or as close to it as possible. It should have a continuous and uniform rise from the water level of the supply to the pump. Any irregularity in laying which would tend to form air pockets in the pipe must be avoided if good results are to be expected. Should the supply be taken from a pond it is well, if possible, to have the horizontal run of the pipe laid below the surface of the supply, the vertical lift coming directly at the pump; by this arrangement most of the suction pipe is always under water and liability to air leakage is eliminated. Where the suction pipe is placed under ground nothing but cast iron pipe, flanged together, should be used. In laying the suction pipe, as well as in making up all lines of pipe, steam or water, care should be taken so that no foreign matter gets into the pipes, such as sand, iron chips, scale, bolts, nuts, etc.; such materials cause a great deal of trouble.

TABLE III.—Feet Head of Water into Pressure, per Square Inch.

Pounds per sp. in.	Feet head.	Pounds per sp. in.	head. Feet	Pounds per sp. in.	head. Feet
1	.43	60	25.99	200	86.62
2	.87	70	30.32	225	97.45
3	1.30	80	34.65	250	108.27
4	1.73	90	38.98	275	119.10
5	2.17	100	43.31	300	129.93
6	2.60	110	47.64	325	140.75
7	3.03	120	51.97	350	151.58
8	3.40	130	56.30	400	173.24
9	3.90	140	60.63	500	216.55
10	4.33	150	64.96	600	259.85
20	8.66	160	69.29	700	303.16
30	12.99	170	73.63	800	346.47
40	17.32	180	77.96	900	389.78
50	21.65	190	82.29	1000	433.09

The suction pipe should be absolutely tight; about this there should be no question, as upon the tightness of the pipe depends the efficiency of working if not successful operation of the pump. Should the pipe leak it must be tested, joint by joint, until the leaks are discovered. To do this the pipe must be laid bare, even though it has been buried in a trench. A good, practical way to test a pump for leaks is to blank off the suction pipe and the discharge end with blank flanges, then fill pump and suction pipe with water. Insert in some convenient place on the suction pipe a pressure gauge, and with a small hand force pump create a pressure of 40 or 50 pounds per square inch; then shut off the force pump connection with the pipe and pump and watch the pointer on the pressure gauge. If the pressure falls there is a leak, and if the pipe be accessible throughout its length the leak can readily be found when the pump is in operation by the hissing sound of the air rushing into the pipe. The exact location of the hole may be found by holding a lighted match or candle to the place, the movement of the inrushing air deflecting the flame toward the hole in the pipe.

A strainer should be placed in the suction pipe to keep out foreign matter, such as fish, twigs, leaves, etc. This should preferably be placed at some accessible point. When placed at the submerged end of the suction pipe it cannot be conveniently reached. There is, however, a make of screen, now on the market, that can be raised from its position at the bottom of a suction pipe, cleaned and returned.

SOME HINTS ON CONDUIT WORK.

BY T. F. M'MACKIN.

The installation of iron pipe conduit in non-fireproof factories or buildings is quite common, and the number of buildings to be thus equipped is ever increasing. In the present article, however, this class of building will not be considered; instead, some points in the installation of conduit in fire-proof structures will be taken up and illustrated.

Practice has proved that in fire-proof structures, iron pipe conduit can be used where it is impossible to run cleats, porcelain or even bare wires. By way of illustration the writer has in mind a newspaper office in this city. The building had been used a sub-station for a street railway company, and when vacated by the railway company was remodelled into an office building. Naturally the building was of fire-proof construction, with terra-cotta floors and wrought iron frame work. To make a finished ceiling wire lath was installed and covered with plaster.

TABLE IV.—Discharge of Pumps with a Piston Speed of 100 Feet per Minute.

Diameter of cyl's in inches.	Theoretical discharge in gals.	Discharge allowing 15% for slippage.
2	16.32	13.87
4	65.28	55.48
6	146.90	124.86
8	261.10	222.00
10	408.00	346.80
12	587.50	499.37
14	799.70	679.74
16	1044.00	887.40
18	1322.00	1123.70
20	1632.00	1386.20

For the lighting system, main feeders were run from the main switchbox in the cellar to a switchbox located on the east wall of the ground floor of the building, entering the same from the bottom. The different lighting circuits were run from this distributing board in ½ in. iron pipe conduit, six to twelve lights being carried on a single circuit. The points requiring lights were in the center of arches so that girders or I beams were not available.

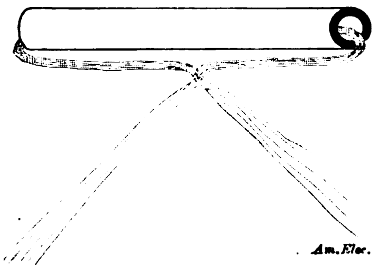

FIG. 1.

A primitive method of securing conduit to a wire lath ceiling is illustrated in Fig. I. A small ¼-in. nipple 3 ins. long has several fine copper wires run through its bore and these are twisted together at the center. A small hole is cut in the ceiling and the nipple is driven in upright past the lath. A sharp pull downward serves to adjust the device and two men hold the conduit while a third draws the loose ends around the pipe and fastens them at the bottom by twisting. To obviate this makeshift and at the same time provide a more permanent device, a little adjustable bolt, known as a toggle bolt and shown by Fig. 2 herewith, was introduced. This is made in two parts, a rod or bolt and a plate attached thereto. The construction is clearly shown in the engraving, but several other forms of toggle operating on the same principle are on the market. The plate is held in a vertical position when being installed in the ceiling, and as soon as the end clears the upper side of the lath or fireproof brick as the case may be, the plate, owing to one end being heavier than the other, assumes a horizontal position. These toggles are generally used to fasten the conduit boxes in place. The boxes support the conduit pipes which run from outlet box to outlet box, entering same a distance of about ½ in.

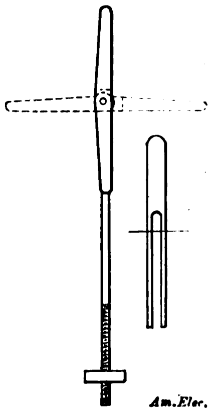

FIG. 2.

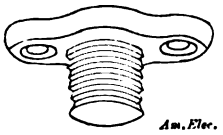

FIG. 6.

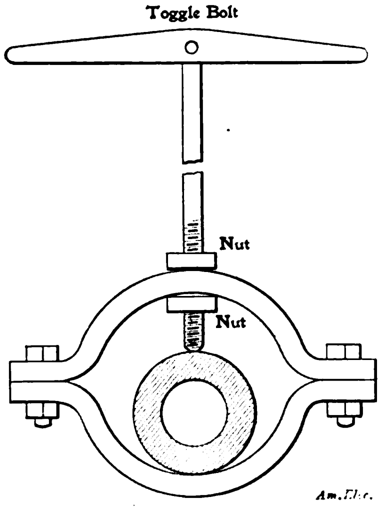

FIG. 3.

When long runs are required and the conduits run 6 or 7 ins. below the ceiling, special hangers must be attached to the lower end of the toggle bolt. To show how easily this may be accomplished reference should be made to Fig. 3. Here two ordinary ½-in. galvanized iron pipe straps are employed, a small hole being either drilled or punched in the center to admit the end of the toggle bolt. Short flat head bolts and nuts ⅛ in. in diameter hold the two straps together, and lock nuts are provided to hold the combination in position as well as the conduit which rests in the lower part of the hanger. If it is desired to have the job present a neat appearance, the exposed part of the toggle may be encased in a ¼-in. nipple which should be long enough to make a tight fit from the upper strap to the ceiling.

The device shown in Fig. 3 serves very well on a single pipe, but where four or five conduit lines are to be accommodated some other means must be provided. Fig. 4 shows a simple hanger for this purpose. In the case under discussion the conduits were two feet lower than the ceiling so that extra long toggle bolts had to be used. A wrought iron bar having a ¼-in. hole at each end is slipped over the rods and held in place by two small nuts. In this manner both of the toggle bolts are connected together and thus support the conduits. In passing under wrought iron beams, a thin piece of band iron with hooked ends is fastened to the girder or beam, the band iron running in the same direction as the conduit or circuit. The conduit is fastened to this band iron by means of a short piece of No. 12 galvanized iron wire. The long rods mentioned above have a 1¼-in. piece of gas pipe covering the exposed parts.

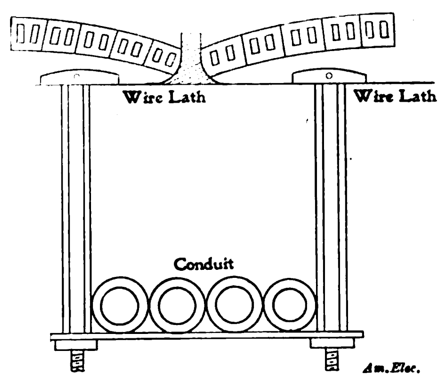

FIG. 4.

Fig. 5 shows the cluster light attachment. The conduit boxes used are round and flat on top and bottom. Five holes ⅝-in. in diameter are provided in the back and four holes equally distant from each other are provided in the side. These holes are covered with blind iron washers held in place by a preservative or insulating compound, and whenever an opening is desired one of these washers is knocked away or forced out with a hammer. The wires are bared and two extra lengths of wire spliced thereto in accordance with the rules of the National Board of Fire Underwriters. A special cover and short piece of pipe are provided. A fixture support, Fig. 6, is made fast to the back of the box and an insulated joint is made on the threaded portion of the fixture lug, one wire being passed through a small opening or slit in either side of the joint. The short length of pipe is fastened to the lower end of the fixture support and a combination socket is provided accommodating from 3 to 5 lamps with an opalescent shade. Short saddle bends were made where one pipe had to pass over another. Toggle bolts were used to fasten the switchbox to the side of the wall; one in each corner and one in the center of the box. The installation was neat in appearance and at the same time not very expensive.

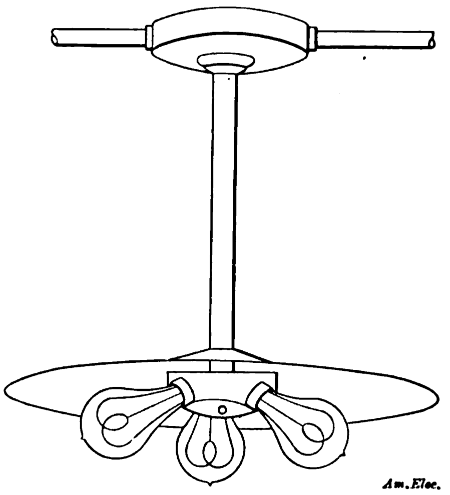

FIG. 5.

Greenfield tubing is used on many jobs where economy is practiced. This is a flexible tube composed of iron or steel wound or twisted about a soft metallic inner core. It is much easier to run than conduit pipe; but care must be exercised in fastening the tubing to the boxes. The necessary length of tubing is cut off with a hack saw, the tubing running from outlet box to outlet box. To fasten it securely to the box a special coupling (Fig. 7) or clamped fitting is provided. One end fits over the tubing and is clamped thereto with a screw. The other end has a female thread accommodating a chased nipple. These fittings are of brass and used only at outlet boxes. This idea is not generally known; but the

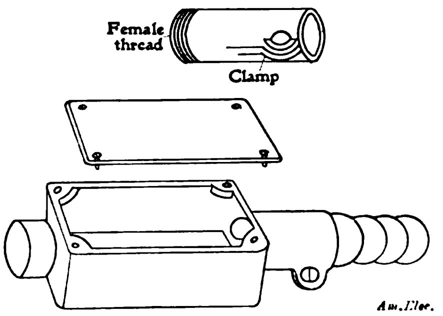

FIG. 7.

customary method of attaching an iron collar to the end of the tubing after it enters the box is also followed. Iron pipe conduit work stands in a class separate from all other branches of work in the electrical trade. Skill and taste are required in installing it and many electricians who cannot work on the line show great facility in this class of work and vice versa.

Lessons in Practical Electricity

THE ROTATING MAGNETIC FIELD.

Like the currents which produce them, magnetic fluxes due to alternating currents have phase relations. If two coils of wire be mounted on a single core and two currents, differing in phase, be passed through the coils, the magnetic flux set up in the core will be the resultant of the two fluxes that would be set up by the two coils separately. Thus, if the currents were equal in strength but differed in phase by a quarter of a cycle (commonly termed 90°), they could be represented graphically by two vectors of equal length 90° apart, as shown in Fig. 1. The fluxes that would be set up by the coils separately could also be represented by the same vectors, since the magnetic lines of force rise and fall in the same way as the current that produces them. The resultant of the two fluxes, therefore, may be plotted graphically by combining two vectors each representing one of them, the two being given the phase relation corresponding to that of the magnetizing currents; this combining of vectors is illustrated in Fig. 2 and was explained in the preceding lesson.

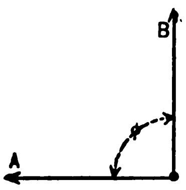

FIG. 1.

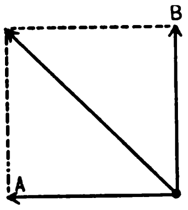

FIG. 2.

For a practical example, suppose two coils to be wound on an armature core with their axes at right angles, as indicated in Fig. 3; a current passed through either coil will produce a magnetic flux in the core parallel to the wires of the other coil; when both coils are energized by the same current, the resultant flux is in the direction exactly half way between that of each of the individual fluxes, as indicated in the diagram. (For the sake of simplicity the dotted lines representing the magnetic flux are not carried all the way across the core, but it will, of course, be understood that the flux passes through diametrically.) The strength of this resultant flux may be measured by the parallelogram method, just as the resultant of any two forces is measureable, if the strength of each is known. Thus, in Fig. 3, if the flux set up by each coil separately is 100,000 lines, the resultant flux would be 141,421 lines, assuming the permeability of the core to be constant, because the ratio of the diagonal of a square to one of its sides is 141,421, and this is the relation between the resultant of two equal forces at right angles and either one of the forces alone.

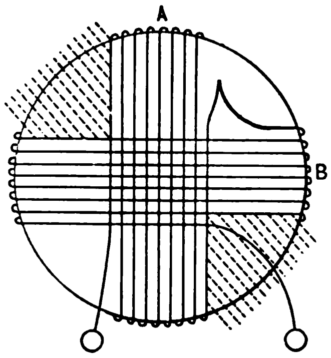

FIG. 3.—TWO COILS AT RIGHT ANGLES, AND RESULTANT FLUX.

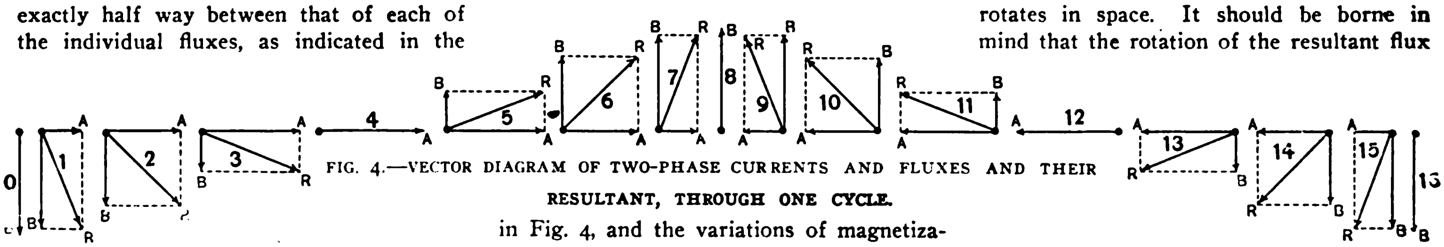

FIG. 4.—VECTOR DIAGRAM OF TWO-PHASE CURRENTS AND FLUXES AND THEIR RESULTANT, THROUGH ONE CYCLE.

Now, if the two windings be separated and energized individually by two currents differing in phase by a quarter of a cycle, a combination effect will be produced. At the instant when the two currents are of equal strength, the resultant flux due to the two coils will be in the intermediate direction shown in Fig. 3; at all other instants the axis of the flux will be somewhere else. This is indicated graphically by Fig. 4, which is a vector diagram of a rotating field produced by two currents a quarter of a cycle apart in phase and passing through two coils mounted with their axes differing by a quarter of a circle (usually termed "differing in mechanical phase" by 90°). When the current in coil *A* is 0, the flux will be produced by coil *B* alone, and its direction will be parallel with the wires of coil *A*, as indicated by the vector *B* in Fig. 4; it is assumed that the direction of the current in coil *B* at this instant is such as to cause the flux to pass from the top to the bottom of the core, as the latter is drawn in Fig. 3. The subsequent variations of the flux-producing ability of coil *B* are indicated by the vertical vectors marked *B* in Fig. 4, and the variations of magnetization due to coil *A* are indicated by the horizontal vectors marked *A*. The lengths of these vectors may be verified by reference to Fig. 5, which shows the two sine waves of magnetism produced by the alternating currents in the two coils, the magnetizing strength of each at each successive 16th of a cycle being indicated by the vertical lines drawn from the 0 line to the curve. It must be remembered that the vertical lines in the upper half of Fig. 5 are changed to horizontal vectors in Fig. 4 because the direction of the magnetizing force set up by coil *A* is horizontal.

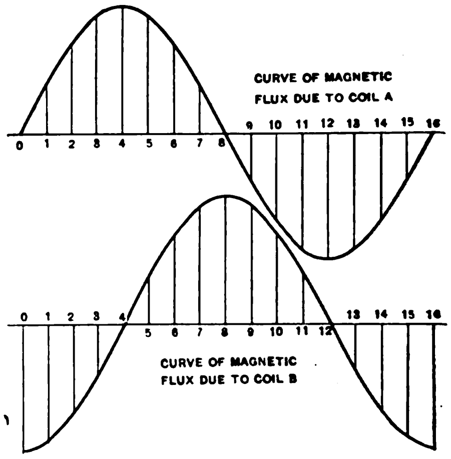

FIG. 5.—TWO-PHASE CURVES.

Returning to Fig. 4, if we assume that the flux set up by either coil alone would be 100,000 lines, and that the permeability of the core is constant so that the flux varies exactly with the strength of the current in the coil, the lines of force that would be produced at each successive 16th of a cycle by coils *A* and *B*, and the resultants of the two, would be as follows:

Increments of cycle.	Coil A.	Coil B.	Resultant flux, 100,000 lines: Angle and direction.
Starting	0	100 000	Vertical, downward.
1st 16th	38 268	92 388	67½° downward, right.
2d 16th	70 711	70 711	45° downward, right.
3d 16th	92 388	38 268	22½° downward, right.
4th 16th	100 000	0	Horizontal.
5th 16th	92 388	38 268	22½° upward, right.
6th 16th	70 711	70 711	45° upward, right.
7th 16th	38 268	92 388	67½° upward, right.
8th 16th	0	100 000	Vertical.
9th 16th	38 268	92 388	67½° upward, left.
10th 16th	70 711	70 711	45° upward, left.
11th 16th	92 388	38 268	22½° upward, left.
12th 16th	100 000	0	Horizontal.
13th 16th	92 388	38 268	22½° downward, left.
14th 16th	70 711	70 711	45° downward, left.
15th 16th	38 268	92 388	67½° downward, left.
End of cycle	0	100 000	Vertical, downward.

Measuring the lengths of the vectors in Fig. 4 would verify these figures if the measurements could be made to the requisite degree of accuracy. It will be observed that although the two fluxes vary from zero to maximum twice in a cycle, corresponding to the variation of the exciting current in each coil, the resultant flux is *not alternating at all*, but remains with a fixed value of 100,000 lines; its axis merely rotates in space. It should be borne in mind that the rotation of the resultant flux is gradual; it does not jump suddenly from one position to the next, as a too literal interpretation of the diagrams might lead a beginner to suppose. The cycle has been divided into sixteen steps merely for convenience and to shorten the discussion of the variation in strength.

The case of the magnetic flux set up by three-phase currents is very similar to the one just explained, but its analysis is not quite so simple. Fig. 6 shows three curves, representing the rise and fall of three alternating currents equal in strength but differing in phase by one-third of a cycle (commonly termed 120°); the individual fluxes set up by the three currents vary exactly like the currents themselves, as already explained, so that the curves may be considered as representing the values of the fluxes. If the three coils producing these fluxes be mounted on a core of constant permeability, as indicated in Fig. 7, a resultant rotating flux of constant strength will be produced, as in the case of the two-phase coils. Having discussed the two-phase arrangements fully, it will not be necessary to follow the three-phase cycle all the way through; one-quarter of a cycle will be sufficient.

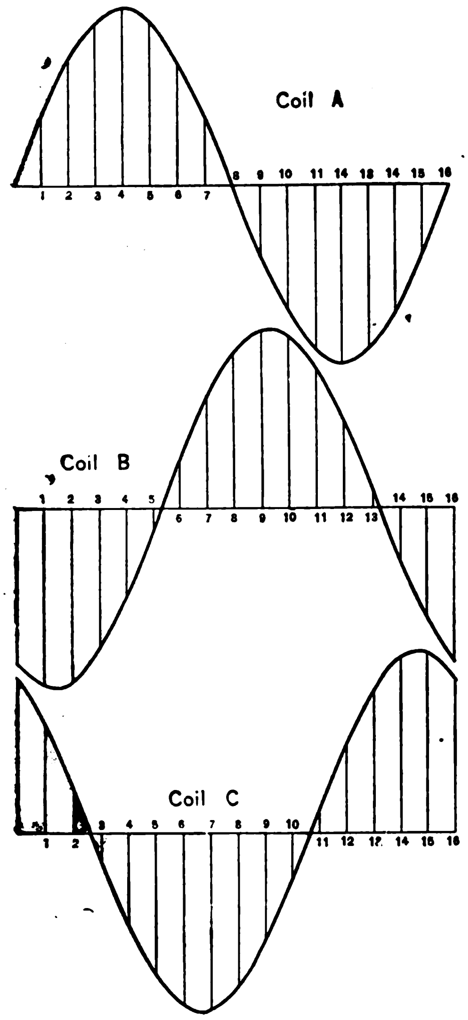

FIG. 6.—THREE-PHASE CURVES.

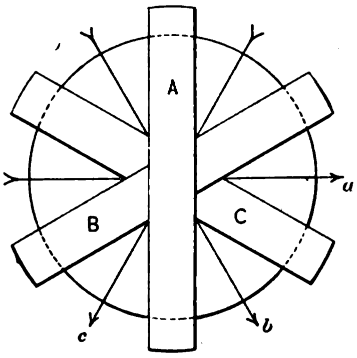

FIG. 7.

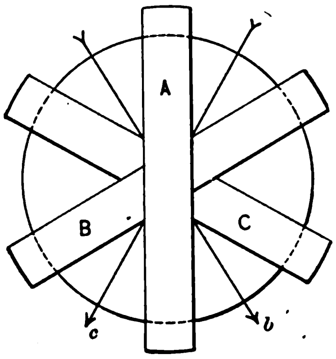

FIG. 8.

We will assume that at the beginning of the cycle under consideration the current in coil *A* is 0; that the current in coil *B* would produce a flux in the direction of the arrow *b* if the other coils were absent, and that the coil *C* would produce a flux in the direction of the arrow *c*, if alone. Under these assumed conditions, which actually occur at the beginning of every third cycle, the resultant flux in the core at the beginning of our cycle will be due to the two coils *B* and *C*; the direction will be downward across the core, parallel to the wires of coil *A*, and the strength of the resultant flux will be the sum of the two individual fluxes multiplied by the cosine of the angle between each individual flux and the resultant. The angle here is 30° and the cosine of this is 0.866; consequently, the resultant flux at the moment of starting the cycle will be 0.866 times the sum of the two fluxes. At this instant each of the fluxes has only 0.866 of its maximum value (see Fig. 6), so that the resultant is 1.732 × 0.866 × maximum individual flux, or 150,000 lines, if each coil alone is capable of producing 100,000 lines of force at the maximum. At the end of the first 16th of the cycle, the coil *A* is producing a flux which, alone, would be 38,268 lines and have the direction of the arrow *a*. The resultant flux is now the combination of the three fluxes, all different in strength. The combination of these by vectors is illustrated by Fig. 9, second position. This diagram gives the strengths and directions of all three fluxes at each 16th of a cycle, through one-quarter of it. The variations through each succeeding quarter of a cycle are exactly the same, excepting the direction of the axis of the resultant flux. From this it will be evident that three currents of equal strength differing in phase by one-third of a cycle and passing through three coils mounted as shown will produce a resultant flux which has a constant strength but rotates in space. It will also be plain that the resultant magnetizing force of three coils and currents of the kinds mentioned is 1½ times that of two coils and currents of the kinds first described, the individual currents and number of turns per coil being equal.

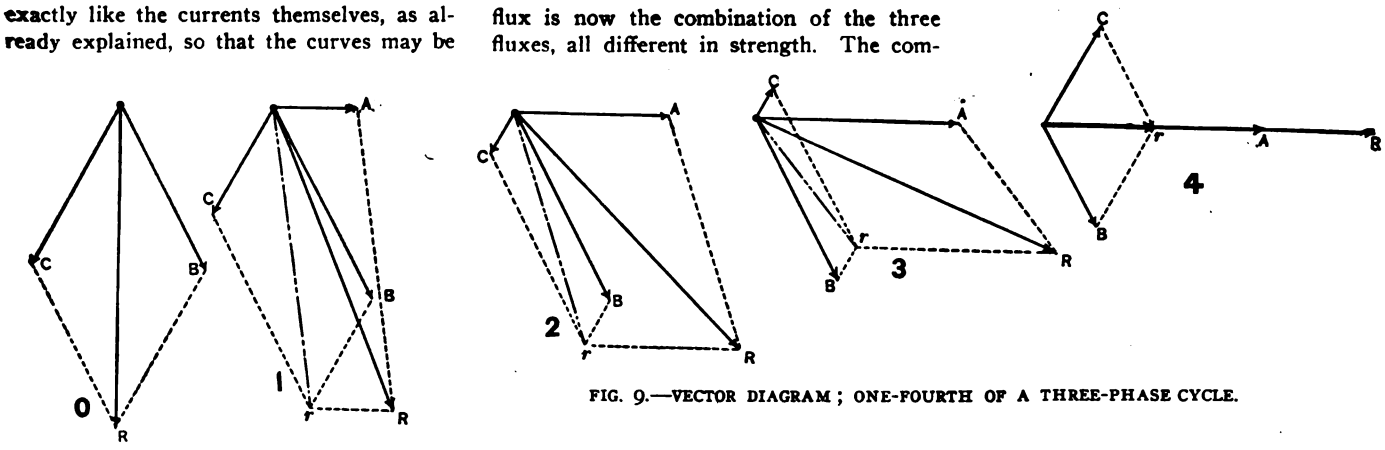

FIG. 9.—VECTOR DIAGRAM; ONE-FOURTH OF A THREE-PHASE CYCLE.

The following fundamental rules will be found useful:

If two or more coils, n in number, be arranged symmetrically about a central point in space and excited by n individual and equal alternating currents which follow the sine law of variation and differ in phase by $1/n$ of a cycle, the alternating magnetic fluxes which would be produced by the coils separately will form a resultant flux of constant strength the axis of which will rotate about the central point.

The plane of rotation will be at right angles to the planes of the coils and the rate of rotation will be equal to the frequency of the exciting currents, 60-cycle currents producing a field which makes 60 revolutions per second, and so on.

The resultant magnetic flux will be equal to $n/2$ times the ***maximum*** flux produced by one of the coils alone, provided the path of the flux is of substantially constant permeability.

Should the currents be of unequal strengths, the resultant magnetic field will not be constant but will vary in strength between $n\,\Phi_a \div 2$ and $n\,\Phi_b \div 2$, Φ_a being the maximum strength of the weakest flux and Φ_b that of the strongest flux. The rate of rotation will also be irregular, the speed of the rotating being greater in some parts of its orbit than in others; the average rate, however, will remain equal to the frequency of the supply currents.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Mr. Notholf's Problem in Motor Operation.

To the Editor, American Electrician:

I submit what I believe to be an explanation of Mr. Notholf's motor problem as published in the November number. Had the 10-h.p. motor been fused with a 20-ampere fuse instead of one of 40 amperes, his trouble would never have occurred. When the 10-h.p. motor became stalled it was equivalent to a dead short on the line, and the time required to blow the 40-ampere fuse resulted in an excessive drop in the line voltage. This may have been caused by the slowing down of the driving power due to the overload, the slipping of the belt for the same reason, or the reduction of generator voltage due to an overload, especially if this were a plain shunt-wound machine. Now the motors being under load naturally slowed down instantly, and this in turn reduced the counter e.m.f. When the 40-ampere fuse finally did blow, the short was removed and the line e.m.f. returned to normal. The motors being under load could not instantly respond to the change and the counter e.m.f. being so much lower than the line e.m.f. a large current flowed through the armatures of the motors; sufficient in fact to blow their fuses. The reason the fuse did not blow on the 7½-h.p. motor, was because the lever of the starting box went to the "off" position when the line voltage went down. Possibly the spring was stronger or the magnet weaker on this starting box than on the others. If the 10-h.p. motor will not run with a smaller fuse than one of 40 amperes, it is evident that it is entirely too small for the work it has to do.

Ironwood, Mich. C. B. SMEETH.

To the Editor, American Electrician:

The curious result obtained by Mr. Notholf is easily explained. The excessive current taken by the stalled 10-h.p. motor, produced an abnormal drop in the line voltage between the generator and the motors. When the fuse blew, the e.m.f. instantly rose again to normal. The other motors meanwhile having slowed down somewhat owing to the decreased e.m.f. available were unable to respond quickly enough and hence took enough current to blow all their fuses, before they would speed up and develop their normal counter e.m.f.

Schenectady, N. Y. ROBERT E. NOYES.

To the Editor, American Electrician:

Referring to the problem in motor operation in the November number, I would offer the following explanation: When the 10-h.p. motor became stalled it was in effect a short circuit on the line which caused a considerable drop in voltage either from overloaded feeders or from inability of the generating plant to meet the demand under these conditions or perhaps both. The low voltage caused the other motors to slow down considerably and as the load on them was a constant quantity which did not decrease with decrease in speed, they had a tendency to likewise become stalled. This would cause an abnormal rush of current in their armatures, blowing their fuses. The starting box of the 7½-h.p. motor may have released from overload or the voltage may have affected the retaining magnet sufficiently to have caused it to release. If the load on these motors had been of such a nature that a drop in speed would have caused a considerable decrease in load as for instance when driving a fan, no overloading would have resulted. The starting boxes would however probably release from low voltage.

New York City. LEWIS C. REYNOLDS.

To the Editor, American Electrician:

Regarding Mr. Notholf's trouble with his motors, I would suggest that the 10-h.p. motor was overfused, and did not relieve the overload promptly, thus drawing an excessive current from the line, reducing the voltage sufficiently in the other branch motor circuits to release the starting box lever on one motor, which may not have had a good magnetic contact, or perhaps, due to its location with respect to the other circuits, the voltage fell to a lower value. The speed of the other motors had so materially decreased before the 10-h.p. motor fuses blew, that when the full voltage came on again, their fuses also blew.

Denver, Colo. LEWIS M. MCBRIDE.

To the Editor, American Electrician:

With reference to the letter of Mr. Harold Notholf in the November number of your paper, I might say that it would appear that the stalling of the 10-h.p. motor and consequently the momentary short circuit or overload evidently caused a drop in the line voltage thereby weakening the fields of the other motors and resulting in an increased armature current beyond the fuse capacity. The fact that the lever of the starting box of the 7½-h.p. motor fell back to the "off" position would indicate an abnormal drop of line voltage. It frequently happens that the fuses of motors when performing work nearly up to their capacity will blow when the line voltage drops to any appreciable extent. It seems to me that this is the only explanation that could be given of Mr. Notholf's trouble.

Kingston, Ont. J. HALLIDAY.

[The author of the above problem has directed our attention to an error made in deciphering his signature, which should be read Harold M. Wolf and not Harold Notholf.—EDITOR.]

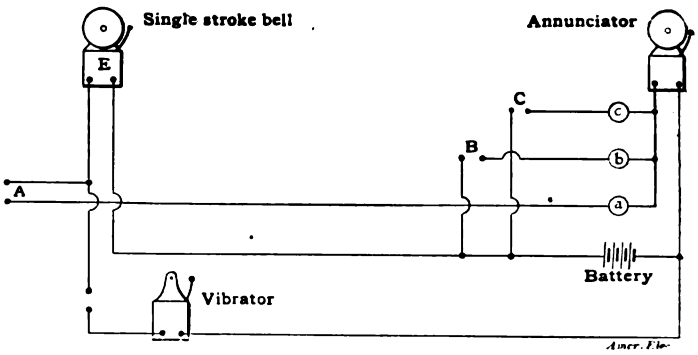
Mr. Remey's Problem in Bell Connections.

To the Editor, American Electrician:

I submit herewith a solution to Mr. Remey's problem in bell connections which appeared in the November number. A vibrating bell with bell removed or a small buzzer and a small amount of wire suffice, so that with the conditions laid down, I cannot conceive of a more practical or economical method of solving the problem. A single wire with the push and vibrator in series is connected as shown by Fig. 1. From this it will be evident that the stroke is single when operated from *A* and vibrating when operated from the push in the basement. The annunciator is not in circuit, so that it cannot indicate or ring.

Cincinnati, O. JAMES T. COBERT.

[Solutions similar to the above were also received from A. E. Ecklund, Pittsburg, Pa.; Richard Gessner, Oak Park, Ill.; C. H. Hodgkins, Providence, R. I., and J. Siddall, Kearny, N. J. We have received a number of solutions calling for an extra battery for the bell *E*, and others in which the bell *E* was arranged as a single stroke and vibrating bell combined. These are all inadmissible.—EDITOR]



MR. COBERT'S SOLUTION TO MR. REMEY'S PROBLEM.

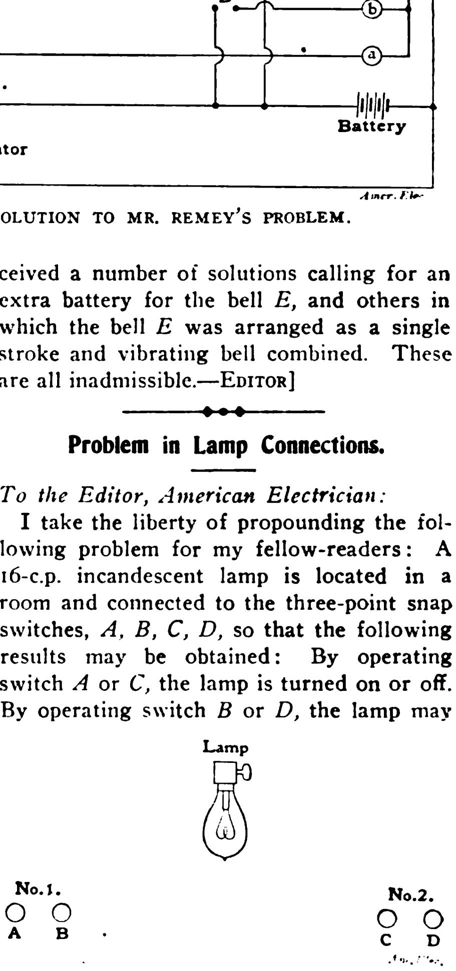
* * *

Problem in Lamp Connections.

To the Editor, American Electrician:

I take the liberty of propounding the following problem for my fellow-readers: A 16-c.p. incandescent lamp is located in a room and connected to the three-point snap switches, *A, B, C, D,* so that the following results may be obtained: By operating switch *A* or *C*, the lamp is turned on or off. By operating switch *B* or *D*, the lamp may be made to burn dimly or brightly, a 32-c.p. lamp being used as a resistance. Whatever is produced at No. 1, the contrary is possible from No. 2. How is the lamp connected?

Birmingham, Mich. L. F. MCHUGH.



PROBLEM IN LAMP CONNECTIONS.

Queries and Answers

IMPORTANT.—No attention will be given to any inquiry which does not give the full name and address of the inquirer.

What is the correct pronunciation of volt, ampere and gauss? H. C. D.

Vohlt, ompair and gowce.

Is there any way to prevent mutual induction and consequent cross-talk between two parallel ground-return telephone circuits without changing the lines to metallic circuits? P. H. W.

No.

How can I obtain violet rays from an arc lamp? (2) Is there any other way to improve an arc lamp for photographic purposes? L. R. M.

By lengthening the arc. (2) We do not know of any.

How should a three-wire circuit be fused to deliver current to 30 enclosed-arc lamps each requiring 5 amperes? W. J. McN.

Put a 75-ampere fuse in each of the three leads, if the lamps are connected 15 on each side of the neutral wire.

What causes the armature of an electric motor to revolve? C. F. H.

The attraction between the magnetic fluxes set up by the field magnet and the current in the armature wires. See the Lessons Department in the September, 1902, number of this paper.

Where can I get castings for the 4-kw. double current machine described in "Electrical Designs"? E. L. B.

We do not know of any source where they can be bought. It was intended that the reader should make his own patterns and get castings made from them.

Please give instructions for making a battery suitable for the treatment of rheumatism. W. G. P.

The faradic batteries commonly used for nervous and muscular troubles can be bought for less than the material necessary to make one would cost you—*i. e.*, from $3 up.

Is there any preference by the Underwriters as to whether service wires should enter a residence in the attic or the basement? Should the main switch, fuses and meter be put in the attic or the basement? C. D. B.

So far as we know there is no preference from the Underwriters' standpoint; we should much prefer putting the entrance in the attic.

I have made the voltmeter described in "Electrical Designs," but cannot get the magnet to hold magnetism; it is made of tool steel and hardened by heating and quenching in sal ammoniac solution. What is the trouble? H. S.

The steel is not of the right quality for permanent magnets; you will have to use either chrome or tungsten steel. The best plan is to have the magnet made by some establishment that makes permanent magnets for commercial purposes.

Where can I obtain castings for dynamos of 5 to 25 incandescent lamps capacity, with instructions for winding the machines? R. K.

We do not know of any source whence such material is obtainable. We are publishing a series of articles which will enable anyone to lay out a design and the windings for it in any size up to 16 ins. diameter of armature; these appear on the pages immediately following the editorial pages of each number.

Which is it more essential to keep steady in an alternator supplying induction motors, the speed or the voltage? (2) What is the relation between the slip of an induction motor and the current taken by it? (3) In a small sub-station supplied from a three-phase circuit and supplying chiefly a lighting load (with a few motors) is it good practice to deliver current to the distribution circuits directly from transformers of the proper transforming ratio? R. F.

The voltage, because the torque of the motors varies with the square of the voltage while the output varies with only the first power of the frequency. (2) The current varies approximately with the slip. (3) Yes.

Please give a formula for estimating the size of wire to be used in an electric heater and one for the probable rise in temperature of the heating conductor. H. H. P.

The size of conductor must be such that its resistance when hot will be equal to the voltage at its terminals divided by the current it is to carry. We know of no accurate formula for rise of temperature; the effective radiating surface varies so widely with different conditions that a general formula cannot be deduced. The only reliable way to determine the temperature rise is by experiment.

What is the resistance of the shunt field winding of a 125-kw. compound-wound generator? (2) Does the shunt resistance bear a fixed relation to the output of the machine? (3) Where can I get a table of conduit pipe sizes to be used for different sizes of wire? W. H. S.

(1) and (2) The resistance of a shunt winding depends on the ideas of the designer of the machine; there is no fixed relation for all machines. (3) There is no such table in print because the outside diameter of a given size of insulated wire varies widely. The internal diameter of the conduit must be large enough to allow the wire to be drawn through it easily.

Will a 4-pole dynamo operate with a 2-pole armature winding and two sets of brushes set at 180 degrees? (2) If not, what are the practical combinations? V. E. H.

No; the brushes would be at points of equal potential on the commutator. (2) The machine will work with the 2-pole winding and four sets of brushes 90 degrees apart, but this will give only half the normal voltage. The armature should be rewound with a 4-pole winding and the brushes arranged to correspond; if it is a small machine, use a two-path winding with two groups of brushes 90 degrees apart; if it is a large machine, use a simple lap winding with equalizing connections and four groups of brushes.

A brine pump supplying three sets of cooling coils will not keep all of the coils down to the proper temperature. The pump cylinder is 5 ins. in diameter, its discharge outlet 4 ins. bushed down to 2½ ins. The delivery pipe is 2½ ins. diameter throughout; the branch for the first coil taps into the delivery pipe a little distance from the pump and the branch to the second coil taps in farther along; the main pipe runs through to the third coil, 30 feet above the pump, and this coil is the one that is hardest to cool. The coils are all of 1½-in. pipe. How can the cooling be made equal in all the coils? W. D. W.

The delivery pipe should be the full size of the original pump outlet up to the second branch pipe junction to avoid throttling the total discharge stream; by throttling with valves the branches to the coils which give the best results, all three coils can be made to cool equally.

Please give data for an induction coil to give a 5-inch spark. (2) What form of interrupter is best for X-ray work? (3) Can the coil be excited from a 110-volt circuit? (4) Will it work if supplied from an alternating-current circuit? R. E. S.

Make the core of annealed iron wires, No. 22 gauge, 12 ins. long, 1⅛ in. diam. For battery work wind the primary with two layers of No. 12 wire wound to cover 11 inches of the core; for 110 volts use four layers of No. 16 wire and put a dead resistance in series with it. Put 7 pounds of No. 36 silk-covered wire in the secondary winding. (2) A mechanically-driven interrupter. (3) Yes; direct current. (4) Not satisfactorily; the reversals are not sufficiently sudden.

What connections should be made to the commutator of the double-current machine described in the March, 1900, number (Chapter X of "Electrical Designs") to make it a combined direct-current and single-phase alternating-current machine? (2) Would the machine give 110 volts direct and 80 volts alternating simultaneously if driven as a generator? (3) Would it overheat if operated as a direct-current generator alone? E. L. D.

Lead four taps out from four equidistant commutator segments to two collector rings; two diametrically-opposite taps to one ring and the other two taps (also diametrically opposite) to the other ring. (2) It will give 110 volts direct and about 70 volts alternating at the same time; the sum of the outputs in amperes on both sides must not greatly exceed the total rated ampere capacity of the mahine. (3) No.

Are machines built commercially to give both direct and alternating currents and to supply a three-wire system balanced with auto-transformers? (2) If so, what is the approximate ratio between the direct-current voltage and the alternating-current voltages? (3) How would the efficiencies compare operating the machine as a straight direct-current generator, a straight alternator and as a combined machine? (4) Could such a machine carry its full rated load as either a direct or alternating-current dynamo? (5) Would an 8-pole machine running at 900 r.p.m. give 60 cycles? (6) How many phases would it give? J. E. McI.

Yes; any rotary converter will do so if driven as a generator by some external source of power. (2) A three-phase machine will give an alternating voltage of about 63 per cent of its direct voltage; a two-phase machine will give about 71 per cent of its direct voltage on the alternating-current side. (3) The highest efficiency is obtained operating as a combination machine; the next highest as a direct-current machine alone. (4) and (5) Yes. (6) The number of phases depends entirely on the armature winding; the speed and number of poles do not affect that.

THE ELECTRICAL TESTING LABORATORIES.

Commercial testing laboratories have been maintained in Europe for the past ten years with marked advantage to the industries availing themselves of them. Need of such an institution has been felt for some time in this country by manufacturers, engineers and purchasers alike, and at one time it was suggested that a laboratory be maintained in New York by one of the electrical societies. Doubts, however, of financial success caused the suggestion to be dropped without trial. For two years the Lamp Testing Bureau maintained a laboratory at 14 Jay Street; but soon outgrew both home and name. The scope of its work continually increasing, it soon became necessary to enlarge its equipment, which heretofore was devoted largely to the testing of incandescent lamps, and provide apparatus for every conceivable electrical test. It then became necessary to have a corporate name more in keeping with the work done by the company and a building large enough to house the apparatus, leave room for expansion and provide comfortable quarters. Accordingly the name of the company was changed to the Electrical Testing Laboratories and large quarters were obtained at 80th Street and East End Avenue, New York City.

The laboratories have but recently been completed and as a description of them has never been published we present herewith a partial account of the equipment, giving only the most prominent divisions of the facilities already at hand. In an effort to offer a satisfactory substitute for a private laboratory, rooms have been provided for the use of those who desire to make their own tests, experiments or demonstrations secretly; the company furnishing the instruments, apparatus and current. Fig. 1 shows the switchboard controlling the motor-generator set which supplies current to the incandescent lamp life-testing racks. This set consists of a 220-h.p. 6600-volt, 25-cycle, three-phase induction motor direct-connected to a 125-volt 60-cycle alternator which is excited from a small motor-generator set the motor of which is operated by 220-volt, 25-cycle, three-phase current. The current generated by the set is at about 117 volts and the average variations in e.m.f. are restricted by means of an automatic regulator supplemented by hand control, to within ¼ volt either way and rarely exceed ½ volt. Curve drawing voltmeters supply records of pressure variations.

From the large dynamo the current is sent into an auto-transformer whence it is distributed to the life-test racks at 41 voltages ranging from 100 volts to 140 volts by steps of one volt. From a smaller auto-transformer voltages ranging from 25 to 300 may be obtained. These are supplemented by small portable auto-transformers. For the testing of series burning lamps a constant current transformer is provided.

Fig. 2 shows one end of the room where incandescent lamps are tested to determine their useful life and candle-hour value. To prevent drop, and consequent variation of pressure with the load, the conductors from the transformers to these racks consist of large copper bars, as shown across the top of the engraving. There are about 6000 receptacles arranged in groups for operation at various potentials. Each receptacle is so arranged that a small resistance can be inserted in its circuit to adjust the pressure to one-tenth of a volt where necessary. Most of the lamps are burned in a horizontal position to develop their tendency toward dropping, if such weakness exists, and every effort is made to determine their faults without submitting them to any unusual strain. A card at each receptacle shows all the data necessary to identify each lamp. At present there are about 2500 lamps burning on the life-test racks.

In adjoining rooms on the same floor are located photometers which are used to determine the candle-hour performance of incandescent lamps under test. Six photometers have been provided for routine work in this connection, and are supplemented by other photometric apparatus designed for the more special work which it is necessary to do in connection with life-tests upon incandescent lamps. All of these photometers have been built specially for use in these laboratories, and are adapted to work of a high degree of accuracy and possess as well great ranges of usefulness. Each is connected separately to a switchboard, to which the various available sources of current supply are also brought, connections being made by means of flexible cable. This makes available for use in con-

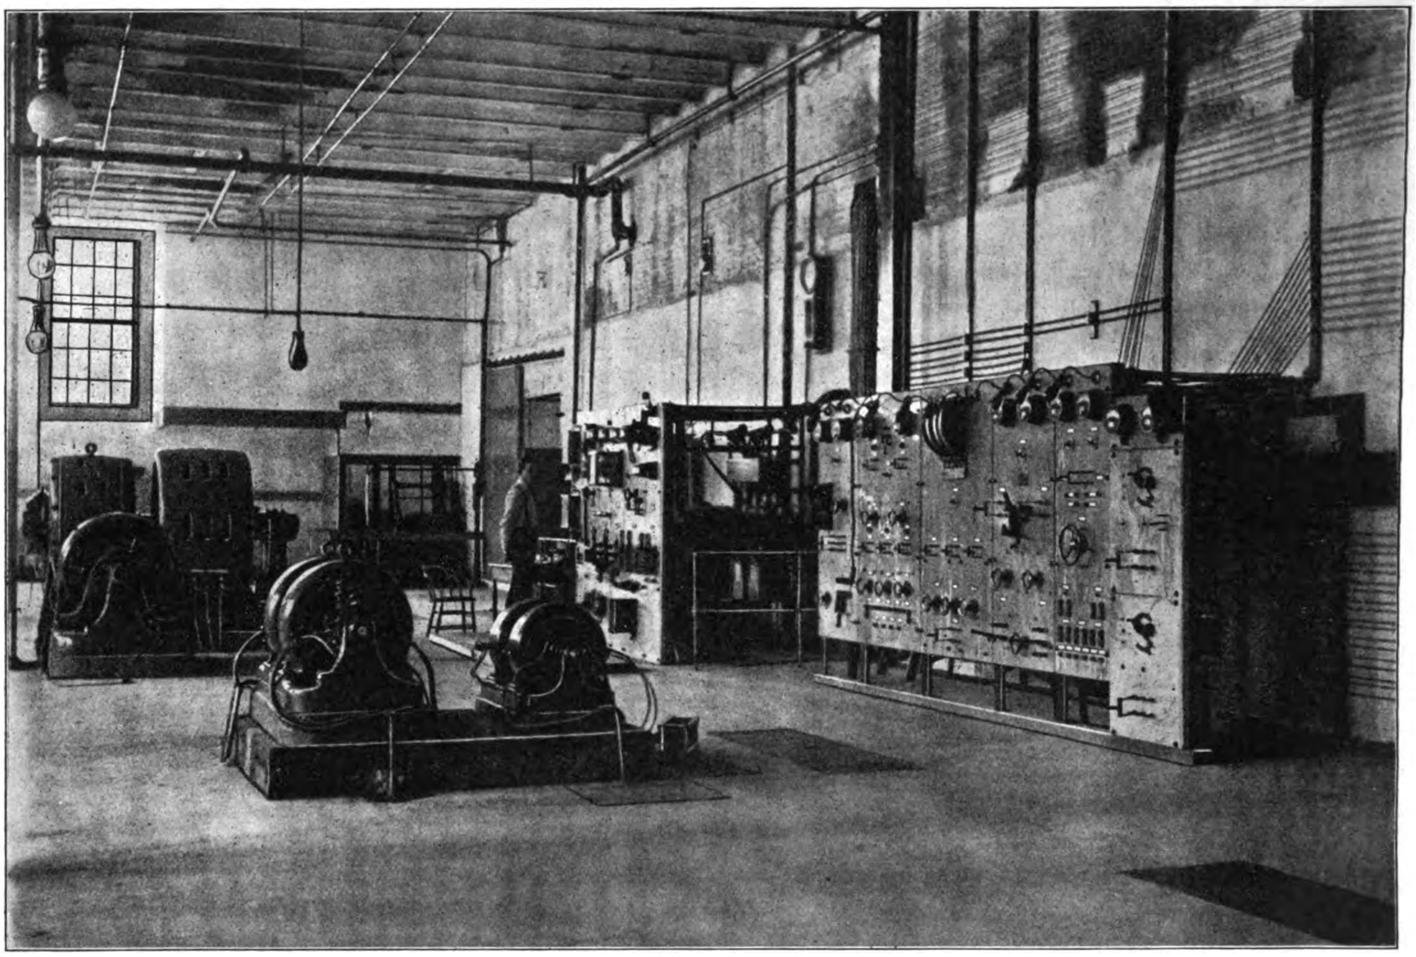


FIG. I.—MOTOR-GENERATORS AND SWITCHBOARDS FOR LAMP TESTING AND STORAGE BATTERY CIRCUITS.

nection with this work nine different storage batteries of various potentials and capacities, as well as the three-wire Edison system and the various sources of alternating current supply. Storage batteries are, with rare exceptions, used for supplying the current for photometric purposes, since where high accuracy is desired, only the steadiest possible pressure is satisfactory. All of these batteries and several others are connected to the switchboard shown in the right of Fig. 1, in the foreground of which may be seen two Crocker-Wheeler motor-generator sets for charging and discharging some of the batteries.

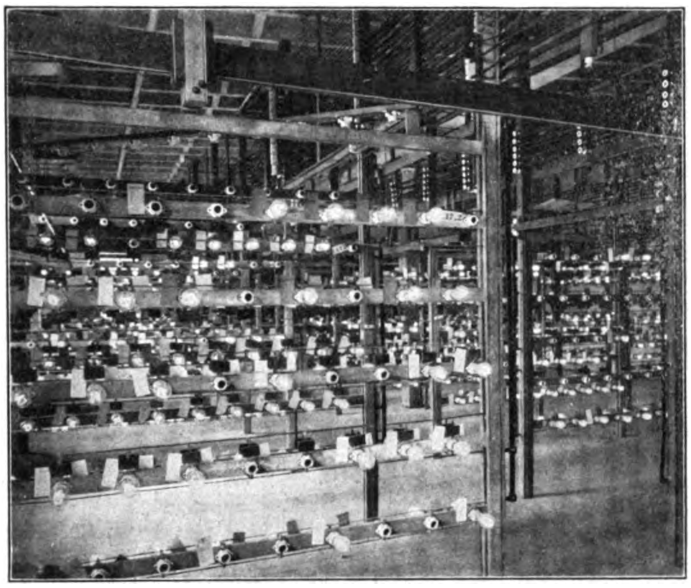

FIG. 2.—INCANDESCENT LAMPS ON LIFE TEST.

Records made in the life-test rooms in the photometric laboratories are taken to the computing room, where they are permanently entered in suitable record books, from which candle-hour values, efficiencies and other data are computed and reports prepared. Arrangements are such that candle-hour tests are conducted by three separate departments, the first two of which are very largely ignorant of the data of these tests since only a few individuals in the computing department know of the results obtained.

The arc lamp photometer equipment is particularly interesting. There is an overhead track from which arc lamps are suspended while burning on life test, one end of which terminates in the photometer. This provides a means for placing the lamp in the photometer with the least loss of time and without interfering with its conditions of burning. The lamp is hung in the centre of a ring of mirrors, 15 degrees apart, so arranged as to focus the light at any point within the scope of the photometer which is about 70 feet long. The photometer bar is mounted on a track and travels the length of the room so that it can be fixed at the best distance for the lamp under investigation: nearer the mirrors for lamps of small candle-power and farther away for larger ones. The general arrangement is after the plan of Prof. C. P. Matthews of Purdue University, who gave much of his time to the design and installation of this apparatus. A recording device is attached to the standard lamp carriage which greatly facilitates the rapidity of making readings. Altogether this arc lamp photometer provides a means for measuring with promptness and accuracy the mean spherical or hemispherical candle-power and distribution of light of arc lamps and the determination of the quality of arc lamp carbons. From the measurements obtained a curve is made showing the distribution of light.

The general photometer equipment is most complete and comprises several types of instruments for many kinds of work, from spectrophotometry to the measurement of the distribution of light by shades and reflectors used with either electric light or gas.

Fig. 3 shows the large rotating mirror device which is used in connection with a photometer for determining the distribution of light about large sources. Its use in confined chiefly to the determination of distribution of luminous intensity about large reflectors or clusters of reflectors, large globes used with either gas or electric lamps, and other large sources of light. In the illustration, a cluster of five incandescent lamps backed by a 13-inch reflector is shown in position, ready for measurement. The device is also used in connection with arc lamp photometry, supplementing the arc lamp photometer described in another paragraph. The apparatus consists of three mirrors, each 22 inches by 31 inches, so mounted that they may be placed at any angle with regard to a certain centre of rotation. The light from the source is reflected from the last mirror in the series to the photometer, always falling perpendicular to the photometer disk. This last feature is of great importance, since with Bunsen or Leeson disks considerable photometric error is introduced if the light falls upon the disk at an angle which varies materially from the perpendicular, which would be the case if a single mirror were rotated about the source of light.

The photometry and life test of Nernst lamps has been provided for by the construction of special apparatus for burning the lamps in a pendant position and taking their candle-power readings without interference with their life test, and with the least loss of time.

There are many types of incandescent lamps on the market designed for special uses. In some the filament is arranged to give the most light in a horizontal plane, in others the aim is to project the light downward; another type claims to afford an equal illumination in every direction. All of these lamps are usually compared in terms of spherical candle-power or total flux of light. Generally such comparisons require considerable labor and skill. The Electrical Testing Laboratories use for such purposes the integrating photometer of Professor C. P. Matthews, which gives with one measurement the mean spherical candle-power of any type of lamp and affords an accurate comparison of the various types on the market. This photometer has been illustrated so often that a description would be superfluous.

To keep all of the photometers in accurate agreement with recognized standards, a standardizing photometer is installed in a separate room with a potentiometer, standard voltmeter, standard ammeter, standard cells and resistance standards; a complete photometric laboratory in itself which can, if necessary, be checked against the standardizing laboratory on the floor above. On this photometer the most accurate work is done, such as the checking of standards against the amyl-acetate and the pentane standards, and the calibration of secondary standards of which the company issues a considerable number. These standard lamps are used by lamp manufacturers, educational institutions and photometrists generally, and are said to be in agreement with the recognized standards authorized by the government laboratories of Europe and America. A spectrophotometer is installed for the purpose of comparing the colors of different lights, such as the carbon arc, the carbon incandescent and the Nernst.

Fig. 4 shows one corner of the general laboratory on the top floor. It contains the instruments of precision by which other apparatus is kept in agreement with recognized standards. In this room are made such tests as the conductivity of wires, insulation of conductors, resistance measurements, checking of standards of e.m.f., current and resistance and work requiring high accuracy. In such work, when the humidity of the air is excessive, trouble is encountered from the moisture which condenses on instruments and their connections, decreasing the insulation and in many instances reducing the accuracy of the tests. To obviate this a refrigeration system is provided, one of the coils of which is enclosed in a box near the ceiling, as shown in the illustration, and so ar-

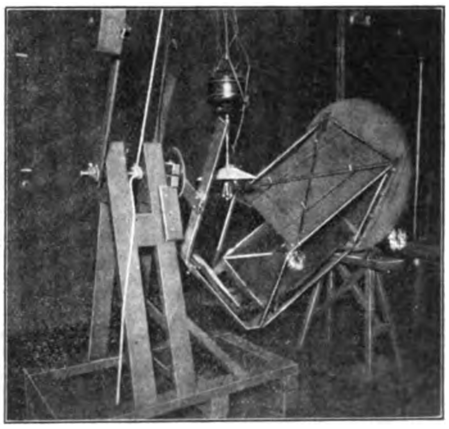

FIG. 3.—ROTATING PHOTOMETER MIRROR.

ranged that the excess moisture can be frozen out of the air. This artificial drying of the air enables accurate work to be done, when otherwise it would be impossible, and is especially important in the calibration of standard voltmeters and ammeters.

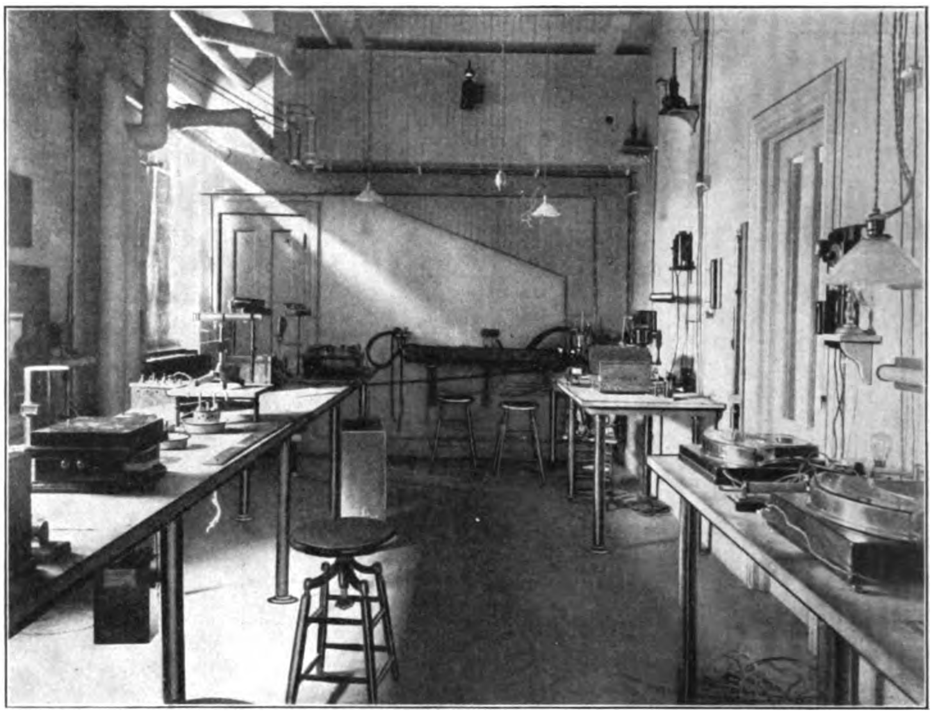

FIG. 4.—CORNER OF GENERAL LABORATORY.

The floor of this room, as well as the general laboratory floor, is covered with linoleum, the tables are of stone on iron legs. One end of the standardizing laboratory is partitioned off to form a constant temperature room, where tests may be made at desired degrees of heat from the lowest limit of the refrigeration apparatus to the limit of high temperature imposed by personal endurance or fire hazard.

In the machinery room on the lowest floor is a special alternating current testing set consisting of two small revolving field alternators driven by motors. The shafts of the dynamos can be coupled so that they can be driven by either of the motors at various speeds to obtain frequencies from 10 to 140 cycles. Leads are brought out for one, two, three, six and twelve phases and by shifting the stationary armatures of the two dynamos and changing their relative positions any phase relation and the power factor can be had at will. This set is of great value in testing integrating wattmeters, checking indicating instruments and in such work as requires alternating current conditions similar to those on the customers' circuits. With this set almost any commercial conditions can be reproduced.

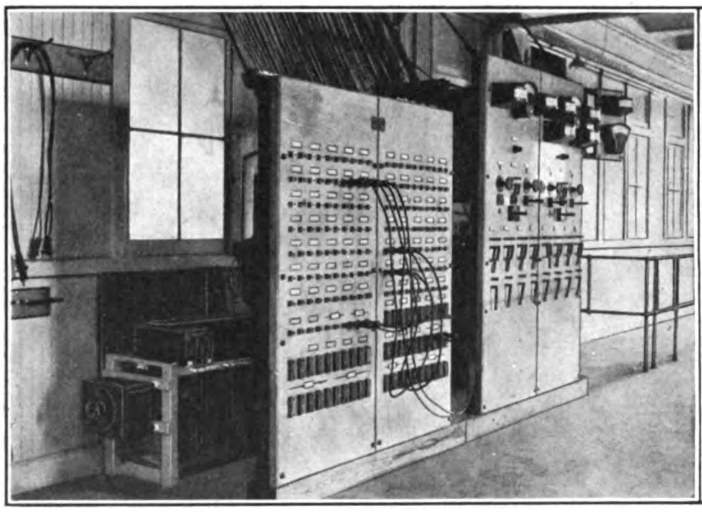

FIG. 5.—SWITCHBOARD FOR DISTRIBUTING ALTERNATING CURRENT TO TESTING CIRCUITS.

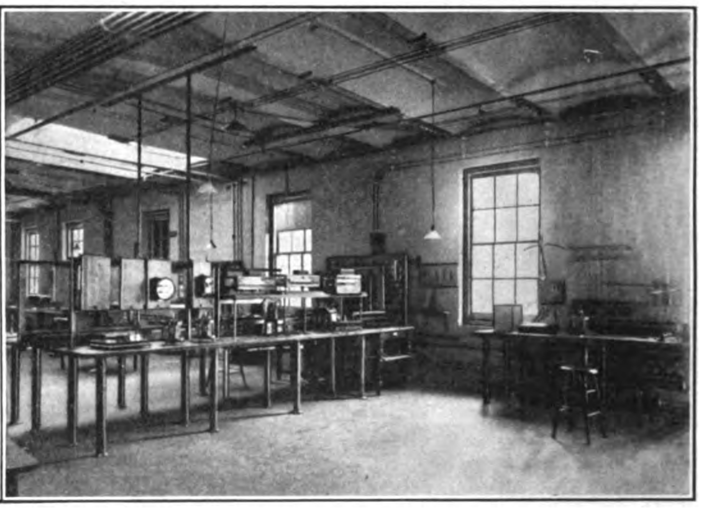

FIG. 6.—HEAVY CURRENT TESTING TABLE.

Fig. 6 shows the table for testing integrating wattmeters and instruments requiring heavy currents. Two stone top tables, built by the Albert & J. M. Anderson Mfg. Co., are provided with heavy bars of copper arranged so that the instruments under test can be cut into circuit in series with certified standards. The table is supplied with current up to 5000 amperes from four large storage cells, which can be arranged in series or multiple, or from a transformer of low voltage and high amperage capacity, and from any other source in the laboratory. Four Kelvin balances are provided as standards of alternating current amperes. The current is controlled by suitable rheostats, some of metal strips, others of carbon plates the whole making what is doubtless the best arrangement for the checking of meters and instruments requiring heavy currents. This outfit is especially useful in making tests of the accuracy of electricity supply meters under various conditions of load, voltage, frequency and power factor.

The same illustration shows a smaller table for the checking of the voltage on the various racks in the life-test room. It is extremely necessary that the average voltage delivered to the lamps on life test be as nearly correct as it is possible to keep it. There is no standard of alternating current voltage; no such means as we have in the potentiometer for determining the value of an alternating current e.m.f. Yet the voltage at the lamps must be kept right. There are several reliable instruments which read both alternating and direct-current volts, and these are used as transfer instruments, being first carefully calibrated on direct current by means of the potentiometer and then used to compare alternating with direct current. Seven methods are employed to standardize the alternating current life test voltage, all of them referring back to the standard cell and potentiometer.

For determining the wave form given by an alternator, the wave-meter is used, which gives a record from which an exact analysis of the wave form can be recorded photographically, or as a curve on cross-section paper. An important instrument which has been provided is an oscillograph. This instrument is used for making a record of rapidly varying currents. It will give a picture of the exact form of an alternating current wave of the fluctuations of a direct current due to commutation, of surging and resonance phenomena in transmission lines and the charge and discharge currents of condensers, of surges produced by opening circuit breakers, etc.

Liberal equipment is provided for making tests of insulators and insulating materials. Transformers of various sizes provide facilities for puncture or breakdown tests as high as 120,000 volts, and a special set of dynamos, operated by a motor, affords direct current at 10,000 volts for such breakdown tests as require a direct current. High tension tests are made on insulators, insulating joints and plugs, strain insulators, tape, cloth, rubber, fibre, condensers, special compounds, slate, marble, stone and many specialties in the insulator and insulation lines. Special ovens are also in use for making life tests of insulating materials at high temperatures to determine the rate at which the samples deteriorate with heat.

In the construction of dynamos, motors and transformers it is desirable that the iron shall be the best procurable for the purpose. It must have high permeability and low hysteresis. The magnetic value of iron can be determined only by systematic testing. Tests of this sort, while very simple in theory, are beset with such pitfalls that they can be safely intrusted only to an expert who has at his disposal the most approved apparatus for the purpose. In view of these facts, the apparatus and methods of the Electrical Testing Laboratories have been selected with special care. Two permeaters have been installed—one the Koepsel permeater, which enables these measurements to be carried to a reasonable degree of accuracy and with great rapidity—and the other the Picou permeameter, which, while not so rapid of manipulation, gives results of the highest accuracy. Test pieces for these permeameters can be in the form of straight bars or little piles of sheets. The necessary apparatus for testing by the ordinary ring method is installed and ready for use.

◆ ◆ ◆

THE SILENT CHAIN FOR DRIVING MACHINERY.

The Morse Chain Company, Trumansburg, N. Y., has made a special study of the application of silent chain driving to severe and limiting conditions which have given trouble with any other method of driving. As a result of thorough and exhaustive investigation, the company has perfected a chain for machinery driving which is said to be adaptable to any class of service whatever. The claims for this chain are that it is not affected by high-speed, very hot or dry atmosphere, or moisture, and will run satisfactorily with but little lubrication. It is stated that in practice the chain does not wear rapidly even when subjected to the most severe extremes of dust, dirt and grit imaginable.

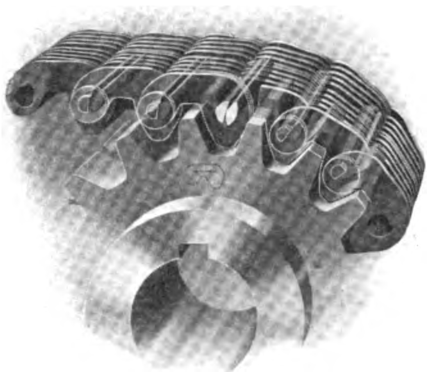

FIG. 1.—MORSE SILENT CHAIN.

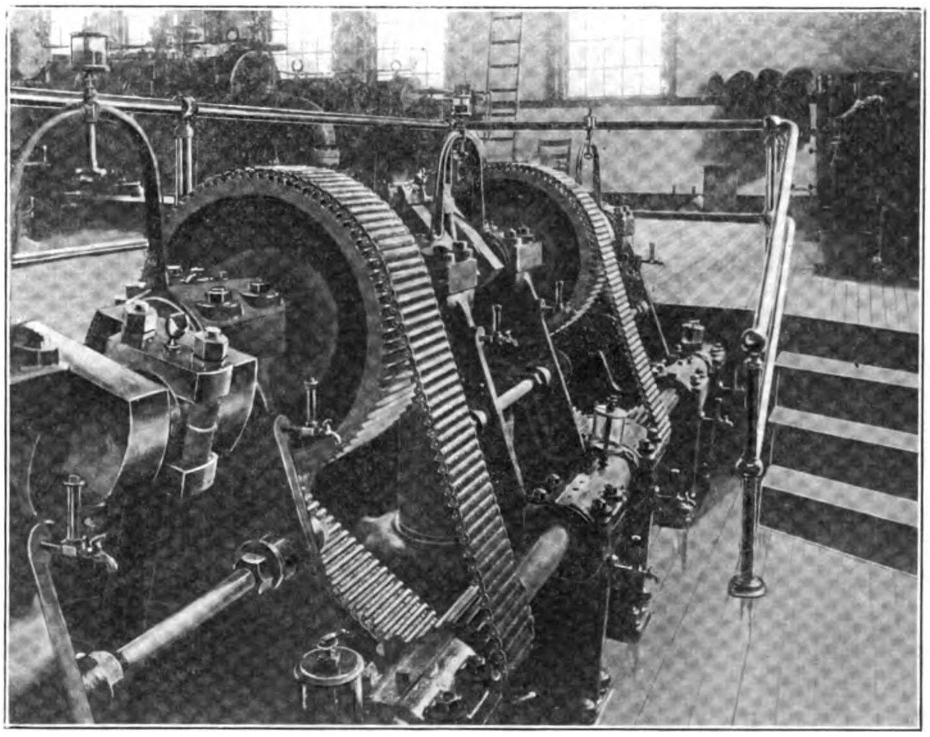

FIG. 2.—CHAIN DRIVE FOR CONDENSER AIR PUMP.

The important feature is that its efficiency in transmission of power is very high, being by actual test from 98½ to 99 per cent.

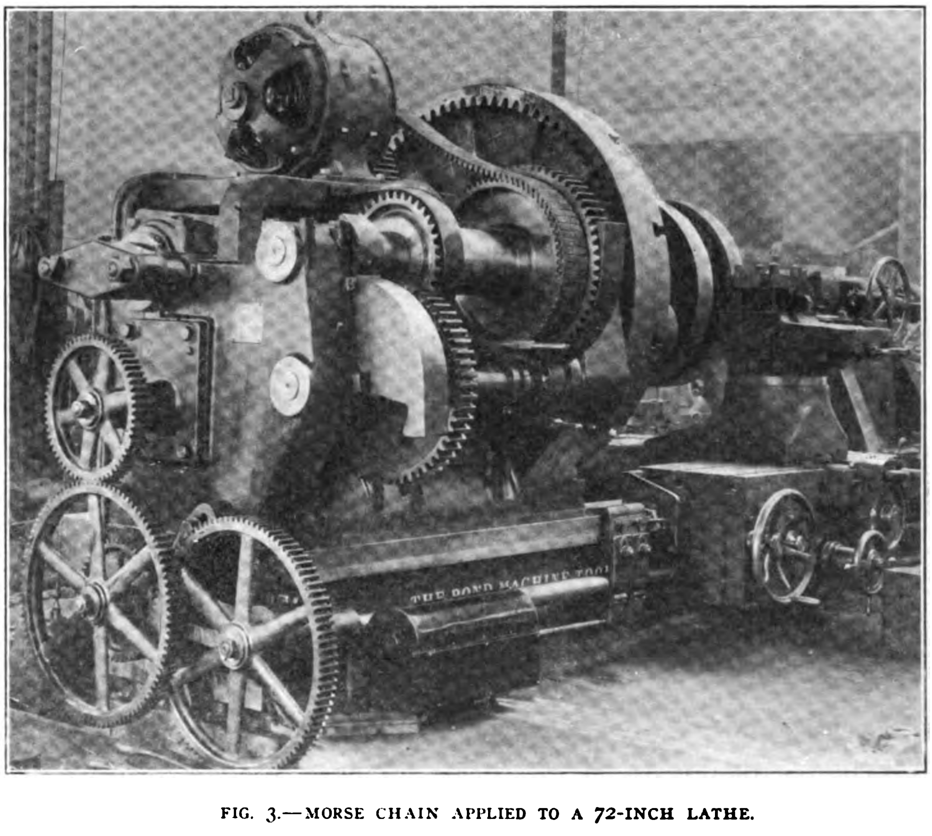

FIG. 3.—MORSE CHAIN APPLIED TO A 72-INCH LATHE.

The construction of the Morse Silent Chain is shown in Fig. 1. The joint consists of two pieces of hardened tool steel, so shaped and arranged that one piece rocks or rolls on the other as the joint passes on and off the sprockets. The two rocking parts of the joint are fixed in opposite ends of the links, and it is claimed that there is only a pure rolling friction on hardened tool steel surfaces with ample contact area to withstand the pressure and that consequently there is no tendency for the joint to wear and cause the chain to lengthen. To prevent undue vibration under high speeds, with the consequent wear, the rocker pins of the high-speed silent running chain are so shaped that the areas of contact surface are greatly increased when the chain is drawn straight between sprockets, in which position a broad bearing is given. The two-part pin used in the Morse rocker joint permits of an unbroken contact the whole width of the chain, less the outside links. As the rocker joint is subjected only to rolling friction it does not require lubrication, and the speed limit is therefore not fixed by the point at which the centrifugal force will throw off the lubricant. A paste grease, sufficiently heavy so that it will not be thrown off at high speeds, affords proper lubrication for the chain in its contact with the sprocket teeth and between the plates of the chain itself. As the pressure between each chain link and sprocket tooth is inversely proportional to the number of teeth in contact with the chain, and as this number is large, the pressure is small.

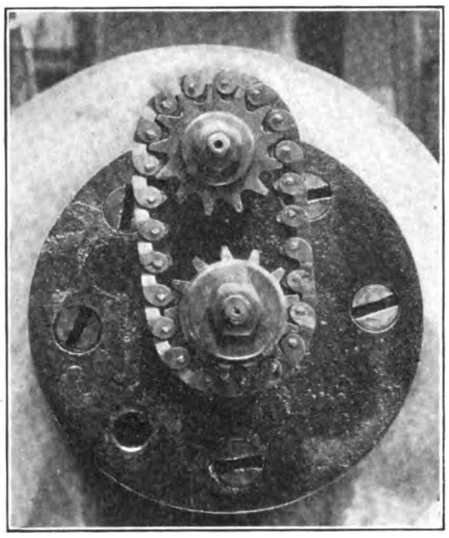

FIG. 4.—CHAIN RUNNING GRINDER ON LARGE BORING BAR.

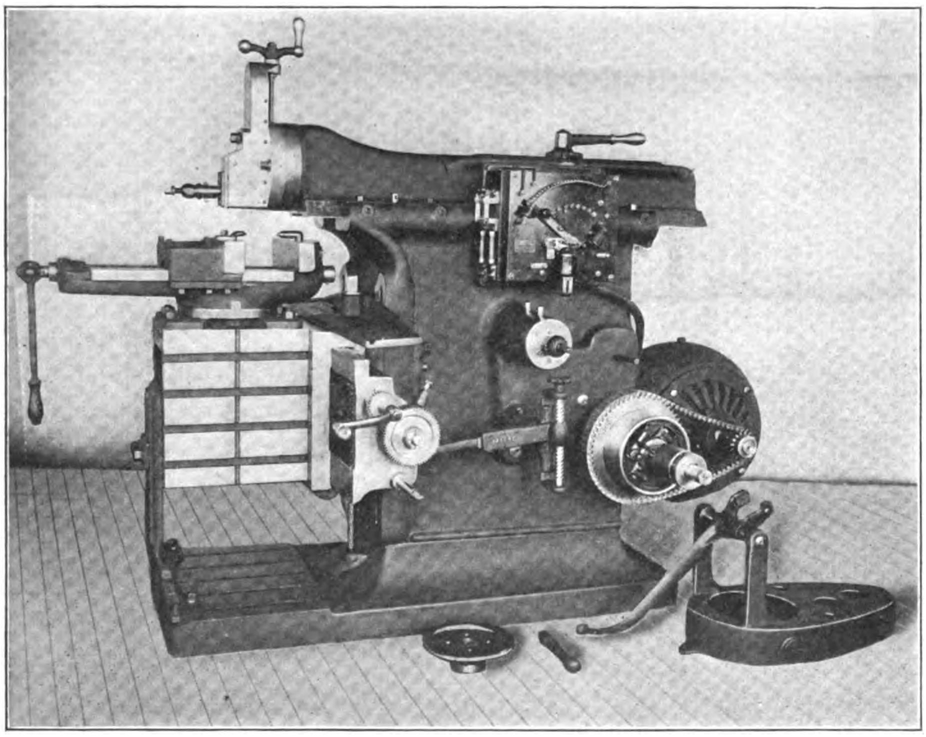

FIG. 5.—MOTOR-DRIVEN EXTENSION-BASE SHAPER.

The sprocket wheels are made of high-grade cast-iron, accurately cut, and in use are found to show little or no wear. For exceptionally hard service or when there is little metal around the shaft, hardened steel sprockets are used. To guide the chain in its passage on the sprockets, special guiding links are used which project below the balance of the chain into grooves turned in the sprockets. The holes in the opposite ends of the links are punched to conform in shape to and securely hold in the large end of the link the rocker pin, and in the small end the seat pin, there being no motion between either part of the joint pin and link. The outside links are bent laterally so that the large end comes under the small end of the adjoining link to permit of the proper engagement with both seat and rocker pin. The joint pins are made of the best grade of tool steel carefully hardened, the shouldered ends of the seat pins being softened to permit of being riveted in the outside links, or in washers in the larger pitches, to hold the chain together.

The accompanying illustration (Fig. 2) of two chain drives from a motor-driven shaft to two condensing pumps illustrates the use of the Morse silent chain under conditions where belts could not possibly be used. These chains were introduced here to replace gears formerly used, on account of the noise of the latter. The maximum pull on the chain is 10,000 lbs. which alternates to 300 lbs. negative pull at each stroke, due to the intermittent action of the pumps, but over two years' service shows no depreciation. Fig. 3 shows the application of a chain drive from a 15-h.p. variable-speed motor to a 72-in. lathe. The compactness and convenience of this arrangement is an interesting feature. Fig. 4 illustrates the use of the Morse chain for driving a grinder on a large boring bar. The chain speed in this case ranges as high as 1150 feet per minute. It operates noiselessly, and its compactness is readily discernible. Fig. 5 shows the application of a Morse chain to a motor-driven shaper.

A NEW MOTOR SPEED CONTROLLER.

For controlling the speed of a constant-potential motor, the advantages of variable applied e.m.f. over rheostatic control are too well recognized to require enumeration here. In alternating-current work, variable voltage is easily obtained by means of transformers, but in direct-current practice it has been necessary either to employ a motor-generator to supply each motor with variable voltage or to install a multi-voltage generating and distribution system. The American Electric & Controller Company, New York, has developed a controller which is designed to meet the requirements of variable-speed work by means of variable voltage without resorting to either of the expedients mentioned. Fig. 1 gives a view of the latest form of this controller and Fig. 2 is a diagram of connections for it. The underlying principle of the apparatus is the variation of effective power in an electric circuit by supplying the power intermittently, varying the proportion of the total time during which the motor actually receives power from the supply circuit.

In series with the armature of the controlled motor is connected a combination of contact bars resembling an ordinary dynamo or motor commutator; this is the "interrupter," and it is rotated at a constant speed of 1500 r.p.m. by a small motor mounted directly on the lower end of the shaft on which the interrupter is mounted. Two groups of ordinary carbon brushes, fed in reaction brush-holders, are in con-

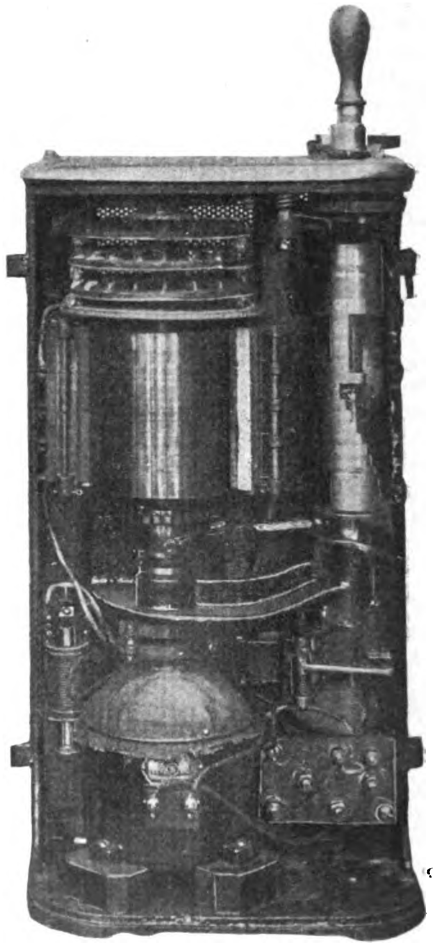

FIG. 1.—MOTOR SPEED CONTROLLER.

tact with the interrupter at diametrically opposite points; these are the terminals of the interrupter. The bars of the latter are arranged so that more or less of them can be put into the circuit, thereby varying the length of time the circuit is interrupted during each revolution of the interrupter; the fewer the number of segments connected in, the shorter the length of time the circuit is closed during each revolution and, consequently, the less energy is received by the motor, since energy is the product of power × time. A peculiar feature of the apparatus, however, is that the rapid interruptions of the circuit not only reduce the energy delivered to the motor by reducing the time of application per revolution, but they also reduce the voltage at the brushes of the motor, thereby reducing the power as well as the energy. The torque of the motor is not reduced at all, so long as the load is such as to keep the current at the same value, for the reason that the torque is directly proportional to armature current × field strength, and the latter is constant within the working range of the interrupter.

The interrupter itself gives a speed range of two to one; for further range, field control is employed. The controller handle operates a small contact cylinder which controls the various circuits with the following results: First, the motor driving the interrupter is put in circuit; next the working motor is connected to the supply circuit with the field winding directly across the circuit and the armature in series with the interrupter, of which the smallest number of segments is now active; this starts the work motor at its lowest speed, the impressed voltage being minimum. The next move of the controller handle increases the number of interrupter segments in circuit, thereby increasing the impressed voltage and increasing the speed of the work motor; further movement increases still further the number of active interrupter segments, until all are finally in circuit except a few which always remain dead in order to interrupt the circuit during each revolution. The next movement of the handle short-circuits the interrupter and leaves the work motor running as a plain shunt machine at full voltage; the little motor driving the interrupter is left in circuit at this point to keep the interrupter revolving "dead" under the brushes and allow it to be polished. The next move cuts out the interrupter motor and inserts resistance in the field circuit of the work motor; successive movements insert more and more resistance in the field circuit, giving the additional speeds by field control in the ordinary manner. The speed gradations are almost imperceptible within the range of the controller, there being no "jumps" or abrupt changes whatever.

The controller is equipped with both undervoltage and overload safeties; the small magnet on the right of the diagram releases a spring-opened switch in the main circuit when the voltage drops or fails and the magnet on the left "kills" the one on the right when the current becomes excessive.

Sparking at the brushes of the interrupter, as the main circuit is opened by the "live" segments leaving the brushes, is reduced to a negligible point by the use of inductance or "choke" coils connected to the segments; these coils are mounted in between the discs shown at the upper end of the interrupting commutator.

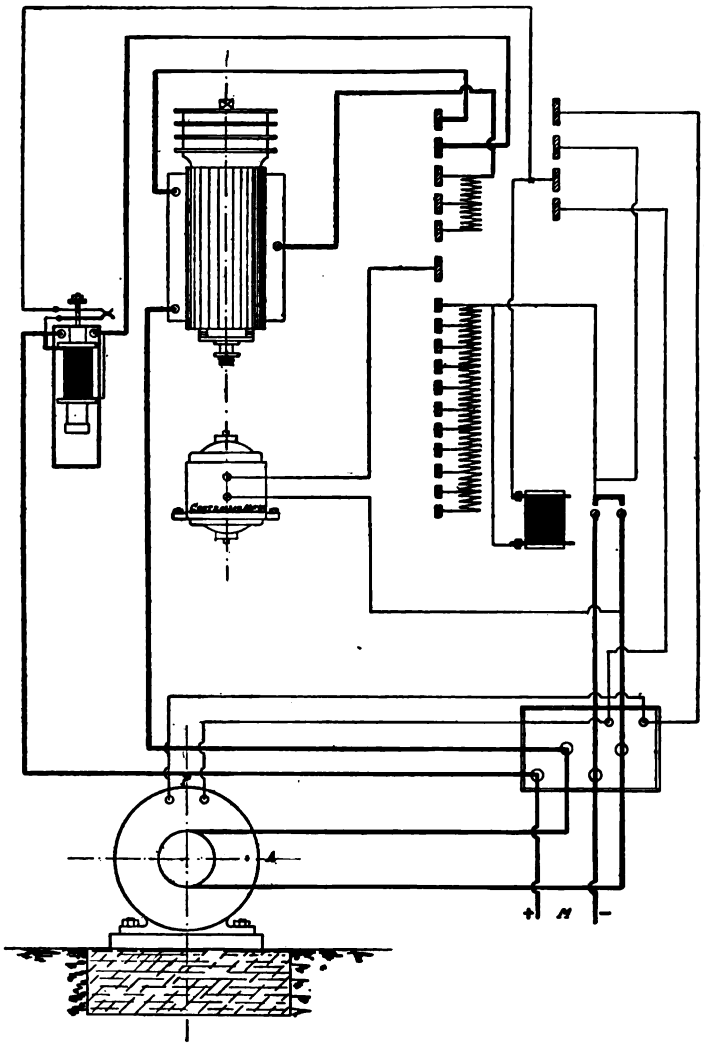

FIG. 2.—DIAGRAM OF CONTROLLER CONNECTIONS.

The controller is fitted with a reversing switch similar to that used on street railway motor controllers and interlocked with the main controller spindle in the same manner, so that the controller handle cannot be turned from the "off" position when the reversing switch is not in proper position for either forward or backward running, and the reverse switch cannot be thrown while the controller handle is at any other point than the "off" or standstill position.

AUTOMATIC BLUE PRINTING APPARATUS.

Fig. 1 illustrates a very compact outfit for making large blue-prints which has been perfected and marketed by the Pittsburg Blue Print Company, Pittsburg, Pa. The apparatus here shown comprises a cylindrical glass holder, divided into two semi-circular parts and provided with spring clips which hold the drawing, blue-print sheets and canvas backings in place on the glass sheets. The cylindrical frame is mounted on a cast-iron base provided with rollers so that the frame may be revolved about its vertical axis for "loading." The light for printing is supplied by an arc lamp suspended from chains which pass over guiding rollers to a set of sheaves on the vertical baseboard mounted on the pillar shown at the left of the printing cylinder. A small electric motor on the vertical baseboard draws one pair of the operating sheaves up or lowers them, according to the requirements; when the sheaves are drawn upward, the lamp chain is hauled in and the lamp raised, and vice versa. The chief object in using the operating sheaves is to obtain a reduction in travel; the traveling sheaves move only about one-third the distance through which the arc lamp travels. The motion is reversed automatically by means of a nut on the screw which draws the traveling sheave up and down, this nut operating a reversing switch at the top and bottom limits of its travel. The whole operating mechanism is based on exactly the same principle as the Sprague-Pratt elevator hoisting machine.

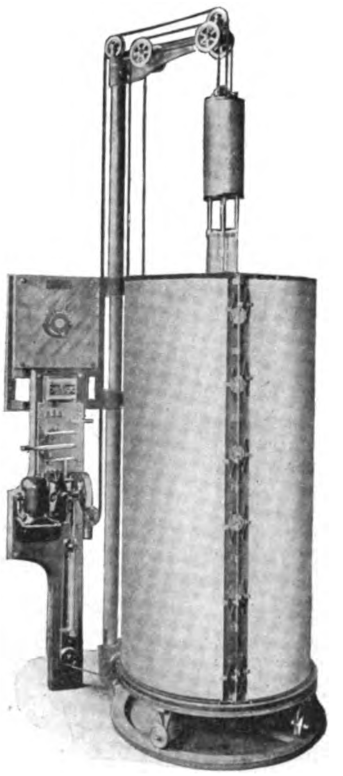

FIG. 1.—BLUE-PRINTING APPARATUS.

New Apparatus and Appliances

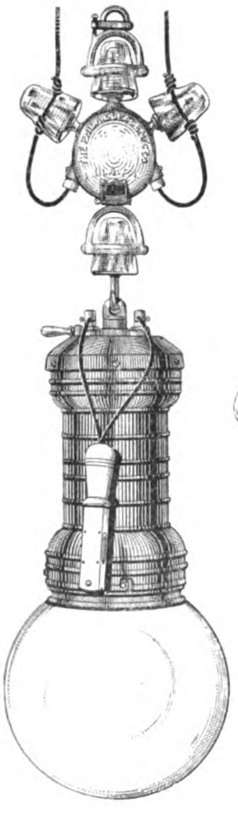
PATENT TAP AND REAMER WRENCH.

Fig. 1 herewith shows the Nichols patent tap and reamer wrench manufactured by the J. M. Carpenter Tap & Die Company, of Pawtucket, R. I. The wrench is made of drop forged steel and has hardened tool steel jaws. No pin, wire or other complement is needed to tighten its jaws on the tap or reamer, the hand alone being sufficient. Its construction is clearly shown in the illustration. The handle does not rotate so that the grip on the tap or reamer is not loosened when once fastened. The wrench is made in five sizes, the whole lengths varying from 7 to 30 ins.

FIG. 1.—NICHOLS PATENT TAP AND REAMER WRENCH.

IMPROVED CUT-OUT.

Fig. 2 herewith shows the "absolute" cut-out made by the Philadelphia Electrical & Manufacturing Company, Philadelphia, Pa. The cut-out is designed for use on either direct or alternating current and is unique in that the lamp can be entirely disconnected from the line. The enclosing case of the switch is made of galvanized cast-iron and the other metal portions of the switch such as the hook, hanger, etc., are made of brass. The handle or plug to which the lamp is attached is made of porcelain, so that the insulating qualities of the switch are not lacking. Reference to Fig. 3 will show how by simply pulling the handle out of the switch the lamp is disconnected from the line, and also the impossibility of cutting out the lamp without first closing the line, and vice versa the impossibility of opening the line without cutting the lamp in. The switches are made in two styles as shown in the illustrations, Fig. 4 being intended for attaching permanently to the pole or cross-arm, and for testing purposes also.



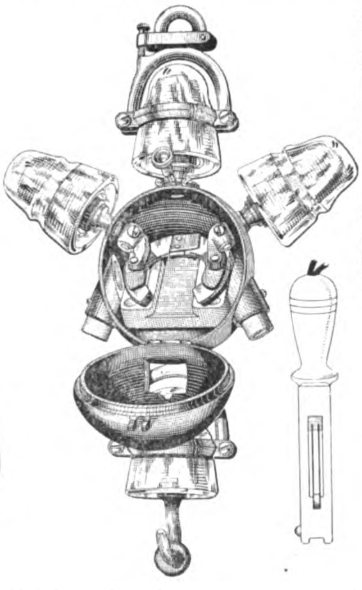


FIG. 2.—IMPROVED CUT-OUT—FIG. 3.

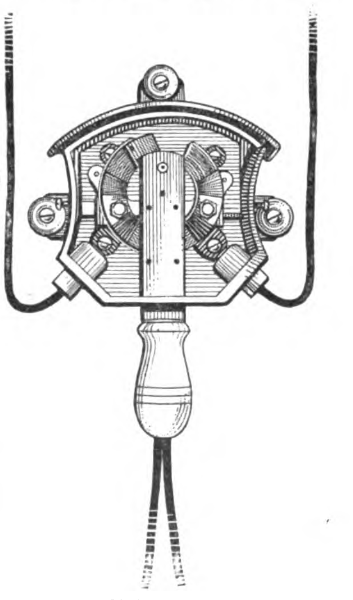

FIG. 4.—STATIONARY TYPE OF CUT-OUT.

BIPOLAR ENCLOSED DIRECT-CURRENT MOTORS.

The Emerson Electric Manufacturing Company, of St. Louis, Mo., has brought out a line of enclosed bipolar motors for direct current ranging in size from 1-20 to 1/6 horse-power. These machines are spherical in form and have a removable shutter giving access to the commutator and brushes. The field rings and poles of these motors are cast solid, and the field coils are form wound, taped, dipped and baked. The armature is made up of laminations of soft steel, pressed on the shaft and secured by collars pinned to the shaft which is of tool steel. The commutator is well made and the leads from the armature coils are protected by a wrapping of fine cord. Square carbon brushes are used with cartridge type holders of special design. The field leads on both the shunt and series motors are brought out through an insulating bushing in the frame, and all connections to brush holders are made outside the motor. These types may be readily reversed without removing the shutter. The motors are self-contained, no starting box being required. They are wound in two frames of similar design, but differing slightly in dimensions. Motors in either frame can be wound, shunt or series, for three speeds. Shunt windings in the smaller frame develop from 1-20 to 1-12 horse-power, at speeds from 1800 to 3000 r.p.m.; in the larger frame from 1-10 to 1-6 horse-power at speeds from 1500 to 2000 r.p.m. The highest speed windings, however, are not recommended for continuous service under full rated load.

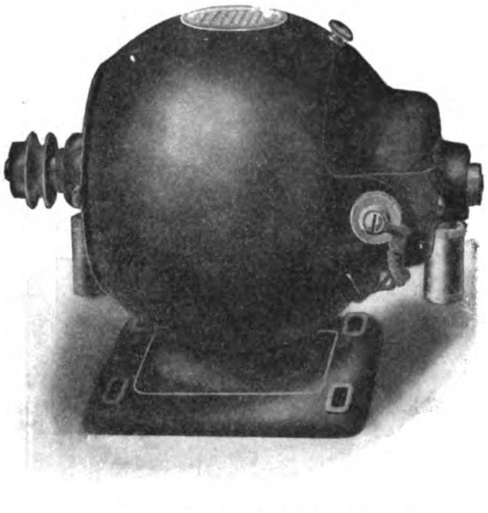

FIG. 5.—EMERSON ENCLOSED MOTOR.

COMBINATION SWITCH AND PLUG CUT-OUT.

A new line of combination switch and plug cut-outs has just been placed on the market by H. T. Paiste Co., Philadelphia, Pa., called "P-K" panel cut-outs. These comprise 25 and 30-amp. mains for 125 and 250-volt circuits, and single and double branches for both two and three-wire systems. In addition to the six styles of cut-outs in this line, the company furnishes oak panel-box fronts complete with rim locks and key, or the wooden panel-boxes entirely separate from the fronts. These boxes are lined with 1/8-in. asbestos board, and are all ready for setting into the studding. With this line of material at his service, the wireman can build his own panel boards of any number of circuits. The material is said to be approved by the National Board of Fire Underwriters.

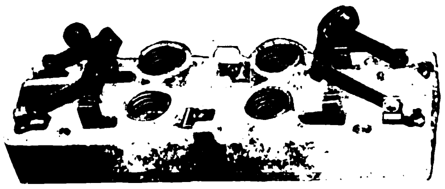

FIG. 6.—SWITCH AND CUT-OUT.

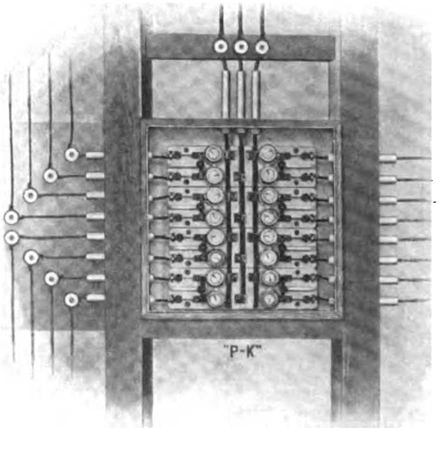

FIG. 7.—PANEL BOARD.

TRANSFORMER FOR THAWING OUT FROZEN WATER PIPES.

Although the application of electricity for thawing out frozen water pipes is not a new idea, it is only within the past few years that it has generally been adopted by central stations. During the severe weather of last winter this method seems to have received an astonishing impetus. Station managers who started out in a small way to thaw pipes to accommodate customers, in a short while found themselves overwhelmed with requests for relief from plumbers' bills and expensive excavations. The General Electric Company, in response to a general demand and realizing the superiority of electrical thawing over the old, inefficient and expensive method of opening the frozen ground and applying fire externally, has developed a transformer outfit for this special purpose, which can be easily connected to alternating current circuits in the vicinity of frozen pipes. The outfit has been designed to stand rough handling and outdoor service, and adjustments over wide ranges of both secondary voltage and current are readily made. The transformer is designed to operate on circuits varying from 2000 to 2300 volts, 60 cycles, and its secondary voltage and current may be readily adjusted from 0 to 75 volts and 0 to 400 amperes by means of an adjustable core or flux shunt controlled by a hand wheel and locking device. The transformer core has three horizontal legs with a closed magnetic circuit at the ends. Flat pancake coils are threaded on the middle legs and spaced apart so as to permit an adjustable flux shunt to move up and down between the primary and secondary coils. This device constitutes a bridge arranged to shunt a varying amount of the primary flux out of its normal path through the secondary coil. When the shunt is in the lowest position it diverts the primary flux from the secondary coil, and when it is in its highest position permits practically all the flux to thread the secondary coil; while at intermediate positions corresponding amounts of the flux thread the secondary coil. This construction affords a simple and convenient method of obtaining any voltage and current from zero to maximum capacity. Fig. 8 shows its construction and the simple method of controlling the flux shunt. The leads of the primary coil are brought out to a suitable connection board, on the side of the transformer, on which are mounted primary switches, fuses and an ammeter. The terminals of the secondary coil are brought out to heavy lugs, at the end of the transformer, from which heavy cables can be run to the proper pipes to be thawed. The outfit complete, including transformer, switches, cover and meter, weighs approximately 1200 lbs. It is mounted on four broad flanged wheels to permit its being quickly loaded on a wagon bed or sleigh. The space occupied by the transformer is approximately 20 ins. x 30 ins., with a height of 36 ins. The coils are insulated in a manner similar to the well known General Electric constant current transformer coils. The conductors are individually well insulated, the insulation between layers is strong and the coil as a unit is subjected to a vacuum drying and compound filling process which effectively prevents the absorption of moisture when the apparatus is used in damp places. After filling the coils are taped and varnished repeatedly until the insulation is more than sufficient to withstand the pressures to which it will be subjected in actual operation. While the rating of the secondary coil is 75 volts and 400 amperes, for temporary operation, especially under the normal conditions of its use in winter time, a very much larger current may be taken from the transformer. For instance, starting with the transformer cold on a winter's day it will be perfectly safe to take 800 amperes for ten or fifteen minutes, and smaller currents can be taken out for correspondingly longer periods. While the transformer is rated at 2200 volts primary, it can be safely operated at voltages up to 2500 and down to 1500. It must be borne in mind, however, that as the primary voltage is reduced below its normal value, the voltage which can be obtained from the secondary will also be reduced.

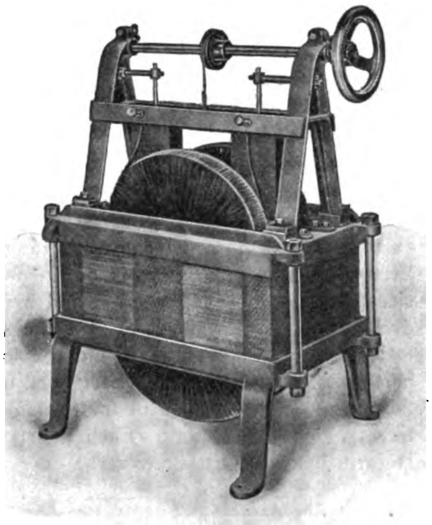

FIG. 8.—TRANSFORMER FOR THAWING OUT PIPES.

HORNSBY-AKROYD OIL ENGINE FOR WIRELESS TELEGRAPH SERVICE.

Fig. 9 herewith shows a 50-h.p. Hornsby-Akroyd safety oil engine, which size and type of engine is to be used by the Navy Department for driving electric generators at the long distance wireless telegraph stations to be operated by the department in Panama and Cuba. A number of smaller units of this type have been operated by the government in the fortifications, lighthouses and wireless telegraph stations on the Atlantic coast. The installations at Key West, San Juan, Guantanamo and Colon have already been completed. The engine consists, as shown, of two standard engines rigidly bolted to a common bed plate. The crank-shaft is in one piece, the cranks being placed alike on the shaft so that both pass the dead center at the same moment. The operation of the engine has been frequently described in these columns so that it is unnecessary to refer to it at length again. It may, however, be mentioned that the engine operates on the four-stroke cycle which consequently gives an impulse in each cylinder at every other revolution, so that in the engine illustrated an impulse will be received every revolution. The fuel used is ordinary kerosene oil, fuel or crude oil. The oil tank is placed under the base of the engine and the fuel is pumped automatically to the vaporizers. The engine is started by means of compressed air and does not at any time require the services of more than one man. When in operation the engine only requires the occasional filling of the lubricators, and the daily replenishing of the oil in the tanks. In the acceptance tests, these engines were said to have shown a fuel consumption of ¾ lb. per actual horse-power per hour. They also carried a 25 per cent overload and the variation in speed with even load was less than 2½ per cent and less than 3 per cent when the load was changed from full to ¼ load. The engines are built by the De La Vergne Machine Company in sizes up to 125 horse-power in single cylinder units.

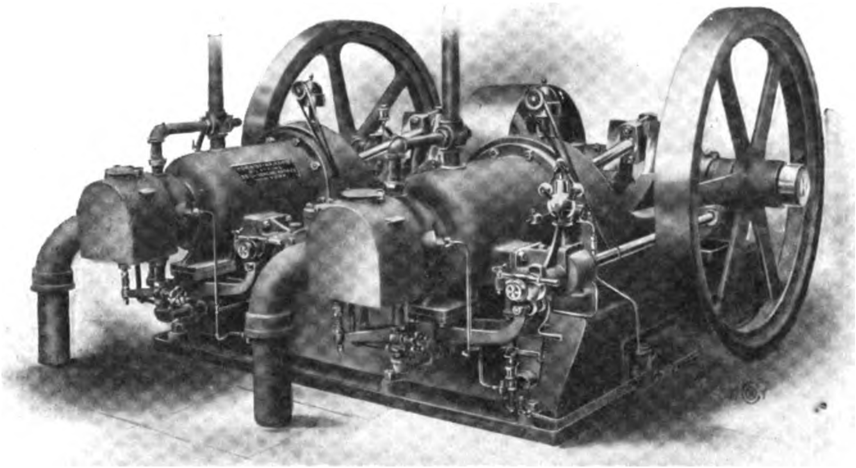

FIG. 9.—HORNSBY-AKROYD OIL ENGINE.

TRANSFORMER FOR PIPE THAWING PURPOSES.

The Pittsburg Transformer Company, Pittsburg, Pa., has brought out the transformer intended for pipe thawing purposes shown by Fig. 10 herewith. The outfit consists of a transformer adapted to operate on any circuit of approximately 1100 or 2200 volts and 60 or 133 cycles. The transformer will deliver a current of 300 amperes continuously or currents up to 600 amperes for periods of half an hour. Mounted on the back of the transformer are a heat indicator and a choke coil. The indicator consists of a section of lead pipe connected in series with the transformer, the temperature which this assumes being a guide as to the heating of the pipe under treatment. The choke coil consists of a few turns of heavy copper bar, with a movable laminated core. When the plunger is pushed entirely into the coil, the secondary of the transformer may be short circuited, but no more than normal current will flow. In operation, the transformer is connected to the primary line in the usual way, the connections on the porcelain terminal block being altered, if necessary, to adapt it to the line voltage. When all the other connections are properly made the plunger is pulled out gradually until the indicator is hot enough. Suitable connectors are provided for attaching the cables leading from the water pipes, and the transformer connections are tagged to avoid error. No. 0 wire or cable is recommended for secondary connections. It is necessary when operating the outfit to protect the transformer with a fuse and to provide a 400-ampere single or double-pole switch. The company has also printed in connection with the outfit circulars for mailing to prospective customers and placards to hang in public places. These are furnished at cost.

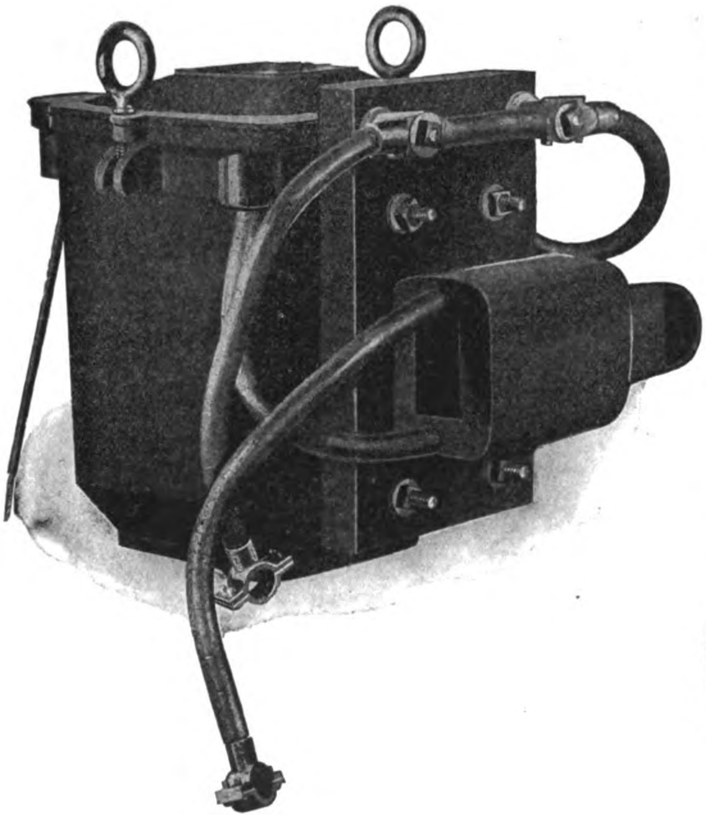

FIG. 10.—TRANSFORMER FOR THAWING PURPOSES.

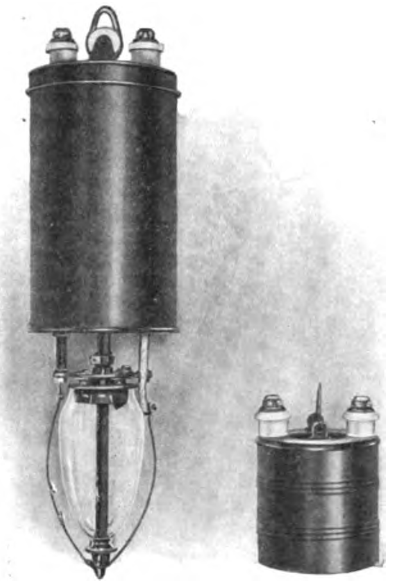
PHOTO-ENGRAVING AND BLUE-PRINTING ARC LAMP.

Fig. 11 herewith shows an enclosed photo-engraving and blue-printing arc lamp made by the Adams-Bagnall Electric Company, of Cleveland, Ohio. This lamp in construction is very similar to the other types of lamps made by the company and embodies all the well-known features of the A-B lamp. Fig. 12 shows the diagram of connections. The lamps are made for either direct or alternating current and for 110 or 220-volt circuits. The manufacturer recommends the 220-volt, direct-current lamp where conditions are such that it may be used. The violet rays which are most desirable for photoengraving or blue-printing purposes are obtained by operating at this voltage. In order to facilitate the handling of the lamp the external resistance in the direct-current and the reactive-coil in the alternating-current lamps are enclosed in an external case as shown. Both types of lamp are of the solenoid type. Other features are shown in the engravings.



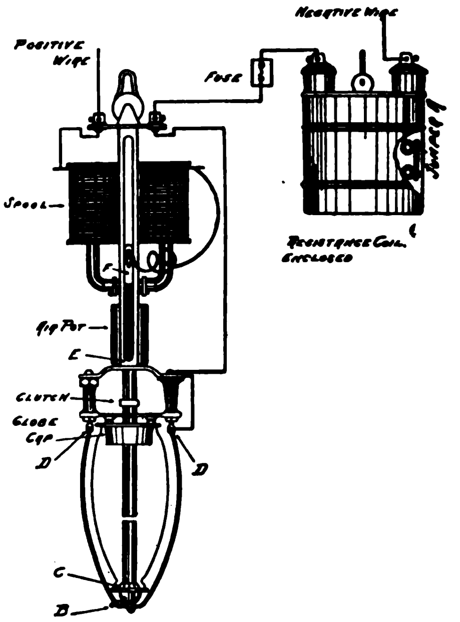


FIG. 11.—BLUE-PRINTING ARC LAMP AND CONNECTIONS.—FIG. 12.

ROBERT COMBINATION VOLT-AMMETER.

The Detroit Electric Company, of Detroit, Mich., has brought out the combined voltmeter and ammeter shown by Fig. 13 herewith. The instrument is of the watch size type with a clearly drawn and equally divided scale. The upper part of the scale is used to indicate amperes and the lower part volts. The instrument is claimed to be dead beat and is convenient for testing batteries and small motors. Each instrument is furnished in a leather case.

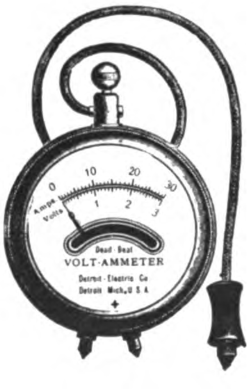

FIG. 13.

NEW BOOKS.

Handbook on Engineering. By Henry C. Tulley. (Fourth Edition.) St. Louis, Mo.: H. C. Tulley & Co. Soft leather; 966 pages, 4¾ ins. x 6½ ins.; 402 illustrations. Price, $3.50.

This edition of Mr. Tulley's book shows evidence of revision, particularly in the refrigeration section and the addition of a chapter of tables. A few of the errors that were in former editions still remain, however. On page 727, for example, the diagram of connections shows the shunt field winding of a reversing motor connected permanently to the brushes, so that the current is reversed in both field winding and armature when the reversing switch is thrown over; it is needless to say that the direction of rotation cannot be reversed with such connections. In the new chapter of tables the reviewer notes several that have been reproduced by photo-engraving from another hand-book without acknowledgment, which is not strictly in accord with the ethics usually observed. In the table of "Properties of Saturated Steam," the total heat above Fahrenheit zero is given instead of the total heat above 32°, rendering this column useless. The tables of boiler and engine dimensions should be very useful; there is also an excellent table of pump dimensions and capacities. A most welcome, though not vitally important, improvement in this edition is the numbering of the illustrations consecutively throughout the entire book. The book has been improved in a number of other minor points also, and after a few more revisions should be substantially above criticism. If the foregoing comments seem at all harsh (which is not intended to be the case), it should be remembered that from ten to fifteen revisions are usually required to make a book of this class free from errors and inaccuracies.

Logarithms for Beginners. By Charles N. Pickworth. New York: D. Van Nostrand Company. Buckram-covered boards; 52 pages, 5 ins. x 7⅛ ins.; 3 tables. Price, 50 cents.

This is an excellent little exposition of the practical application of logarithms. The author starts at the beginning and explains the elementary mathematics on which logarithms are based before taking up the subject proper. Then logarithms and their uses are explained in the simplest of language. Numerous examples are given, together with their answers; for convenience in working the examples, a table of four-place common logarithms and one of four-place anti-logarithms are given. There is also a table of the logarithms of useful numbers, the latter including π and its reciprocal and many sub-multiples. We accordingly recommend the book to anyone who is at all "foggy" on the subject of logarithms.

Mechanical Engineer's Reference Book. (Second Edition.) By H. H. Suplee. Philadelphia: J. B. Lippincott Company. Soft leather; 867 pages, 4 ins. x 6¾ ins.; numerous illustrations and tables. Price, $5; with thumb index, $5.50.

This edition of Mr. Suplee's reference book has been revised to the extent of correcting all the known errors in the first edition and adding twenty pages to the appendix. These additional pages contain tables of Navy standard dimensions of welded flanges for steel pipe, strengths of alloys, composition and uses of alloys, data on flattened strand hoisting rope, shearing strength of rivets, influence of heat on the strength of steel, flow of air through pipes and orifices, classification of locomotives, strength and weight of fly-wheels, friction of water in pipes, and the Crocker-Wheeler system of multi-voltage motor drive. The mechanical work on the book is fully up to the high standard of that which characterized the first edition, and the work has our cordial commendation.

WORLD'S FAIR AWARDS.

It is to be regretted that no official list of the awards by the juries appointed for the purpose of judging the exhibits has yet been issued by the officials of the St. Louis Exposition. We have, however, secured some information from the exhibitors themselves as to the awards received by them, and on this the following list is based.

The awards to the Allis-Chalmers, General Electric and Westinghouse Companies were mentioned on page 607 last month, and therefore will be omitted here.

Electrical Machinery and Apparatus.—Wagner Electric Manufacturing Company received gold medals on its single-phase motors and transformers; also a silver medal on indicating instruments. The jury of awards made thorough tests of the Wagner apparatus, so that the awards were not made on inspection or factory records.

The Electric Controller & Supply Company was awarded a gold medal for its exhibit, which consisted of motor controllers of several types, magnetic friction and stop brakes, cushion-type solenoids, lifting magnets, resistance banks and a working exhibit of variable-speed motor drive for planers.

The Jandus Electric Company exhibited arc lamps and desk and ceiling fan motors, both of which took the highest awards in their respective classes, namely, a gold medal for the arc lamps and a bronze medal for the fan motors.

The Adams-Bagnall Electric Company was awarded a gold medal on its exhibit of A-B enclosed-arc lamps.

Cooper Hewitt Electric Company has been awarded the Grand Prize for the development of the mercury-vapor arc lamp and also received a gold medal for vapor lamps for photo-engraving work.

Batteries and Auxiliaries.—The Electric Storage Battery Company received three awards; a gold medal for storage batteries, controlling and regulating apparatus (booster system); a gold medal for its exhibit of a model central station storage battery outfit, with booster regulation, and a silver medal for switchboards for controlling and regulating storage batteries.

Battery Supplies Company was awarded the bronze medal for its exhibit of primary batteries; this, we understand, was the highest award in this class.

Smaller Electrical Appliances.—Holophane Glass Company received three gold medals and two silver medals for its exhibit of glassware for electric lighting.

The Locke Insulator Manufacturing Company was awarded a gold medal for its well-known glass and porcelain insulators for high potentials and special insulating material.

The D. & W. Fuse Company captured a silver medal (the highest for its class of exhibit) for its well-known product.

Hugo Reisinger feels a pardonable pride in his award of a Grand Prize for "Electra" Nurnberg carbons for arc lamps.

Bogia Regulating Socket Company has been advised that its exhibit will receive a bronze medal.

The Prometheus Electric Company's exhibit of electric heating and cooking apparatus was awarded a silver medal.

The Automatic Electric Company took the Grand Prize for its automatic telephone exchange apparatus and telephone apparatus and appliances in general. The company had an excellent working exhibit which was used by the exposition officials to a considerable extent.

The Leeds & Northrup Co. had an extensive exhibit of resistance-measuring apparatus, potentiometers, galvanometers and curve tracers, on which it was awarded a Grand Prize.

Non-Electrical Instruments.—Keuffel & Esser Company received the Grand Prize for its exhibit of instruments of precision, philosophical instruments, etc., and a gold medal for instruments and equipment for underground surveying.

Steam Engines.—The Ball & Wood Co. had no exhibit in the Exposition proper, but its engine in the Philippine exhibit was awarded by the International Filipino Jury of the Exposition, under the direction of the Secretary of War, a gold medal of the same kind as that given by the Exposition.

Buckeye Engine Company received a gold medal for its well-known engines.

The Fleming engine, built by the Harrisburg Foundry & Machine Works, was awarded a gold medal. The engine exhibited was a tandem compound four-valve, direct connected to a Crocker-Wheeler generator.

The Phoenix Iron Works Company also made an exhibit and received from the International Philippine Jury an award of a gold medal for the compound engine exhibited in the power plant of the Philippine Government Board.

The Hooven, Owens, Rentschler Co., whose exhibit engine was described in the July number of this journal, took a gold medal.

Gas and Oil Engines.—Weber Gas & Gasoline Engine Company was awarded gold medals on its gas and gasoline engines and suction gas producers.

August Mietz received a gold medal and special diploma for his oil engine, known as the Mietz & Weiss engine.

Water Wheels.—The tangential water wheel exhibited in operation by the Abner Doble Co. was awarded the Grand Prize. This wheel, with a 100-kw. Crocker-Wheeler generator to which it was direct connected, constituted one of the units in the power-house of the intramural railway.

Steam Engineering Specialties.—The chain grate stoker of the Green Engineering Company received a gold medal. The exhibit comprised stokers in operation under boilers aggregating 3200 horse-power.

The Worthington turbine condenser outfit (International Steam Pump Company) operated in connection with a Curtis turbine, received the Grand Prize.

Weinland boiler tube cleaners, built by the Lagonda Manufacturing Company, captured a gold medal.

The Cochrane feed-water heaters and purifiers shown in the exhibit of the Philippine Government Board were awarded a gold medal, and the Harrison Safety Boiler Works also received another gold medal on the general exhibit of Cochrane heaters, steam and oil separators and Sorge-Cochrane systems of feed-water heating and purifying.

The Ashton Valve Company received a gold medal for its pop safety valves and steam gauges, exhibited in Machinery Hall.

Other Machinery.—C. W. Hunt Co. was especially fortunate in the matter of awards. Its industrial railway system received a gold medal and the Hunt electric storage battery locomotive was awarded a silver medal, which was the highest award in this class of locomotives.

Robins Conveying Belt Company received a Grand Prize for its coal conveyor equipped with distributing tripper and shown in Machinery Hall, and a gold medal for the conveyor installed in the U. S. Geological Survey exhibit.

Richardson Scale Company was awarded a gold medal for its automatic weighing machinery, which was exhibited in conjunction with the Robins conveyor system just mentioned.

E. W. Bliss Co., whose sheet-metal-working machinery is used by many manufacturers of electrical apparatus, was awarded a Grand Prize for "superiority of workmanship, smoothness of action, ingenuity of design and high quality of product" as embodied in its sheet-metal-working machines. The company took a gold medal on its arsenal machinery.

Niles-Bement-Pond Co. received a Grand Prize on the machine tools of its manufacture.

The Pratt & Whitney Co. carried off the Grand Prize and a gold medal for machine tool equipment for arsenals.

Belting.—The Shultz Belting Company received a gold medal on its "Sable" rawhide belting, belt cement, etc. We understand that this was the highest award in the belting class.

Fire Protection.—"Kilfyre," manufactured by the Monarch Fire Appliance Company, took the highest award in its class; this was a bronze medal.

◆◆◆

CONVENTION OF DISTRICT MANAGERS OF THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY.

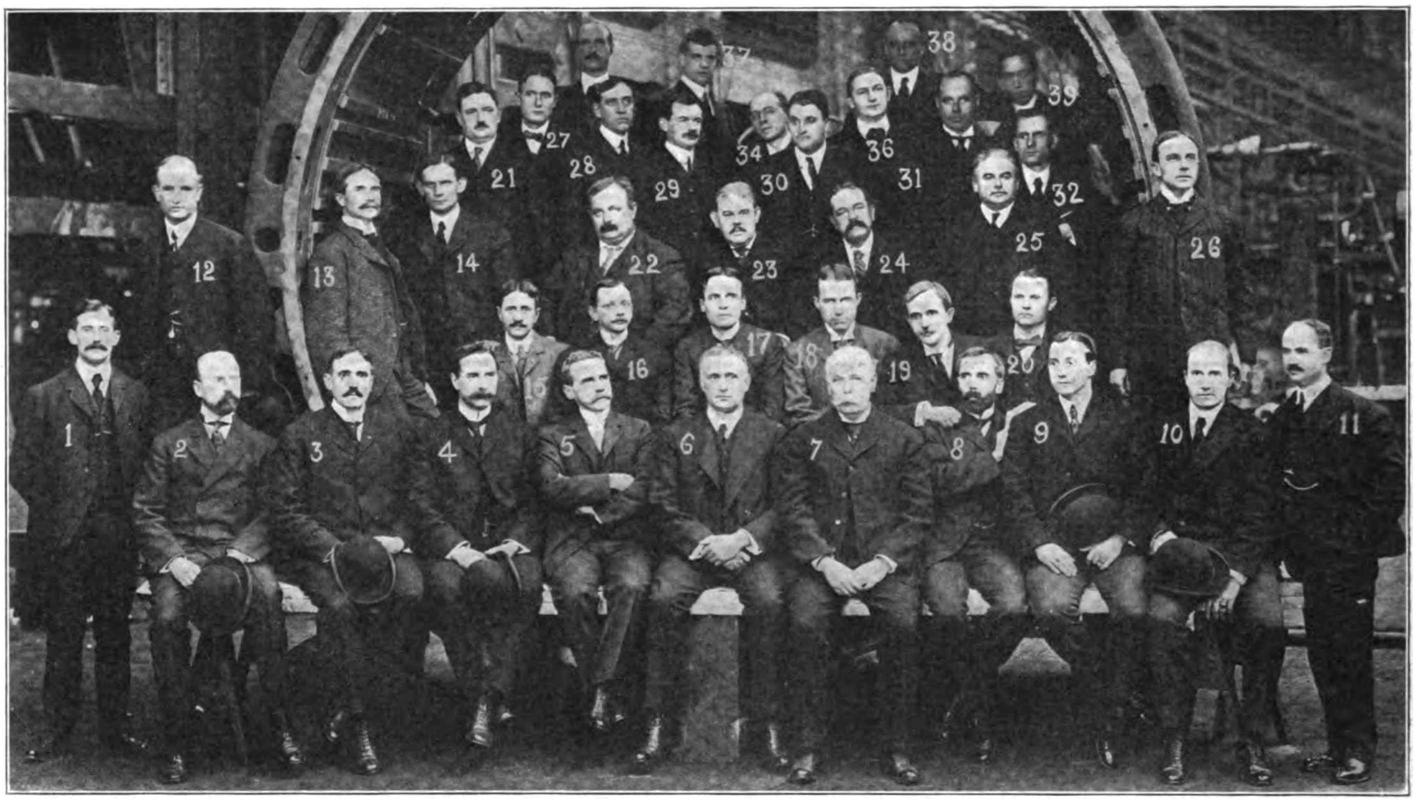
During the week ending November 19 the district managers of the Westinghouse Electric & Manufacturing Company gathered at the works at East Pittsburg and discussed plans and methods for the coming year. These conventions are annual occurrences and are productive of much good, bringing together men from all parts of the United States whose experiences are the natural outgrowth of conditions under which they labor.

Those attending the convention were Messrs. Calvert Townley, General Agent, New York; G. Pantaleoni, General Southwestern Manager, St. Louis; R. L. Warner, New England Agent, Boston; E. W. T. Gray, New York; D. E. Manson, Boston; W. S. Heger, San Francisco; F. B. H. Paine, Manager of Export Office, New York; C. W. Underwood, Buffalo; C. F. Medbury, Detroit; G. R. Dusinberre, Cleveland; W. F. Fowler, Baltimore; C. A. Bragg, Philadelphia; M. P. Randolph, Seattle, Wash.; S. J. Keese, Los Angeles, Cal.; P. N. Jones, Pittsburg; D. E. Webster, St. Louis; T. P. Gaylord, Chicago; L. M. Cargo, Salt Lake City; J. R. Gordon, Atlanta, and T. J. McGill, Minneapolis.

Throughout the convention there was evident a feeling of optimism regarding the business situation and the prospects of continued prosperity throughout the country. Mr. Heger stated that the outlook on the Pacific Coast was never better, work being plentiful and money easy. "Mining projects in California are flourishing," he said, "and they appear to have plenty of money behind them. This insures large installations of Westinghouse electrical machinery." Mr. Cargo said that the election of Roosevelt had given a decided impetus to mining development in Utah, Arizona, Nevada and New Mexico; capital which prior to that had been timid being induced to pour money liberally into dormant investments.

Mr. Gordon said: "The South will soon have the greatest boom of its history. For the past two years the cotton crop, the barometer of Southern prosperity, has been phenomenal. Business conditions reveal a greater stability and the increase of manufacturing in the South is extraordinary. Abundant water power easily available will prove an enormous boon and a producer of business for Pittsburg. Mr. Bragg said that the outlook for general industrial activity was never brighter; while there has been plenty of capital during the past year, timidity over unsettled political conditions prevented its investment. Lack of confidence has disappeared and hopeful buoyancy is observable everywhere.

Mr. Gray said that New York suffered severely the past year because of building strikes, but that since these subsided business has been good there. He thought it a foregone conclusion that business will be even better, as "cheap money is abundant and there is no lack of financial support for any legitimate enterprise." Mr. Paine,



WESTINGHOUSE REPRESENTATIVES AT THE DISTRICT MANAGERS' CONVENTION.

1. E. W. T. Gray; 2. D. E. Manson; 3. C. W. Register; 4. C. B. Humphrey; 5. C. A. Terry; 6. F. H. Taylor; 7. W. S. Heger; 8. F. B. H. Payne; 9. G. B. Griffin; 10. C. W. Underwood; 11. C. F. Medbury; 12. J. R. Gordon; 13. C. Townley; 14. M. P. Randolph; 15. J. C. Bennett; 16. S. L. Nicholson; 17. L. A. Osborn; 18. R. L. Warner; 19. G. B. Dusinberre; 20. J. E. Johnston; 21. P. N. Jones; 22. C. S. Cook; 23. W. M. McFarland; 24. C. A. Bragg; 25. S. J. Keese; 26. W. F. Fowler; 27. S. E. Webster; 28. S. H. Anderson; 29. N. S. Braden; 30. F. L. Shepard; 31. W. Cary; 32. C. F. Scott; 33. L. M. Cargo; 34. G. Pantaleoni; 36 F. F. Rohrer; 37. T. J. McGill; 38. J. W. Sterns; 39. A. Goodby.

manager of the export department, said that the outlook for foreign business has never been more promising for American manufacturers because never before were Europeans more alive to the superiority of American manufacturing methods.

◆◆◆

OPPORTUNITY FOR SALE OF ELECTRICAL APPARATUS ABROAD.

Mr. O. L. Remington, now in this country in the interests of William McLean & Co., Melbourne, Australia, will be in New York, at the Astor House, for a few days beginning on or about December 21, and desires to confer with manufacturers who wish to establish business connections in Australia. We understand that his house already represents the Bullock and Wagner Companies, as well as some other representative builders of electrical apparatus, and desires to increase its representation of American manufacturers.

◆◆◆

COMPARATIVE GAS AND STEAM PLANT DATA.

A prominent engineer of the Power & Mining Machinery Company gives the following interesting particulars concerning the economies of gas generating plants as compared with steam plants:

The yearly records of 11 electric power stations, each serving a population of 5000 or less, and of 45 stations, each serving 5000 or more, show:

The average brake horse-power developed, 1235; the average coal consumption per b.h.p. hour, 5.5 lbs.; the average cost of coal per ton, $4.30.

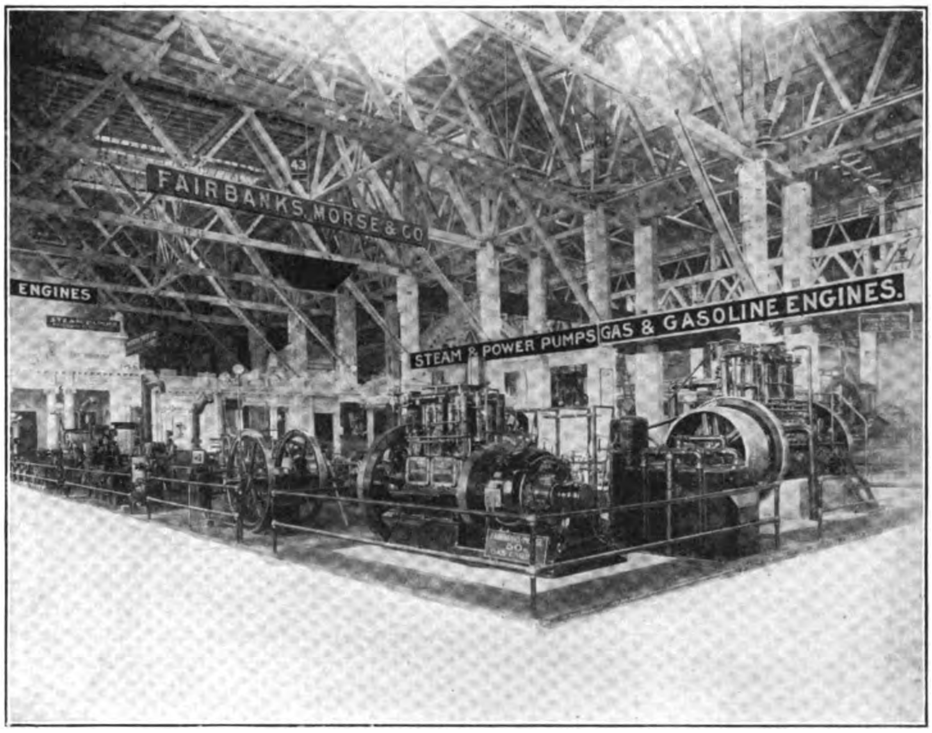
Cost of fuel in steam plant (operating 10 hours per day): 33.96 tons coal at $4.30 a ton, $146.02.

Cost of fuel with gas engines and producers: 7.72 tons coal at $4.30 a ton, $33.19.

Saving per day, $112.83; annual saving (365 days, at $112.83), $41,182.95.

EXHIBIT OF FAIRBANKS, MORSE & CO. AT ST. LOUIS.

The accompanying illustration shows a part of the exhibit made by Fairbanks, Morse & Co., in Machinery Palace at the St. Louis Exposition. The exhibit has been made especially attractive and complete, various machines being shown in operation. A 150-h.p., vertical gas engine is belt connected to a 75-kw. dynamo, and a 50-h.p. vertical engine is direct connected to a 30-kw. dynamo. Both of these machines generate current at 110 volts which is delivered to the switchboard shown in the engraving. A motor-generator set also made by the company is controlled from the switchboard and is used to convert 110-volt current to 220-volt current for power purposes. The 110-volt current was used for lighting purposes and the 220-volt current was used to drive a direct-connected motor-driven duplex double-acting water pump and a direct-connected geared hoist. Other small motors were shown in operation. The company also had on exhibition its full line of generators, and a small direct-connected generator of 6 horse-power. This latter set was shown in operation, the engine using kerosene oil and a lighting circuit supplying the load for the generator. The full line of engines and generators made by the company ranges from 2 horse-power to 150 horse-power inclusive. The exhibit was brilliantly lighted by numerous clusters and arc lights together with a double-faced electric sign. A second electric sign over one of the adjacent spaces in Machinery Hall was also supplied with current from the exhibit. The regulation of both of the large engines driving generators was especially good, the variation in the speed of the electric generators between no load and full load being a little over 1 per cent.



FAIRBANKS, MORSE & CO.'S EXHIBIT AT ST. LOUIS.

A HEROIC TEST.

Three Westinghouse 62½-kw. engine-type generators which have been in service in the basement of the New England Building, in Cleveland, Ohio, were recently subjected to a test which shows up Westinghouse construction in a very good light. A fire occurred in the basement where the generators were installed and completely burned away the insulation on the outside of the field coils; the fire department played upon these machines with six lines of hose for an hour. Within one hour from the time the water was turned off the machines, one of them was in operation and carrying its full rated load. The second machine was put in operation later, and carried its full rated load, and at the present time two of these machines are operating under the load normally carried by all three of them. The fire-proof insulation of the field coils withstood the fire perfectly even though the outer protecting coverings were entirely consumed, and the heat was so intense as to burn and blister the finish on the frames. Electrical machinery as usually constructed is scarcely expected to stand a fire and water test, but it appears that such a guarantee might have been made on these generators.

OBITUARY.

FRANK B. BRISTOL, first vice-president of the Bristol Manufacturing Company, was killed on November 21 in a collision between an automobile in which he was riding and a train of the N. Y., N. H. & Hartford Railroad, at Waterbury, Conn. Mr. Bristol's automobile was approaching a railroad crossing at too high a speed to be stopped before reaching the tracks, and in trying to spurt across before the train arrived at the crossing the collision occurred.

WILLIAM H. LAWRENCE, a well-known consulting engineer of Baltimore, Md., died on November 5 at his home in Baltimore. Mr. Lawrence was one of the pioneers in the electrical industry in Baltimore and vicinity; for several years he was identified with the firm of Davis & Watts, which subsequently became the Viaduct Manufacturing Company, and for the past few years he restricted his work entirely to consulting engineering for that company.

DR. THOMAS M. DROWN, president of Lehigh University, died at South Bethlehem, Pa., on November 16. Dr. Drown was 62 years old, and had been president of the University since 1895. He was a graduate of the University of Pennsylvania and took additional courses at Yale and Harvard in chemistry. In 1874 he became professor of chemistry at Lafayette College, Easton, Pa., and in 1885 was appointed to the same chair at the Massachusetts Institute of Technology, where he remained until he accepted the presidency of Lehigh. He was a prominent and useful member of several technical societies.

PERSONAL.

MR. THOS. L. TOWNSEND, who has been for the past two years general sales manager of Vallee Brothers Company, Philadelphia, has severed his connection with that company.

MR. DWIGHT WALLICK has resigned the position of electrician to the York Telephone Company, York, Pa., and accepted a similar one with with the Pennsylvania Telephone Company.

MR. ALLAN POLLOK has again been appointed manager of the San Francisco Gas & Electric Company, which position has been vacant since the resignation, several months ago, of Mr. J. F. Lawless.

MR. CHARLES F. BARTH, foreman of the Westinghouse Machine Company's works, has resigned that position to accept the place of foreman of the steam turbine department of the Allis-Chalmers Company.

MR. O. R. BOLMS, who has been a member of the New York Telephone Company's staff in the cable department for the past two years, has severed his connection with that company and accepted an important position with the New York & New Jersey Telephone Company.

MR. R. C. WRIGHT, who has for several years been in charge of the design of special tools and fixtures used in the manufacture of steam turbines at the Westinghouse Machine Company's shops, has resigned his position there in order to accept a similar one with the Allis-Chalmers Company, Milwaukee, Wis.

MR. EDWARD JAMES has been engaged by the Pittsburg Gage & Supply Company to travel in its interests in the South and West. Mr. James was for many years in charge of the filter department of the Burt Manufacturing Company, and will devote his attention now to the White Star oil filtering apparatus of the Pittsburg company.

MR. NORMAN K. DEVENDORF, chief operator of the Hudson River Water Power Company and formerly superintendent of this company's power house at Mechanicsville, has resigned his position with the Hudson River Company to accept a responsible post with the St. Lawrence River Power Company, Massena, N. Y. He will have charge of the company's transmission lines.

MR. CHARLES LANG, formerly on the staff of the Wheeler Condenser & Engineering Company, has accepted a position on the sales staff of the A. D. Granger Company. Mr. Lang will give particular attention to the pump and condenser departments, and will have his headquarters at the New York office of the Granger Company. This company recently acquired the agency for the Barr Pump Company, of Philadelphia.

CAPTAIN E. A. SAWTELLE, who has been identified with Westinghouse interests for several years, in both this country and England, is on the way to New York as we go to press. Capt. Sawtelle is to be married early in this month to Miss Julia Worthington, granddaughter of Mr. Henry Worthington of pumping machinery fame. Capt. Sawtelle is said to be one of the most popular Americans who has ever gone to England in connection with engineering work.

TRADE PUBLICATIONS.

GAS FOR POWER AND FUEL. R. D. Wood & Co., Philadelphia.—An octavo pamphlet containing illustrations and descriptions of gas producers built by this firm.

H-W CROSS-HEAD-PIN OILER. The Lunkenheimer Company, Cincinnati, Ohio.—A vest-pocket pamphlet containing a brief illustrated description of the oiler mentioned.

PRODUCER GAS. Wile Power Gas Company, Rochester, N. Y.—This is Section 1 of Catalogue 'A," devoted to producer gas for power and fuel, and relates to the cost and uses of producer gas,

THE POWER OF THE NEW YORK SUBWAY. Allis-Chalmers Company.—This is a handsome brochure containing some general information concerning the new subway and specific information as to the machinery supplied to the Interborough Company by the Allis-Chalmers Company.

AIR BLAST TRANSFORMERS. General Electric Company.—Bulletin No. 4391, superseding No. 4224 and containing an illustrated description of the well-known G. E. air-blast transformer. This edition includes the two-phase and three-phase transformers which have recently been developed by the company.

TOLL BOARDS. Stromberg-Carlson Telephone Mfg. Company, Rochester, N. Y., and Chicago, Ill.—Bulletin No. 12, devoted to telephone toll-boards and containing well-illustrated descriptions of the boards and their component parts. The bulletin is handsomely executed and the descriptive matter is far from perfunctory.

SOLID KNEE MILLING MACHINES. The Garvin Machine Company, New York.—A well-executed pamphlet of vest-pocket size, containing a fully-illustrated description of the latest form of extended knee with which Garvin millers are equipped. The knee is entirely closed, this construction being said to prevent all spring and chatter.

ELECTRICAL MEASURING INSTRUMENTS. The Leeds & Northrup Company, Philadelphia. —A book of standard catalogue size devoted to the resistance-measuring apparatus, potentiometers, galvanometers, curve-tracers, etc., exhibited at the St. Louis Exposition by the Leeds & Northrup Company. The book is fully illustrated and the descriptive matter is full and clear.

DISCOUNT SHEET. General Incandescent Arc Light Company, New York.—This is a discount sheet applying to all of the catalogues of the G. I. Company, but it differs from any others that we have seen in that the sections relating to the several catalogues are tinted to correspond to the color of the catalogue; the section applying to the panel-board catalogue, for example, is tinted blue, to match the color of that catalogue.

STANDARD ENCLOSED FUSES. Chase-Shawmut Company, Newburyport, Mass.—This is Bulletin No. 28, containing illustrations and price-lists of a very complete line of enclosed fuses, standard bases, and fuse contact clips. The company has adjusted its entire line of fuses and holders to conform to the National Underwriters' requirements for interchangeability of products from different manufacturers, and now has a full stock of interchangeable enclosed fuses and fittings ready for market.

ELECTRIC LIGHTING SPECIALTIES. Benjamin Electric Mfg. Company, New York.—Catalogue B-15, relating to wireless incandescent lamp-socket clusters for all classes of service. These excellent devices eliminate the use of wire within the cluster itself, the base being provided with terminals for connection to the circuit in much the same way that a ceiling rosette is connected up; all internal connections between the sockets and the terminals are made in the construction of the cluster.

BUSINESS NEWS.

BOSSERT ELECTRICAL CONSTRUCTION COMPANY, Utica, N. Y., is supplying the switchboards and panelboards for the new government laboratory at Manila, P. I.

COMMERCIAL ELECTRICAL SUPPLY COMPANY, St. Louis, has arranged to handle the telephone and switchboard business of the Vought-Berger Company in the South and West. All southwestern business will be handled through the St. Louis agency.

THE PLATT IRON WORKS, Dayton, Ohio, has bought the plant, good-will and existing contracts and orders of the Stillwell-Bierce & Smith-Vaile Company, builder of the well-known Victor turbines and Smith-Vaile pumping machinery, feed-water heaters, etc.

THE WESTERN DISPLAY COMPANY, of St. Paul, Minn., is calling attention to its "Reflectric" advertising signs. These signs are appropriate for every class of business advertising, and the manufacturers are sending out some interesting printed matter concerning them.

THE TRUMBULL ELECTRIC MFG. COMPANY, Plainville, Conn., has added to its well-known line of electrical specialties the manufacture of switchboards and panel-boards. The company has also added to its factory facilities and now is in position to handle all orders with extreme promptness.

ALLIS-CHALMERS COMPANY'S New England offices, heretofore in the Board of Trade Building, Boston, and those of the Bullock Company in the *Journal* Building have been consolidated and removed to the State Mutual Building, No. 50 Congress Street. George H. Berg is in charge of the consolidated offices.

THE W. R. EVANS ENGINEERING & CONSTRUCTION COMPANY, Cincinnati, has been organized for the purpose of doing an engineering and general contracting business, building, promoting, financing and engineering electric light and railway propositions and similar enterprises. Mr. W. R. Evans is the president of the new company.

THE BALL ENGINE COMPANY, Erie, Pa., recently closed a contract with the New York & Pennsylvania Company, Johnstown, Pa., for two 1000-horse-power vertical cross-compound Corliss engines for direct connection to electric generators. The company's business in smaller engines of both the Corliss and shaft-governor types continues brisk.

AMERICAN STEEL & WIRE COMPANY has thus far supplied to the Interborough Rapid Transit Company for use in connection with the subway system over 267,000 feet of paper-insulated and lead-encased feeder cable of 2,000,000 circular mils cross-section. This cable is made up of 91 wires, and the diameter over the lead sheathing is about 2¼ inches. The quantity of copper used in 267,000 feet is about 900 tons.

THE FORD ELECTRIC & MFG. COMPANY, St. Louis, Mo., recently bought the entire plant, good-will and outstanding business of the St. Louis branch of the Rossiter-MacGovern Electrical Company and has reorganized the plant so that its repair shops now rank among the largest and best-equipped in the Southwest. The transportation facilities are also unusually good, a spur from the tracks of the Terminal Railroad Association extending directly to the works.

ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, reports among recent contracts for "Chloride" accumulators, two three-wire batteries for the Union Electric Light & Power Company, St. Louis; a three-wire battery and an exciter battery for the Boston Edison Company; a three-wire battery for the Rochester (N. Y.) Railway & Light Company; an exciter battery for the Interborough Rapid Transit Company, New York, and a lighting and power battery for the New York Hall of Records (sold through the Chas. L. Eidlitz Company).

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has sold to J. E. Henry & Sons, Lincoln, N. H., two large induction motors for use in their pulp mill. The larger motor is a Type F machine rated at 600 horse-power and will be supplied with three-phase currents at 400 volts and 25 cycles. The motor will be direct-connected to two pulp grinders and will run at a speed of 230 r.p.m. The smaller motor is a Type C constant speed machine rated at 300 horse-power. It will also be connected to a pulp grinder and will run at a speed of 205 r.p.m. These motors are ordered in addition to a large number of machines which have been purchased from the Westinghouse Company for this paper mill. Twenty-four induction motors and four 350-kw. alternators, with exciters, switchboards, transformers and detail apparatus have been ordered, and the greater part of these have been delivered.

SHEPHERD ENGINEERING COMPANY, Franklin, Pa., is evidently not suffering from the hard times preceding the recent election. Among their most recent installations are a 600-horse-power, four-valve cross-compound engine to the Eberhard Faber Pencil Company, of Brooklyn, N. Y.; two 250-horse-power engines, each direct-connected to two generators, installed in the Russia Building, Boston, Mass., and one engine direct-connected to a Crocker-Wheeler generator, at Fort Andrews, Boston Harbor. Among recent orders booked are two engines for Brandon Hall, Beacon Hill, Boston, Mass.; three engines for the new office building of the Columbus Savings & Trust Company, Columbus, Ohio; two engines to the Arbuckle-Ryan Company, Toledo, Ohio, and one to the Joyce-Cridland Company, Dayton, Ohio. The Shepherd engine is a highly developed example of the high-speed automatic type, combining strength and rigidity with simplicity of design and economy in operation.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

SELMA.—G. H. Rettew, until recently superintendent of the Selma Lighting Company, has been transferred to the home office of the company at Philadelphia. He has been succeeded here by Mr. R. L. Ellis, of Biloxi, Miss.

OPELIKA.—Mr. S. H. Browne, who has been connected with the electric light plant in this city for the past several years, has accepted the position of superintendent of the municipal electric light plant and water works at Union Springs, this state.

ARIZONA.

PHOENIX.—The Green River Power, Land & Irrigation Company has been incorporated by P. W. Barclay and George C. Plummer. The company is capitalized at $500,000; its principal place of business will be at Phoenix, and it is proposed to engage in irrigation, the construction of canals and dams and the construction and operation of electric power plants.

ARKANSAS.

SEARCY.—The contract for the construction of the municipal electric light plant for this town has been let to the Black Hawk Electric Company, of Davenport, Iowa, for $19,105.

BRINKLEY.—The Farrell Light & Heat Company has filed articles of incorporation. The company purposes to manufacture and supply heat, light and water for the town, its citizens and corporations. The capital stock is $50,000, and the incorporators are J. J. Farrell, president; H. W. Boyle, vice-president; W. S. Kilpatrick, secretary; Patrick Farrell and Thomas J. Doyle.

CALIFORNIA.

RIVERSIDE.—The Oxhard Light & Water Company has purchased a tract of land on which to erect a new lighting plant.

STOCKTON.—James Kelly is now chief engineer of the plant of the Stockton Gas & Electric Company, and B. F. Wellington, Jr., assistant superintendent.

SAN JOSE.—The Tuolumne Electric Company has been incorporated with a capital stock of $200,000 by R. W. Hersey, C. W. Quilty, J. J. Dunne and others.

UKIAH.—The Ukiah Redwood Lumber Company, which was recently incorporated with a capital of $50,000, is making arrangements to install an electric light plant.

AZUSA.—The city has purchased the lighting plant of the Azusa Electric Light & Power Company for $2300, and the plant will hereafter be operated as a municipal plant.

ALAMEDA.—The Trustees have taken steps toward securing new machinery to be installed in the municipal electric light plant, including a turbo-generator set and an engine and dynamo.

RIALTO.—A committee of Rialto business men is reported to have asked the San Bernardino Gas & Electric Company, of San Bernardino, to extend lines to Rialto for lighting and power purposes.

GUERNEVILLE.—The Guerneville Light Company has been incorporated by W. P. Turner, O. O. Cobb and W. A. Turner, with a capital of $25,000, to construct and maintain a lighting plant and water works in this town.

OROVILLE.—Col. P. Henshaw, of Chico, has petitioned for a franchise to erect poles and string wires for the purpose of transmitting electricity for light and power purposes in Butte County. It is probable that lines will be run to Chico and Marysville.

OROVILLE.—The Tehama County Water Company has filed articles of incorporation stating the capital stock to be $1,500,000. B. A. and S. M. Steiffer are among the incorporators; the company was organized for the purpose of manufacturing and distributing electricity.

SAN LEANDRO.—The Mt. Diablo Light & Power Company has been incorporated, to furnish electric light, heat and power. The company's principal place of business will be at San Leandro; capital, $50,000. Directors: J. W. Burge, of Haywards; C. A. Jeffery, Oakland, and G. J. Clark, of San Leandro.

QUINCY.—A company has been incorporated known as the Pacific Power Company, to operate in Plumas County. It is proposed to transmit power to San Francisco, a distance of 200 miles; capital, $1,000,000. The business office of the company will be at Minneapolis, Minn. George E. Maxwell, president; George P. Darling, secretary.

VISALIA.—The Mt. Whitney Power Company is said to have purchased the rights and interests of the Bursell & Henley Power Company, on Middle Tule River, and also the stock of the Globe Light & Power Company. As soon as the right of way is finally settled the Mt. Whitney Company will install a power plant on the Middle Tule. C. H. Holley, superintendent and chief engineer, Visalia.

FORTUNA.—The Fortuna Lighting Company has been incorporated with a capital of $60,000. Directors: L. M. Hancock, Denver Sevier and D. S. Newell. The new company is the successor to the plant of the Humboldt Milling Company of Fortuna. The new company also acquires the franchise of the Milling Company for the extension of electric light and power lines into the adjacent townships.

EUREKA.—The North Mountain Power Company has about completed its power line from the plant on the Trinity River to Eureka and expects to begin supplying electricity by the first of the year. Most of the machinery has been installed and work on the sub-station here is being pushed as rapidly as possible. The building will be of sheet iron, 135 feet long by 30 feet wide and the side walls will be 26 feet high.

LOS ANGELES.—The Edison Electric Company of Los Angeles is making preparations to commence active work on its Kern River power plant the first of the year. Power house No. 2, in Santa Ana Canyon northeast of San Bernardino, has been completed, and the company expects to keep a large force of men at work at the head of the canyon preparing the site for the erection of a plant on the Clark place.

MAGALIA.—The Valley Counties Power Company, which is controlled by the California Gas & Electric Corporation, of San Francisco, has recently completed the installation of an additional dynamo with a capacity of 6000 horsepower at the De Sabla powerhouse, Centerville, eleven miles from here. This doubles the capacity of the plant, there being already in operation two machines with a combined capacity of 6000 horsepower. The water power used at this plant is secured from Butte Creek and is brought to the power house by means of a pipe line over half a mile long. The installation of the new dynamo necessitated laying another pipe line 2600 feet long and 30 inches in diameter.

TRUCKEE.—The final contracts between the Truckee River General Electric Company and the thirty-two mining companies comprising the Comstock Pumping Association have been closed. The ten-year contracts call for the delivery of electric power for draining the Comstock mines, lighting, hoisting, etc., the maximum amount being 5000 horsepower. In order to fill these contracts for additional power the Truckee River Company has prepared plans for a second electric generating plant, having double the capacity of the old one, and a new pole line thirty-two miles in length. Water will be diverted from the Truckee River and conducted to the extreme eastern end of the company's hydraulic system, where it will be utilized by water wheels operating under a head of 141 feet. If the maximum 5000 horsepower is used the rate is to be $4.50 per horsepower per month, with proportionate rates for lesser amounts. This is based on meter readings, and will save the mining companies a considerable amount of money compared with the contracts formerly existing. The pumping association will spend about $80,000 for additional 800-h.p. electric pumps, which are to be installed in the Ward shaft. This machinery will be delivered in nine months. The pumps will lift 3200 gallons per minute 1550 feet from the 3100-foot level to the Sutro tunnel. The machinery contracts will be closed at once.

COLORADO.

CANON CITY.—The Colorado Electric Power Company recently closed a contract with the Arkansas Valley Electric Company, of Florence, to furnish power for lighting and other purposes in that city, and has begun the construction of the necessary transmission lines. The new line will be run from South Canon through Chandler and Rockvale to Florence, a distance of nine miles. The work is being rushed with all possible speed and it is expected that the line will be in operation early in January. The Power Company has also secured a contract from the Victor Fuel Company, under the terms of which it will furnish power for the latter company's new Radiant coal mine eight miles south of Florence, and plans are maturing for extending the wires to that camp from the vicinity of Rockvale. The Colorado Electric Power Company already operates a successful transmission line to Cripple Creek.

ROCKWOOD.—B. F. Schmid, general manager of the Animas Canal, Reservoir, Power & Investment Company, states that the contract work on its transmission system is being pushed as fast as possible, and it is hoped that it will be in operation by May 1 next. The company expects eventually to be able to supply current within a radius of one hundred miles from Rockwood. The main power plant will be situated near this city, with an auxiliary station about nine miles south of here. The two stations will develop ultimately 60,000 horsepower. The project includes the building of a large reservoir with an ultimate capacity of 4,500,000,000 cubic feet, which will be supplied from Cascade Creek and Animas River by means of two ditches. From the reservoir the water will be carried by a four-mile flume to the bluffs of the Animas River, where a fall of one thousand feet will be obtained. It is estimated that the cost of the work will approximate $2,000,000. The equipment includes 2200-kw. generators and the current will be distributed through step-down transformers. It is stated that sufficient contracts for power have been secured from mining corporations and others to insure the success of the undertaking.

CONNECTICUT.

CANAAN.—The Berkshire Power Company has commenced work on the erection of a dam and electric power house on the Housatonic River near the toll bridge in this city. Upon the completion of this plant it is understood that the Norfolk Electric Light & Power Company whose stock was recently transferred to new stockholders, will be merged with the Berkshire Power Company, as both companies are now controlled by virtually the same people.

DELAWARE.

NEW CASTLE.—The Delaware Water & Improvement Company, of which James M. Seabury, of Philadelphia, is president, has been granted a 25-year franchise for the operation of electric light and water plants in this city. It is understood that the new concern will supplant the New Castle Water Works Company.

WILMINGTON.—The Interstate Power Company has succeeded the Wilmington City Electric Company. J. A. Rigg continues as president; Remie Remont is vice-president; S. S. Hogg, general manager, and D. L. Ott, assistant superintendent. Under its city contract the company supplies 315 2000-c.p. arc lights and 507 16-c.p. incandescent lights.

FLORIDA.

STARKE.—The Starke Electric Light & Water Company is equipping its plants with a storage battery system which will be used to run the lights in case of any trouble with the machinery at any time.

LAKE CITY.—Robert W. Adams, president of the Lake City Electric & Water Company, died recently from the effects of a stroke of paralysis after a very short illness. Mr. Adams, although a young man, was also president of the State Exchange Bank and held other important interests in this city.

WINTER PARK.—A charter has been granted to the Winter Park Electric & Fuel Company, with a capital of $25,000, to construct and operate electric plants for the generation and sale of electricity for lighting and other purposes. J. M. Cheney, H. W. Greetham and H. H. Yowell are among the incorporators.

GEORGIA.

HARTWELL.—The city has advertised for bids for an electric light plant to cost $15,000.

EATONTON.—The Putnam Mills & Power Company has been incorporated with a capital stock of $500,000. Among the directors are O. B. Nisbat and W. B. Floyd.

GREENSBORO.—The citizens have voted unanimously to issue bonds for the establishment of an electric light plant, and the new system will be installed at an early date.

NEWMAN.—It is understood that the city has decided to purchase the plant of the Newman Light & Power Company, the people having recently voted for an issue of bonds for this purpose.

QUITMAN.—For the third time the city has found it necessary to increase the capacity of its plant. With the new dynamo just installed the city is now prepared to furnish power for about 8000 lights.

BUFORD.—The election held here recently on the question of a bond issue resulted in a vote for the bonds by a large majority. The city will at once issue bonds to the amount of $2,000, part of which will be used to establish an electric light plant and water works system.

CAMILLA.—At the recent election held for the purpose the citizens voted for an issue of bonds to the amount of $20,000, the proceeds to be disbursed as follows: $7000 for the erection of an electric light plant to be owned and operated by the city, $11,000 for establishing a system of water works, and $2000 to pay off the present bonded indebtedness of the town.

MONTICELLO.—The town has recently made a contract for light with Messrs. C. L. Thompson and John M. Henry, Jr., who will immediately install an electric light plant. Under the terms of the contract the city will be supplied with forty 32-c.p. incandescent lights and five arc lights for $125.00. Messrs. Thompson & Henry also agree to make the necessary repairs and to furnish fuel and power for the water works at $150.00 a month additional.

ATLANTA.—The large power plant of the Atlanta Water & Electric Company, which has been in the course of construction for some time, has been completed at a cost of $1,350,000. The plant is operated by water power derived from Bull Sluice Shoals, near this city, and furnishes electric power to the Georgia Railway & Electric Company for operating its street railways, lighting and power plants. The equipment includes seven pairs of 2400-h.p. turbines direct-connected to 1500-kw. generators and two single turbines of 250 horse-power each.

ILLINOIS.

ANNA.—Owing to the destruction of the city's plant by fire recently, the town is without light.

MACKINAW.—The electric light plant, owned by S. A. Thompson, has been destroyed by fire.

DELEVAN.—The city recently lost its electric light plant by fire, which has left the city without light.

GIFFORD.—Reports state that William Wooldridge and W. H. Piper contemplate establishing an electric light plant here.

GENESEO.—The directors of the Geneseo Electric Light Company have voted to issue $8500 bonds to be used in installing new machinery and boilers in its plant.

GRANITE CITY.—The Granite City Light & Fuel Company has filed articles of incorporation, placing its capital stock at $200,000. W. F. Niedringhouse is one of the directors.

PAXTON.—Reports are to the effect that a movement is on foot here for the organization of a company to purchase the plant and property of the Paxton Electric & Power Company.

CHESTER.—Harvey Neville and A. G. Neuling, with others, have filed articles of incorporation for a company with a capital of $10,000. The company purposes establishing electric light and cold storage plants.

MORRISON.—Articles of incorporation have been filed by George A. Whitcomb, Ed. A. Smith and Harvey S. Green for the Rock River Hydro-Electric Milling & Power Company, Inc., with a capital stock of $50,000.

SPRING VALLEY.—The Spring Valley Lighting & Power Company has been granted a charter to construct a light, heat and power plant. The company's capital is $100,000, and the incorporators are John McFadden, R. Reichardt and H. E. Brown.

MANSFIELD.—Articles of incorporation have been filed for the Mansfield Electric Company by Messrs. E. E. Saylor, R. E. Howe and C. W. Fiske. The company's capital is fixed at $10,000 and it is proposed to erect and maintain an electric light plant.

EVANSTON.—The Evanston Interurban Railroad Company has been incorporated for the purpose of operating a street railway and an electric light and power plant. The company is capitalized at $5000. E. F. Clapp and F. J. Kinsley are interested in the project.

EAST ST. LOUIS.—At a recent meeting of the City Council the Illinois Illuminating Company asked for the passage of ordinances granted it the right to erect poles and string wires in East St. Louis, in order that it might furnish electricity for light and power purposes.

INDIANA.

HAMMOND.—The South Shore Gas & Electric Company has commenced the construction of its West Hammond system.

FRANKFORT.—The local electric light plant has been purchased by F. M. Ingler, who, it is said, contemplates making improvements in the plant to the amount of $20,000.

ELKHART.—It is reported that the Indiana & Michigan Electric Company is preparing plans for the construction of a transmission line from its dams along St. Joseph River to distribute current to Indianapolis and Louisville, Ky.

INDIAN TERRITORY.

CHICKHASHA.—The contract for the erection of the new electric lighting plant here has been let to L. Martin.

COALGATE.—The Coalgate Company has been granted a 20-year franchise for the construction and operation of an electric light plant in this town.

IOWA.

GORIN.—D. A. Frazee and J. K. Hackett have petitioned the Town Council for an electric light franchise.

RED OAK.—The Red Oak Electric Company has made application to the Council for the right to use the streets of the city.

SHENANDOAH.—The Shenandoah Artificial Ice, Power, Heat & Light Company is said to have purchased the local light plant and will make extensive improvements.

LENOX.—The Lenox Electric Light & Power Company, with a capital of $1800, has been incorporated by T. W. Bennett and others, and has been granted a local franchise.

SIOUX CITY.—The citizens voted recently to grant a franchise to E. Tilden, president of Libby, McNeil & Libby, Chicago, and Samuel McRoberts for the construction of a heating and electric light plant.

CHARLES CITY.—A. L. Dodd writes that he is interested with others in the construction of an electric light plant here to cost $25,000. Bids for the construction will probably be received about February or March.

WAVERLY.—At a meeting of the City Council it was decided to purchase the plant of the Healey Electric Light Company for $13,500. The transfer has been made and the plant will in the future be operated as a municipal plant.

KANSAS.

LAWRENCE.—Mr. George Dawes is now president of the Lawrence Gas, Fuel & Electric Light Company.

WICHITA.—The City Council has granted to the Citizens' Electric Light, Heat & Power Company a franchise for an electric light and heating plant.

COFFEYVILLE.—Arrangements have been made to sell the machinery comprising the present equipment of the municipal lighting plant and to replace the same with an entire new outfit. The capacity of the plant will be considerably increased and the service improved. E. L. Rossiter is superintendent and purchasing agent and P. G. Walker is chief engineer and electrician.

KENTUCKY.

FORDSVILLE.—The Board of Trustees has passed a resolution for the building of an electric light plant and it is thought that the construction work will soon be under way.

UNIONTOWN.—Mr. G. F. Cecil is manager and purchasing agent of the Uniontown Electric Light Company. The company has the city lighting contract and runs on an all-night schedule.

PADUCAH.—It is proposed to install a new electric light plant at a cost of $20,000. The present one has been in operation since 1894 and much of the equipment needs replacing. It is also inadequate to meet the increased demands being made upon the plant, and it is deemed advisable to install a new outfit.

LOUISIANA.

PLAQUEMINE.—Victor M. Garber, of Shreveport, has been granted a franchise for the establishment of an electric light and power plant. Arrangements have been made for the purchase of the necessary building site in the rear of the water works plant and work will soon begin on the construction of a brick building in which to house the plant. According to the terms of the franchise, the town will be supplied with forty 1500-c.p. arc lights at an annual cost of $2400. Mr. Garber will also run the water works under a special agreement with the town authorities.

MAINE.

WILTON.—The Wilton Electric Light & Power Company has been incorporated with a capital of $10,000. A. V. Adams is president, and C. N. Blanchard, treasurer, both of this city.

LEWISTON.—This city and Auburn are now being furnished with light from the new 10,000-h.p. plant which has been in course of construction for the past two years at Deer Rips.

BLAINE.—The Mars Hill & Blaine Electric Light Company has been organized to construct and maintain an electric light plant. The capital of the company is placed at $10,000. Almon O. Nutter, of Mars Hill, is president, and George W. Young, of Blaine, is treasurer.

SOUTH WINDHAM.—The Mallison Electric Light & Power Company, of this city, has been granted permission to extend its lines throughout the city for commercial lighting purposes. Work on the erection of poles and cables will begin at once. The franchise also includes Gorham and Little Falls. B. H. Elkins is superintendent of the plant.

ELLSWORTH.—Reports are heard of the formation of a new lighting company which will apply for a charter at the next session of the Legislature for lighting and heating this city and the towns of Trenton, Eden, Mount Desert, Tremont and Gouldsboro in the County of Hancock. T. F. Moran and Charles B. Pineo, both of Bar Harbor, are said to be the promoters of the project.

MARYLAND.

BALTIMORE.—The plant of the American Lighting Company is said to have been damaged by fire to the extent of $2500.

BEL-AIR.—Plans have been completed by the Susquehanna Electric Company for the construction of a large electric power plant on the Susquehanna River, and it is expected that active work will commence soon. It is proposed to erect a plant, the cost of which is estimated at $9,000,000, for the purpose of supplying electricity for manufacturing, lighting and power purposes. B. H. Welch, of Philadelphia, is president of the company.

BALTIMORE—The Baltimore Electric Power Company, the organization of which was reported in these columns last month, has perfected its plans for the construction of its lighting and power plant. The building and machinery contracts have been let, and it is hoped to have the plant in operation by the middle of next summer. The plant will be equipped with Westinghouse-Parsons steam turbines, and a storage battery system will be installed as an additional safeguard against any interruption of the service. The officers of the new company, who are also officers and directors of the Maryland Telephone & Telegraph Company, are as follows: President, D. E. Evans; treasurer, R. F. Bonsall; secretary, W. T. Spring. Pending a permanent organization, the directors are: H. W. Webb, D. E. Evans, John T Stone, W. T. Burroughs, R. F. Bonsall W. T. Spring and George R. Webb.

BALTIMORE.—The United Electric Light & Power Company announces that plans have been consummated for the erection of a large power plant. The company expects to spend about $1,000,000 for the property, building and equipment. A site of 22 acres immediately adjoining the city and having a water front of about 1000 feet, has been purchased from the South Baltimore Company. The plant will have an initial capacity of 13,000 horsepower, but will be planned to develop ultimately 50,000 horsepower. It is hoped to have the plant completed within a year. At present the United Electric Light & Power Company receives its power from the United Railways & Electric Company and distributes it through its own transformer station in McClellan Street. This station, together with the Monument Street and Penn Street steam-driven stations, will be connected by underground cables with the new waterfront station upon its completion.

MASSACHUSETTS.

MERRIMAC.—The municipal lighting and water plant has been completed, and the town now has a system which is efficient and up-to-date.

WEBSTER.—Up to the present time the town has been lighted on a midnight schedule, but the Council has voted for an all-night service and has made an additional appropriation for the purpose.

WARREN.—Work on the addition to the power station of the Consolidated Company here progresses rapidly. The building will soon be ready to receive the machinery and it is hoped to have it in operation before many weeks.

LEXONDALE.—The Washburn Electric Company has been incorporated, with a capital of $6000, by W. H. Washburn, L. H. Hubin and T. E. Moat, of North Adams, to develop a water power for the purpose of lighting the streets and public buildings by electricity.

WEST SPRINGFIELD.—Much interest is manifested in the question of municipal ownership of the electric lighting plant here. The proposition was voted down at a recent town meeting, but the citizens have called a mass meeting for a further consideration of the matter.

GREENFIELD.—The Greenfield Electric Light & Power Company is now furnishing power for the street railway company from its recently completed plant at Garner Falls and is also lighting the city from the same source. Officers of the company believe that it will not be long before it will be necessary to provide additional facilities for supplying light and power in order to keep pace with the demands. The company has petitioned for a franchise to erect poles and string wires for lighting Deerfield and South Deerfield.

HOLYOKE.—At the annual meeting of the Holyoke Water Power Company stockholders the following Board of Directors was chosen: C. M. Beach, J. J. Goodwin, Francis Goodwin, C. E. Gross and D. W. C. Skilton, of Hartford; S. D. Smith and L. L. Willcutt, of Boston; and Frederick Harris and A. W. Damon, of Springfield. The directors who have the matter of the new electric power plant in charge have organized and are considering preliminary plans for the construction of the plant.

MICHIGAN.

DETROIT.—The new $6,000,000 plant of the Detroit Edison Company is now nearly completed. It is already furnishing light to the western portion of the Edison Electric Light Company's subscribers.

FLINT.—The following are the officers of the Flint Light & Power Company: President, J. E. Durham; vice-president, J. J. Hurley; secretary and treasurer, A. G. Bishop; superintendent and chief engineer and electrician, F. A. Beard.

NEGAUNEE.—The Negaunee & Ishpeming Street Railway & Electric Company purposes increasing the capacity of its electric light plant by the addition of two 180-kw., 2300-volt, 60-cycle dynamos, together with an engine for same.

BENTON HARBOR.—Reports state that plans have been perfected by Charles A. Chapin, representing a water power company, for the transmission of electrical power from the dam at Buchanan to the twin cities. The cost of the dam is estimated at $750,000.

MINNESOTA.

MONTGOMERY.—J. E. Anderson and S. A. Votapek have petitioned for a franchise for an electric light plant.

MINNEAPOLIS.—The Joyce-Pillsbury Co. has been incorporated to establish an electric lighting plant. The company has a capital of $100,000 and numbers among its organizers N. C. Ackley and F. C. Goddard.

WINONA.—Henry M. Lamberton has secured a franchise for the Minnesota Light & Power Company to erect a large electric light and power plant on Rollingstone Creek at Minnesota City. Water power which formerly operated two flour mills has been purchased, and in addition to this a steam plant will be erected. It is proposed to furnish electricity for commercial lighting and power in this city and the surrounding towns and villages. It will also furnish the power for several proposed trolley lines, one of which has already been surveyed.

MISSISSIPPI.

YAZOO CITY.—R. C. Rimmer has resigned his position as chief electrician at the city light, water and sewerage plant to accept a position as superintendent of the electric light and water works at Clinton.

VICKSBURG.—The Vicksburg Water Power Company advertises a proposed amendment to its charter and it is given out that an electric power plant with a capacity of 300 horsepower will be added to the water plant. Manager Crumpler states that he will be in the market to furnish light and power by February.

MISSOURI.

JOPLIN.—The municipal lighting plant and the headquarters occupied by the East Joplin Fire Company have been destroyed by fire. The loss, it is said, will exceed $60,000.

SPRING VALLEY.—The Spring Valley Lighting & Power Company has been incorporated by John McFadden, Harry N. Brown and others. The company's capital is $100,000.

KANSAS CITY.—The Fort Scott Light & Fuel Company, of Kansas City, has filed articles of incorporation, with a capital of $150,000. The incorporators are J. B. Levy, of Garnett, Kan.; C. C. Nelson, of Fort Scott, and others.

JEFFERSON CITY.—The citizens have voted to grant a franchise to the Chicago syndicate which recently purchased, through its representative, W. N. Horner, the plant of the Jefferson City Light, Heat & Power Company for $80,000. The new owners propose to rebuild and enlarge the plant.

MONTANA.

KALISPELL.—Jeremiah Miller and others have formed the Montana Water Power & Electric Company with a capital of $2,000,000 to construct a power plant and a trolley line.

PHILLIPS.—The Papoose Mining Company has been incorporated to operate in Kings Gulch, Chouteau County, and build plants for the generation and transmission of electric power to be used at mines, mills and smelters. The company's capital is $20,000 and the directors are Charles Whitcomb, of Zortman; Ben D. Phillips, of this city; Robert J. Coburn, of Brookside, and William F. Word, of Helena.

HAVRE.—The plant of the Havre Electric Light & Telephone Company has been sold to Turner & Hebgen, of Butte, who have filed articles of incorporation for the Havre Electric Company, having a capital stock of $100,000. The new company will remodel the plant and install sufficient new machinery to double its capacity. A steam-heating station will also be installed in connection with the plant and the mains are now being laid through the principal streets in the business section of the city.

NEBRASKA.

ASHLAND.—The Ashland Light, Mill & Power Company has filed articles of incorporation, showing a capital stock of $15,000. C. H. Brown, J. C. Ralsbock and F. E. White are the incorporators.

PLATTSMOUTH. — The Nebraska Lighting Company, a new organization with a capital of $100,000, of which Charles G. Parmele, of this city, is president, has purchased the property of the old Plattsmouth Gas & Electric Light Company. The system is to be practically rebuilt and the city is promised a first-class light service, such as it has not had for some time.

ARLINGTON.—A new light plant is being installed here at a cost of $5000.

KEARNEY.—R. E. Frey is now secretary and treasurer of the Northwestern Electric Heat & Power Company.

LINCOLN.—Contracts have been awarded for constructing the electric light plant and work will begin at once.

NEW JERSEY.

WEEHAWKEN.—The Weehawken Contracting Company, who recently secured the thirty years contract for lighting this township, has completed the changes necessary to fulfill the contract and the town is now lighted from the company's plant.

IRVINGTON.—The feasibility of municipal ownership of a lighting plant for Irvington is being widely discussed. A committee has been appointed to secure information regarding the probable cost of a system, and a thorough investigation of the matter will be made.

LONG BRANCH.—The Elberon Water & Light Company has filed articles of incorporation, fixing the capital stock at $150,000. The incorporators are Raymond S. Dodds, James Loux and William J. Maccohl, all of this city. The company purposes constructing and operating a water works system and an electric lighting plant.

NEWARK.—At a meeting of the Board of Directors of the Public Service Corporation held recently at its office in the Prudential Building, an issue of $7,250,000 of 5 per cent, 5-year collateral trust bonds of the corporation was authorized. The money received from the sale of the bonds is to be used in improvements throughout the various systems of the corporation. The trolley, gas and electric light plants are to be enlarged and improved.

NEW YORK.

WATKINS.—Bonds to the amount of $20,000 have been sold for the construction of a municipal electric light plant.

ONEIDA.—The Board of Public Works is advertising for bids for lighting the streets and public buildings by electricity for a period of either two or five years.

NORTH TONAWANDA.—The question of constructing a municipal lighting plant is under discussion and will probably be submitted to the people.

TANNERSVILLE.—The Tannersville Electric Light & Power Company has been recently organized and expects to be ready to supply electricity to both Hunter and Tannersville by June 1, 1905.

NEWARK.—A contract has just been entered into with the New Light, Heat & Power Company by the city for lighting the streets during a period of five years at $85 per 2000-c.p. arc lamp per year.

ONEIDA.—Dewitt C. Hadcock, C. E., of this city, states that bids will probably be received about January 1 for the construction of an electrict power plant at Limekiln Falls, to cost about $125,000.

SYRACUSE.—The stockholders of the Syracuse Lighting Company have authorized the placing of an order for a new battery of boilers at the electric light plant. The new equipment will cost $25,000.

WESTCHESTER.—Under the management of the New York & Westchester Lighting Company, which now controls the Westchester Lighting Company, extensive improvements in the system of the latter company are contemplated.

TOTTENVILLE, S. I.—The Tottenville Lighting Company has been incorporated to operate in Richmond County. The directors of the company, which is capitalized at $25,000, are W. E. Cook, W. H. Gahagan and J. F. McCarthy, of Brooklyn.

LIVINGSTON MANOR. — The Livingston Manor Electric Company has been incorporated to manufacture electricity. The capital is said to be $32,000 and among the incorporators are V. A. Finch and George S. Wollson, both of this city.

TANNERSVILLE.—The Schoharie Light & Power Company has filed articles of incorporation with a capital of $40,000. C. E. Hewitt and M. G. Hubbard, of Chatham, N. J., and H. A. Heyn, of New York City, are among the directors.

KIRKLAND.—The Oriskany Light & Power Company has secured a franchise from the Town Board to erect poles and string wires for the transmission of electricity for power purposes. The company expects to construct a concrete dam at Millburn very shortly.

GOUVERNEUR.—The Village Trustees have contracted with the Oswegatchie Light & Power Company to light the village for five years at $60 per arc light per year for the first two years for midnight service only, and at $75 per light per year for the remaining three years on an all-night schedule.

CLIFTON SPRINGS.—The various contracts for the new electric light plant to be erected here have been let and the work has been commenced and will be pushed as fast as possible. Nearly all the poles for the eight miles of circuit have been received and the work of setting them will begin at once.

PENN YAN.—The power house of the new municipal electric plant at the water works pumping station has been completed and the machinery is being installed. The 600 poles required for the lighting circuit have been set and the work of stringing the wires is nearing completion. It is expected that the plant will be in operation by December 15.

SARATOGA SPRINGS.—The Saratoga Gas, Electric Light & Power Company has secured the contract for lighting the streets and public buildings for four years on the following terms: $90 per light per year for 2000-c.p. arc lights, $25 per year for 20-c.p. gas lamps, and for public buildings gas is to be furnished in 16-c.p. lights at $1.50 per thousand cubic feet.

BROCKPORT.—The Albion Electric Light, Power & Gas Company is now prepared to furnish electric power and light to this village from its Waterport power house over a 25-mile transmission line. The system has been in operation for nearly two years and the service so far as utilized has been satisfactory. The company furnishes power for A. Tooley & Co.'s planing mill here.

NORMANSVILLE.—The Albany Electric Power Company purposes expending $100,000 in improvements in the immediate future. The office of the company is located in this place and William H. Slingerland, Jr., is president and Charles W. Bentley, secretary. The company owns water rights along the Normanskill Creek which it is proposed to develop for the operation of an electric power plant.

BUFFALO.—The International Current Power Company has been incorporated by Henry Lewis, Edward Delahunt and Thomas McDonald, of Buffalo. The company is capitalized at $100,000 and will manufacture a newly patented water wheel. It is said, however, that as soon as a site can be selected a power plant will be erected also for the generation of electricity which will be furnished to the public for heating, lighting and power purposes.

SCOTTSVILLE.—Merton E. Lewis and Henry C. Brewster, of Rochester, and Isaac W. Salyerds and David C. Salyerds, of Scottsville, have organized the Scottsville Electric Light & Gas Company for the purpose of generating and distributing electricity in the towns of Scottsville, Caledonia and Rush. The concern is capitalized at $20,000 and will also manufacture and sell artificial gas in addition to supplying natural gas if it can be obtained in the vicinity of the three towns.

MIDDLETOWN.—The properties, rights, privileges and works of the Orange County Gas & Electric Light Company of this city, were sold at foreclosure to Philip N. Jackson, of Newark, who formerly owned a controlling interest in the company, and who represented himself and other bondholders. The Neversink Light & Power Company claims the transformers, switches and other high-potential apparatus used at the electric plant which has been installed since that company has procured its power from the Neversink Company's power plant at Cuddebackville. Mr. Jackson states that the new company will begin an aggressive business policy with the intention of giving the best possible service at reasonable rates.

ROCHESTER.—Measuring instruments have been purchased by the city for the purpose of testing the quality of the light supplied by the Rochester Railway & Light Company. The question of changing from open to enclosed arc lights for the street lighting system is being discussed and the city engineer was asked to make a report on the various points involved. This report gave in detail reasons for making the proposed change. Among others a comparison was made between the outages of the enclosed arcs and the open arcs, taken from the reports of the Police Department for the first seven months of the year 1903, as follows: Total number of arc lights, 2190. Total number reported out over one-half hour, 2106; an average per night of 8.67, or forty one-hundredths of one per cent. During the same period there were 614 enclosed arcs. Total outages reported for the same time, 120; an average of 0.50 lamps per night, or eight one-hundredths of one per cent. The percentage of outages of the enclosed arc was therefore a little less than one-fifth of that of the open arc.

NORTH CAROLINA.

MT. OLIVE.—William Maxwell, J. W. Williamson, and others, recently organized and incorporated the Mt. Olive Light & Power Company, with a capital of $100,000. The contract for constructing the company's proposed plant has been let to the Standard Electric Company, of Charlotte.

FAYETTEVILLE.—The Cape Fear Electric Power Company has about completed its dam near here. The dam is 1500 feet long, and backs up the water for twelve miles. A number of cotton mills and manufacturers, as well as the new cotton mill to be built by the company at Fayetteville, will make use of the new power.

GOLDSBORO.—The city electric light plant is undergoing some greatly needed repairs under the supervision of Superintendent John S. Dortch. For some time past the street lights have been unsatisfactory, owing to the fact that the boilers would not generate sufficient steam to carry the lighting load. Two new 200-h.p. boilers have been installed in place of the old ones, which nearly doubles the boiler capacity of the plant, and the service has been much improved.

SALISBURY.—Reports are to the effect that the work of developing the enormous water power available at the "Narrows" on the Yadkin River, about eighteen miles from this city, will be resumed and pushed to rapid completion. C. L. Whitney, president of the Whitney Reduction Company, and the company's secretary, together with a company of surveyors and contractors, were here recently with a view to ascertaining just what material and other requirements would be necessary for the completion of the plant. It is estimated that the work will cost about $5,000,000.

NORTH DAKOTA.

FARGO.—The contract for lighting the streets and public buildings for one year has been awarded to the Union Light, Heat & Power Company, of this city, for $8000.

OHIO.

ZANESVILLE.—The Board of Public Service has called for bids for lighting the streets of the city for a period of one year.

MARTINS FERRY.—Bids have been called for by the Board of Public Service for furnishing a 425-h.p. engine to be installed in the municipal plant.

LEXINGTON.—An ordinance for the construction of a new lighting plant has been passed by the Council and the franchise granted to H. F. Smith.

NORWALK.—It is proposed to let the contract for lighting the city for ten years. Plans and specifications can be procured by writing to the City Clerk.

CANTON.—Anthony Howells and William L. Davis, with others, have organized the Citizens' Heat, Light & Power Company. The company is capitalized at $100,000.

DAYTON.—The Dayton Electric Light Company is perfecting plans for placing all its wires in underground conduits. This improvement will cost probably $100,000.

CLEVELAND.—Articles of incorporation have been filed by C. L. Denton, A. Lewenthal, H. L. Caldwell, and others, for the Cuyahoga Light & Power Company, with a capital stock of $25,000.

CHESTERHILL.—The Chesterhill Fuel & Light Company has filed articles of incorporation, stating its capital stock to be $16,000. Carl Patterson and R. G. Mains are among the directors.

NEWARK.—The city was without light for a short time recently owing to an accident at the municipal light plant. The large pulley burst and necessitated overhauling considerable of the machinery.

COLUMBUS.—The new lighting plant, for which bonds to the amount of $65,000 were recently issued, will be in operation by the 15th of January, according to Superintendent Wilcox. The plant will furnish current for 1800 arc lights.

CLEVELAND.—Plans are being discussed by the Board of Public Service, pending the annexation of South Brooklyn to the city, whereby the Brooklyn lighting plant may be used as a nucleus for a large municipal lighting plant for the entire city. The proposition to erect such a plant was voted down by the Council last winter. The South Brooklyn works were erected on a bond issue of $30,000, and it is claimed that $150 a month has been saved since the installation of the plant.

OKLAHOMA TERRITORY.

GUTHRIE.—The Guthrie, Fairview & Western Railway Company is contemplating the building of a modern electric lighting plant.

OKLAHOMA CITY.—The City Council has passed an ordinance granting a franchise to F. C. French and A. B. Crockett to operate an electric light, power and heating plant.

OKLAHOMA CITY.—Articles of incorporation have been filed by the Territorial Engineering Company, organized to construct and operate street railways and electric light and gas plants, with headquarters in this city. The company's capital stock is $25,000 and the incorporators are G. W. Burke, F. H. Peckham and H. L. Cunningham.

OKLAHOMA CITY.—In the recently effected reorganization of the Oklahoma Gas & Electric Company, the following officers and directors were elected: C. B. Ames, president, Oklahoma City; H. M. Byllesby, Chicago, vice-president; D. T. Flynn, Oklahoma City, secretary; A. H. Grimes, Guthrie, treasurer, and Rufus C. Dawes, Chicago; Samuel Insull, Chicago, and H. M. Newton, Sparta, Wis., directors; R. J. Graf, Chicago, assistant secretary and treasurer. H. M. Byllesby & Co., Chicago, were retained as engineers for the company. The company has issued bonds to the amount of $1,000,000, the proceeds of which will be expended in improving and extending the plant.

GUTHRIE.—The Guthrie Electric Light & Power Company has been incorporated with a capital stock of $150,000. The new company has acquired the stock of the Electric & Gas Light Company, the old light concern, which will be merged into the Guthrie Electric Light & Power Company. The plant will be enlarged and improved. The directors are Thomas H. Smith, of Denver; J. R. Cottingham and U. C. Guss, of this city. The company has been granted a twenty-year franchise by the Council, under the terms of which the city is to be furnished with free lights for the fire stations and city hall, making a total of 94 incandescent lights supplied gratis, besides a large arc light at the rear of fire station No. 1.

OREGON.

DALLAS.—Articles of incorporation have been filed by the Dallas Light & Power Company, with a capital stock of $1000. Harry V. Gates and D. P. Stouffer, with others, were interested in the organization of the new concern.

LA GRANDE.—The La Grande Water Storage Company is perfecting plans for the construction of an electric light plant which will cost in the neighborhood of $100,000.

MEDFORD.—A new company under the name of the Southern Oregon Power Company has been organized to do business in the Rogue River valley in the southern part of the State. The capital stock is fixed at $500,000. Jesse W. Churchill, of Yreka, Cal., is president of the company, and Alexander J. Rosborough, of Oakland, Cal., is secretary. The dam and power house at Gold Roy, on Rogue River, are finished and the power line is already built to Medford. The company hopes to complete the entire project in six months and expects to find a ready market for its output in the mines and lumber districts and for irrigation purposes. It will also light the town of Jacksonville, it is said.

PENNSYLVANIA.

DANVILLE.—The Borough of Danville is issuing $20,000 worth of bonds for the construction of an electric light plant.

WOMELSDORF.—The citizens have voted in favor of issuing $8000 bonds for the establishment of an electric light plant.

BEAVER SPRINGS.—The Beaver Springs Electric Light Company has filed articles of incorporation fixing its capital stock at $6000.

PITTSBURG.—The Wilkins Electric Power Company, with a capital of $5000, has been incorporated by R. T. Russell, J. G. Frazer and others.

ABERDEEN.—The question of bonding the town for $8000 for the purpose of installing an electric lighting plant was carried at the recent election.

PENN.—The Taylor Electric Power Company, organized by J. G. Evans, R. T. Frazer and others, has filed articles of incorporation with a capital stock of $5000.

WEST CHESTER.—The Borough Council is said to have renewed the contract with the Edison Electric Illuminating Company for lighting the streets of the town for a period of five years at $10,055 per year.

PHILLIPSBURG.—The Electric Light Company has secured the contract for lighting the streets by electricity for a term of five years at $80 per light per year and $10 per light per month for the borough buildings.

TELFORD.—A charter has been granted to the West Telford Electric Light & Power Company for supplying the borough and adjacent territory with electricity for light and power purposes. Morris A. Clymer, of Sellersville, is one of the incorporators.

BRADDOCK.—Bessemer Light & Power Company has been incorporated by J. G. Frazer, J. G. Evans, R. T. Russell, and others, who are also interested in the Taylor Electric Company of Penn Township. This company, like the other, is capitalized at $5000.

MAHAFFEY.—Parties associated in the iron works plant here are said to be interested in the Mahaffey Electric Company, capitalized at $5000. The plant will be operated in connection with the iron plant. The Borough authorities have agreed to take a minimum number of street lights for five years.

PITTSBURG.—Mayor W. B. Hays has signed the ordinance granting a franchise to the Duquesne Light Company. The company proposes to install a plant at an estimated cost of $2,500,000, and construction work will begin at once. Robert C. Hall is president, and S. P. Austin, secretary. The same interests which control the Pittsburg & Allegheny Telephone Company are said to be in control of the Light Company.

McKEESPORT.—A deal which has been pending here for some time has been consummated in the consolidation of the Tube City Brewing Company, the People's Ice, Light & Storage Company and the People's Brewing Company. The new corporation will have a capital of $1,500,000. The Tube City Brewing Company is already in operation, the People's Ice, Light & Storage Company will be ready for operation within sixty days, while the People's Brewing Company has secured a charter and was owned by the stockholders of the storage company. It is the intention to manufacture electricity for lighting and general power purposes.

MONONGAHELA. — Extensive improvements are in course of construction at the plant of the Monongahela Electric Light Company, which have necessitated the building of an addition to the plant. A new 200-h.p. Heine safety boiler has been installed in place of the 75-h.p. boiler formerly in use; a new stack 100 feet high also will be put up, and new pumps, heaters and arc lights have been installed. It is understood, however, that these repairs are only temporary, as it is the intention of the company to erect a new station sufficiently equipped to supply both lighting and power service. William Ewing, Sr., superintendent of the plant.

TROY.—The Council has made a contract with the Troy Gas, Power, Heat & Electric Company, by the terms of which Troy will soon have a first-class system of public and private electric lighting. The cost to the village for an all-night, every-night service, from nineteen 2000-c.p. arc lights will be $1500 a year for a period of ten years. Twelve hundred and fifty dollars was paid the old company latterly for seventeen lights run until midnight on a moonlight schedule. The plant will be located just off Canton Street, on part of the woolen mill property, and will consist of a 160-h.p. boiler made by the E. Keeler Co., of Williamsport, and fitted with a water heater and automatic pump or injector, a Hamilton Corliss engine of 160 horse-power, and a 2500-light Warren alternating-current dynamo. The engine and dynamo will be located in the engine house now on the lot. A new brick building will be erected at once for the boiler.

SOUTH CAROLINA.

ANDERSON.—A charter has been granted to the Piedmont Electric Company, with a capital of $25,000. The incorporators are E. S. Moorer, G. W. Evans and H. H. Watkins.

WALHALLA.—W. B. Frink, of New York City, and James Thompson and W. J. Stribling, of Walhalla, have organized a concern known as the Oconee Water, Light & Power Company. At present the capital stock of the company is $5000, but under the charter it may be increased to $250,000. This probably will be done shortly, as it is proposed to construct a plant which will cost from $100,000 to $120,000.

CHARLESTON.—A charter has been issued to the Broad River Light & Power Company, organized by local parties and capitalized at $1,000,000. Among others interested in the new corporation are J. L. David, J. H. Dingle and Walter H. Green. Water rights have been purchased at points above and below Lockhart Shoals, on Broad River, near this place. It is the intention to erect a dam above the shoals and pour the water through the old State canal, which was built before the war to enable boats and cotton rafts to go around the shoals. Below the site of the Lockhart mills a power house will be erected, and the electricity thus generated will be transmitted to various parts of the state.

SOUTH DAKOTA.

SIOUX FALLS.—An important transaction has just been consummated, involving the transfer of the local electric light plant, the dam in Sioux River, and what is known as Cascade mill, all being the property formerly of the Cascade Milling Company. The new owners have assumed control of the property; they are Pitt Curtis, a banker of Norwalk, Ohio, and Arthur Huntington and W. G. Mack, of Omaha. A company has been organized with Mr. Huntington as president; Mr. Curtis, vice-president, and Mr. Mack, secretary and treasurer.

TENNESSEE.

DYER.—The new plant of the Dyer Electric Company has just been completed, and the town is again lighted. The old plant was burned recently, and no effort has been spared to rebuild it with as little delay as possible.

SPRINGFIELD.—Work on the new electric lighting plant is progressing rapidly. When it is completed, the Council will be prepared to accept the proposition recently received from Adairville, Ky., twelve miles distant, to furnish lights for that town.

KNOXVILLE.—The following are the present officers of the Knoxville Electric Light & Power Company: President and manager, C. H. Harvey; vice-president, A. H. Rutherford; secretary, Leon Fender; treasurer, H. L. Bunn; superintendent, P. E. Mitchell; chief engineer, James Link; chief electrician, H. M. Moses.

JACKSON.—The Jackson Light & Power Company is the name of a new corporation with a capital stock of $25,000, which proposes to erect and operate an electric power plant in Jackson. It is claimed the present plant owned by the Jackson Street Car Company is not sufficient to meet the increased needs of the growing city. The present company has an exclusive privilege from the city, but the new company has asked for a franchise and an ordinance to that effect has passed one reading of the Board of Mayor and Aldermen, and under the rule will lie over till a subsequent meeting. Among the names of the incorporators of the new company are F. B. Fisher, I. B. Tirgrett, G. S. Baird, A. K. Kobe, E. L. James and John W. Buford.

CHATTANOOGA.—The Council has accepted a new contract from the Chattanooga Electric Company for lighting the city for five years at the rate of $6.49 per arc light per month, or $77.89 per light per year. This will permit the board to place twenty additional street lights with an expenditure of the same amount as under the present contract. With the same number of lights as used at present, 226, the city will save over $1600 per year for the next five years. However, additional arc lamps are needed and several will probably be ordered in the near future. By the terms of the contract the Chattanooga Electric Company will at once equip all street lighting circuits with the new alternating current lights. There are two circuits now in use. The others are to be completed within ten days after the company is officially notified that the contract has been entered into by the municipal authorities.

TEXAS.

EL PASO.—Mr. H. T. Edgar is now vice-president and manager of the International Light & Power Company.

LONGVIEW.—The Longview Ice, Light & Bottling Company will shortly install a new high-speed automatic engine.

CARTHAGE.—J. C. Whitney, proprietor of the electric light plant here, contemplates a complete reconstruction of the lines.

COOPER.—The Cooper Light Manufacturing Company is now known as the Cooper Electric Company, of which James W. Hockaday is proprietor.

TEXARKANA.—The Texarkana Gas & Electric Light Company, of Texarkana, Ark., will install in its plant here a new direct-connected alternating-current generator and Corliss engine.

PITTSBURG.—J. F. Allbright is manager and purchasing agent of the local plant of the Arkansas Consolidated Ice & Coal Company, of Marshall; M. R. Buchanan is chief engineer anl electrician.

DUBLIN.—George House, who has had charge of the plant of the Dublin Light & Power Company for several years, has moved to Baird and taken charge of the Baird Electric Light Company's plant. He succeeds J. B. Miller, superintendent, who has returned to Llano, this state.

DALLAS.—Bids will be received until December 6 for lighting the city, as follows: To furnish on a five-year contract from 350 to 600 arc lights, moonlight and all-night schedule each, and for plans and specifications for a lighting plant for the city with a capacity of from 500 to 1000 arc lights; also separate bids for putting in the power plant, the lighting machinery and the poles, lines and lamps thereof.

UTAH.

MILFORD.—J. W. Clark, of La Porte, Ind., is said to have secured the contract to light this town with electricity.

OGDEN.—The American Falls Canal & Power Company has been incorporated to operate in Bingham and Logan Counties. The company's capital is $500,000. Lyman Skeen is president and J. J. Brummitt, secretary.

VERMONT.

BURLINGTON.—The city expects to have its new municipal lighting plant in operation some time in February. The power house is nearly ready to receive the machinery. Fifty miles of wire will be required, which with the poles, will cost about $15,000.

NORTH TROY.—C. O. Fowler, owner of the plant run under the style of the North Troy Electric Light Company, has arranged to extend the line to the station, which will necessitate an all-night service. Heretofore the plant has been operated on a midnight schedule.

NORTHFIELD.—The municipal electric light plant was destroyed by fire on the 3d ult. The total loss was estimated at $20,000, with $10,000 insurance. The Almon-Moody plant at Moretown has been furnishing power for the lights since the city plant was burned. The Council is now considering whether to rebuild and equip the old power house or to purchase the necessary current for running the lights.

BRADFORD.—C. A. Prouty, of Newport, is reported to have purchased the mill property and water power of B. S. Hooker at Bradford, and a controlling interest in the Bradford Electric Lighting Company. He proposes in the spring to fully develop the power now owned by himself and the Electric Lighting Company. The power house will be located on the south side of the stream, and will be built of brick, made fireproof, fully equipped with modern machinery and run the entire twenty-four hours.

VIRGINIA.

STAUNTON.—The Board of Trade has passed resolutions petitioning the Council to enlarge the city electric plant.

CAPE CHARLES.—Heckle & Kellogg have applied to the Town Council of this city for a franchise to erect an electric light plant to furnish lights for the city. The plant will soon be erected.

LURAY.—A charter has been granted to the Luray Electric Company, with a capital of $15,000, to operate an electric light plant. E. C. Harnsberger is president and R. T. Morrison, secretary.

RICHMOND.—Reports state that at a conference of the Committees on Finance and Electricity a sub-committee of five was appointed with authority to employ an expert electrical engineer to prepare estimates of the cost, location, etc., for a municipal electric light plant.

MARTINSVILLE.—An option has been secured on the land and water power owned by R. J. Reynolds on the south side of Smith River, the same to be used as a site for a municipal electric light plant. The cost of the plant is estimated at $60,000. Bonds to that amount will probably be issued soon.

WINCHESTER.—At the recent monthly meeting of the City Council a report on the question of municipal ownership of electric street lights was submitted by Shirley Carter, chairman of the committee to whom the matter had been referred. Mr. Carter's report strongly advocated the city owning its own electric light plant, and the Council has taken the initiatory steps to that end. The question of municipal ownership of the electric light plant was raised several weeks ago, when the Winchester Gas & Electric Light Company, the owner of the present contract, informed the Council that it would charge $70 per lamp per year in future, instead of $55, which the city has been paying. The contract expires in December.

WASHINGTON.

NORTH YAKIMA.—It is reported that the Yakima Water, Light & Power Company will construct a new power plant near the intake of Wapatox ditch to generate electricity for this city and the electric railway.

SEATTLE.—An election will be held December 6 to vote on the issue of bonds as follows: $175,000 for the construction of a city jail, municipal court and hospital, and $250,000 for extensions and improvements to the present light plant. It has been decided to purchase the circuits of the Seattle Electric Company, for which $52,743.73 will be paid it is said.

SPOKANE.—D. L. Huntington, general manager of the Washington Water Power Company, states that it will be but a short time until conditions at Post Falls will be materially changed. The company will eventually have a power plant there with a total capacity of 18,000 horse-power. It is stated that the company expects in the near future to begin extensive improvements on its Spokane plant.

SEATTLE.—The Snoqualmie Falls Power Company has been reorganized under the name of the Seattle-Tacoma Power Company and its capital increased to $3,500,000. Extensive improvements are in contemplation by the company, including the installation of a 5000-kw. generator driven by a 9500-h.p. water wheel, which will practically double the capacity of the plant. The officers are: President, N. H. Latimer; treasurer, O. D. Calvin; general manager and secretary, Thomas B. Hardin; auditor, W. E. Best. The company will own the power plant at Snoqualmie Falls, as well as the properties in Seattle and Tacoma formerly operated under the names of the Seattle Cataract Company and the Tacoma Cataract Company. The White River Power Company, which is now building a big power plant with Lake Tapps, in Pierce County, as the main reservoir, will continue an independent corporation for the present, but will in all probability be merged later with the main corporation.

SEATTLE.—At the immense plant of the Puget Sound Power Company, located near this city, there are four General Electric revolving-field generators of 3500 kilowatts capacity each, with an overload capacity of 25 per cent. for two hours. Two 150-kw., 125-volt, 600 r.p.m. shunt-wound exciters are provided, each direct-connected to an overhung Pelton water wheel and to a 2080-volt, 200-h.p. three-phase induction motor. There are three banks of transformers installed at the power house, each bank consisting of three 2333-kw. water-cooled, oil-insulated, General Electric machines. These transformers have been operated at 55,000 volts from the beginning. For connecting each generator and transformer bank to the low-tension bus-bars a full complement of motor-operated oil switches is provided. Between each generator and each set of 2300-volt bus-bars there are two sets of disconnecting switches and a triple pole General Electric type H, 1200-amp. oil switch. Between the high-tension bus-bars and transformer banks there is a General Electric 60,000-volt, 400-amp. motor-operated oil switch and a set of disconnecting switches on either side of the oil switch. Each generator panel contains three ammeters, one voltmeter, a polyphase indicating wattmeter, a polyphase integrating wattmeter and a field ammeter. Each outgoing line panel contains three ammeters and the totaling panel contains a power factor indicator, a frequency indicator, a curve-drawing voltmeter and three curve-drawing instruments. These instruments belong to a type lately developed by the General Electric Company.

WISCONSIN.

MARKESAN.—The citizens have voted to issue bonds for the construction of an electric light plant.

KENOSHA.—Mayor James Gorman is said to have recommended the construction of a municipal electric light plant.

FENNIMORE.—The town is rejoicing in the possession of a new water and electric light plant which cost $20,000. The plant is owned by the town.

CORLISS.—The Brown-Corliss Engine Company has secured a franchise to erect water works and an electric light, heat and power plant here in the spring. The company expects to spend about $50,000 on the project. At present the town has no fire protection.

MAUSTON.—The Mauston Electric Service Company has acquired the light and telephone systems here. The plants will be remodelled and either a new dam constructed or the old one rebuilt.

NEW RICHMOND.—The new concrete dam of the Chicago Gas & Investment Company at Riverdale, on the Apple River, five miles northwest, is nearly completed. It will have a 23-foot head and develop 500 horse-power, costing, complete, $500,000. This is the fourth dam on Apple River, the total capacity being 2000 horse-power, and there is still room for two more dams to develop 500 horse-power each. The cost of equipment up to date is over $2,000,000. Most of the power is used in St. Paul and Stillwater.

WYOMING.

LANDER.—Edward Fanning, of Stewartsville, Minn., writes that he, with R. A. Morse, of this city, is interested in the construction of an electric power plant here to cost $50,000. The power will be used for running mines.

THERMOPOLIS.—The Thermopolis Electric Light & Power Company has announced its intention of building a new plant on the river above town. The old plant, which was supplied with power by water from the hot springs, was destroyed by fire recently. The new plant is to be located farther up the river and will derive power from cold water direct from the river. The company is understood to be in the market for an electrician who understands water power; all-night run; pay $100 per month.

CANADA.

NIAGARA FALLS, ONT.—The Electrical Development Company, Ltd., of Ontario, has awarded contracts, it is said, to the amount of $120,000 in connection with a proposed new power station.

VANCOUVER, B. C.—The Stave Falls Power Company has decided to issue $900,000, the proceeds to be devoted to the development of water power. The falls are about forty miles from New Westminster and it is estimated that about 25,000 horse-power is available.

CHARLOTTETOWN, P. E. I.—The City Council has engaged the De Lano Osborn Engineering Company, of Montreal, to prepare plans and estimates for a civic light and power plant. The question will be fully investigated before renewing any of the existing contracts with the local companies.

VICTORIA, B. C.—The Victoria Power Company has been organized, with authority to issue $750,000 bonds for the purpose of diverting the water from Koksilah River to Shawnigan Lake and conveying it to Mill Bay. The energy obtained will be used for industrial lighting and street railway service in Victoria and Esquimault.
